Preface

The roots of the Power ISA (Instruction Set Architecture) extend back over a quarter of a century, to IBM Research. The POWER (Performance Optimization With Enhanced RISC) Architecture was introduced with the RISC System/6000 product family in early 1990. In 1991, Apple, IBM, and Motorola began the collaboration to evolve to the PowerPC Architecture, expanding the architecture's applicability. In 1997, Motorola and IBM began another collaboration, focused on optimizing PowerPC for embedded systems, which produced Book E.

In 2006, Freescale and IBM collaborated on the creation of the Power ISA Version 2.03, which represented the reunification of the architecture by combining Book E content with the more general purpose PowerPC Version 2.02. A significant benefit of the reunification is the establishment of a single, compatible, 64-bit programming model. The combining also extends explicit architectural endorsement and control to Auxiliary Processing Units (APUs), units of function that were originally developed as implementation- or product family-specific extensions in the context of the Book E allocated opcode space. With the resulting architectural superset comes a framework that clearly establishes requirements and identifies options.

To a very large extent, application program compatibility has been maintained throughout the history of the architecture, with the main exception being application exploitation of APUs. The framework identifies the base, pervasive, part of the architecture, and differentiates it from "categories" of optional function (see Section 1.3.5 of Book I). Because of the substantial differences in the supervisor (privileged) architecture that developed as Book E was optimized for embedded systems, the supervisor architectures for embedded and general purpose implementations are represented as mutually exclusive categories. Future versions of the architecture will seek to converge on a common solution where possible.

This document defines the Power ISA Version 2.06. It is comprised of five books and a set of appendices.

Book I, *Power ISA User Instruction Set Architecture*, covers the base instruction set and related facilities available to the application programmer. It includes five chapters derived from APU function, including the vector extension also known as Altivec.

Book II, *Power ISA Virtual Environment Architecture*, defines the storage model and related instructions and facilities available to the application programmer.

Book III-S, *Power ISA Operating Environment Architecture*, defines the supervisor instructions and related facilities used for general purpose implementations.

Book III-E, *Power ISA Operating Environment Architecture*, defines the supervisor instructions and related facilities used for embedded implementations. It was derived from Book E and extended to include APU function.

Book VLE, *Power ISA Variable Length Encoded Instructions Architecture*, defines alternative instruction encodings and definitions intended to increase instruction density for very low end implementations. It was derived from an APU description developed by Freescale Semiconductor.

As used in this document, the term "Power ISA" refers to the instructions and facilities described in Books I, II, III-S, III-E, and VLE.

Usage of the phrase "Book III" refers to both Book III-S and Book III-E. An exception to this rule is when, at the beginning of a Section or Book, it is specified that usage of the phrase "Book III" implies only either "Book III-S" or "Book III-E".

Change bars have been included to indicate changes from the Power ISA Version 2.05.

Summary of Changes in Power ISA Version 2.06

This version of the PowerISA was created by applying the following requests for change (RFCs) to PowerISA version 2.06.

Fixed-Point Extended Precision Instructions: Four new divide instructions are added. The divide instructions assist in dividing 64 and 128 bit dividends by 32 and 64-bit divisors, respectively. Among other uses, these instructions can be used to provide better performance for extended-precision fixed-point divide operations. See Sections 3.3.8 and 3.3.8.1 of Book I.

Bit Permute Instruction: A new instruction is added to provide high-speed bit permutations. See Section 3.3.13.1 of Book I.

Additional Population Count Instructions: 32-bit and 64-bit versions of the *Population Count* instructions are added. See Sections 3.3.12 and 3.3.13.1 of Book I.

Software Initiated Stride-N Prefetching: A new stream variant of *dcbt* and *dcbst* enables the specification of stride and first element offset. See Section 4.3.2 of Book II.

Load/Store Doubleword Byte-Reverse Instructions: Doubleword versions of the byte-reversed *Load* and *Store* instructions are added. See Section 3.3.4.1 of Book I.

Remove Hypervisor Data and Instruction Segment Interrupts and Reuse Interrupt Vectors: The Hypervisor Data and Instruction Segment interrupts that were added for Virtualized Partition Memory in V. 2.04 are removed.

Change Category of VRSAVE Register to Base: The VRSAVE register, which had been part of the Vector and Embedded categories, is made Category: Base. See Section 3.2.3 of Book I.

Vector-Scalar Floating-Point Operations: The FPRs are doubled in width and the VRs appended to them to form a 64 entry by 128b register file. Existing BFP, DFP, and Vector instructions continue to operate on their respective parts of the expanded register file. Double-precision vector and scalar instructions and single-precision vector instructions are added which operate on the entire register file. See Chapter 7 of Book I.

Extensions to BFP Integer Conversion Instruction Set: New double-precision floating-point to unsigned integer word/doubleword conversion instructions and new signed and unsigned integer word/doubleword to double-precision/single-precision conversion instructions are added. See Sections 4.6.2 and 4.6.7.2 of Book I.

Processor Compatibility Register: The PCR is updated to control newly added facilities in Version 2.06. See Section 2.6 of Book III-S.

tlbiel with Invalidation Selector (IS): An IS field is added to the GPR operand of *tlbiel* to specify whether the invalidation is for a specific virtual address, for all entries in a specific congruence class that have matching LPID, or for all entries in a specific congruence class regardless of LPID. See Section 5.9.3.3 of Book III-S.

tlbie[] instructions with LPID operand: The *tlbie[]* instructions are enhanced to allow a GPR to specify an LPID value. The L field in the *tlbie[]* instructions is moved to GPR RB. See Section 5.9.3.3 of Book III-S.

Privileged, nonhypervisor tlbiel: The *tlbiel* instruction is enhanced to allow an OS to execute it. See Section 5.9.3.3 of Book III-S.

Edge-triggered Hypervisor Decrementer Exception: A Hypervisor Decrementer interrupt occurs when HDEC₃₂ changes from 0 to 1, except when a processor is in a power-saving mode. See Section 7.4 of Book III-S.

Extensions to BFP Instruction Set to Support Software Divide and Square Root: Two new instructions are added to enable effective, IEEE-compliant software divide and square root, which can more effectively utilize hardware pipeline latencies, See Section 4.6.6.1 of Book I.

Data Cache Block Touch - Transient: A new variant of *dcbt* is added that hints that usage of a soon-to-be-referenced datum is transient, so that the processor can avoid displacing non-transient data from the cache. See Section 4.3.2 of Book II.

AMR-Related Architecture Changes (AMOR, UAMOR, etc.): Two new SPRs, called Authority Mask Override Register (AMOR) and User Authority Mask Override Register (UAMOR), are added to the architecture to restrict updates to the AMR by operating systems and application programs respectively. A new, non-privileged, SPR number for the AMR is added to permit application programs to access the AMR. See Section 5.7.9.1 of Book III-S.

Real Mode Storage Control Extension: A more flexible history-based approach to RMSC is added that can cover all of well-behaved data storage. If the initial data access to any portion of storage is not Caching Inhibited, it is performed as Guarded, but subsequent accesses will be performed as non-Guarded. If the initial access is Caching Inhibited, all accesses will be performed as Guarded. See Section 5.7.3.3.1 of Book III-S.

MPSS Extension: More combinations of page sizes are allowed in a segment. See Section 5.7.7.1 of Book III-S.

Strong Access Ordering: An assist for X86 and Sparc application emulation and porting provides TSO (Total Store Order, reference Sparc architecture) for

accesses to designated pages in memory. See Section 1.6.7 of Book II.

Remove the L Field from *fre* and *frsqrite*: The L field that was added to *fre* and *frsqrite* in V. 2.05 is removed.

Mismatched Store Conditional: A new Store Conditional Page Mobility (SCPM) category is defined to specify that if a reservation exists, then a *Store Conditional* instruction's store is not performed if the storage operand is in a different real memory block than the reservation, where the size of the block is the size of the smallest real page supported by the implementation. In this case CR0_{EQ} is set to indicate that the store is not performed. Also, if a *Store Conditional* instruction has a different storage operand length than the previous *Load and Reserve* instruction and the reservation exists, both the setting of CR0_{EQ} and whether the store is performed are undefined. See Sections 1.7.3 and 1.7.3.1 of Book II.

Miscellaneous Changes: Various minor editorial corrections are made.

Embedded Hypervisor: Logical partitioning / hypervisor capabilities are added to the Embedded environment. See Chapter 2 of Book III-E.

Embedded Interrupt Fixed Offsets: Embedded IVORs are replaced with fixed offsets. An optional Machine Check Interrupt Vector Prefix Register is also added so that the Machine Check handler can be located in storage that is not Caching Inhibited. See Sections 7.2.18.4 and 7.6.2 of Book III-E.

Multi-threading Architecture: Multi-threading and associated resources are defined for the Embedded environment. The necessary definitions are also added to Book III-S, and the terminology in both Book IIIs is modified to use "thread" instead of "processor" where appropriate. See Chapter 3 of Book III-E.

FSL MMU with Embedded Hypervisor Support & Extensions plus Embedded Page Table: The FSL Type MMU becomes the standard for the Embedded environment. Hypervisor capability is added to it, and the allowance for multiple PID registers is removed. A new MMU Architecture Version 2.0 is defined that includes an optional hardware page table, an optional conditional TLB write based on a TLB-reservation, a Logical to Real Address Translation facility to permit OS TLB and/or page table management, and additional 2ⁿ KB page sizes. It also allows for a different TLB scheme, including a hardware entry select capability. The *tlbivax* TLB invalidate all function is removed from Version 2.0. MAS register pairs can be read/written by *mfspr/mtspr* on 64-bit implementations. See Chapter 6 of Book III-E.

Move *evlddpx* and *evstddpx* Opcodes: The opcodes for *evlddpx* and *evstddpx* are changed. See Section 5.4.3 of Book III-E.

Byte and Halfword Reservations: New byte and halfword *Load and Reserve* and *Store Conditional* instructions are added to accelerate byte and halfword atomic update processing. Also, in Book III-S Appendix D, the recommended treatment of DSISR values that correspond to multiple instructions is changed, to state that in these cases the interrupt handler should load the instruction from storage and, if the instruction is *Load and Reserve*, should treat the case as a programming error. See Section 4.4.2 of Book II.

Decorated Storage: New fixed-point *Load* and *Store* instructions are added that operate on "decorated storage" and allow the programmer to supply meta-data to accompany the storage operation. See Chapter 6 of Book II.

Embedded Floating Point *efscfd* Change: When an *efscfd* instruction operates on a double-precision value that is smaller than the smallest normalized single-precision value, the result of the conversion is the appropriate signed zero. See Section 9.3.4 of Book I.

Delete *mfpidi* instruction: The *mfpidi* instruction is removed from the architecture.

Make *mftb* Phased-Out for both Embedded and Server Environments: *mftb* was formerly Phased-Out for the Server environment, and is now Phased-Out for both environments.

wait Instruction Changes: A new field is added to the *wait* instruction to add reservation loss and an implementation-specific condition as causes for resuming instruction execution. Also, *wait* is no longer context synchronizing. See Section 4.4.4 of Book II.

Remove the Version Number from Phased-In Category: The "(sV2.0x)" suffix is removed from the Phased-In Category.

CFAR Relaxation: B-form branches within the current cache block or to an adjacent cache block need not set the CFAR. See Section 8.1.1 of Book III-S.

Limitations on Implementation-Specific Features: An Engineering Note is added in Book III-E specifying the SPR numbers that Embedded designs should use for implementation-specific SPRs. The Engineering Note in the Preface is made consistent with the needs of Embedded designs. See Section 5.4.1 of Book III-E.

Handling of High-Order GPR Bits in 32-bit Mode of Embedded Designs: For Embedded 64-bit designs, adds the option for a 32-bit mode that is compatible with that of the Server environment. See Section 1.5.2 of Book I.

Interrupts and DABR Match for Quadword and Zero-Length Storage Operands: DABR match and [H]DAR setting by [H]DSI and Data Segment interrupts have quadword granularity for quadword storage operands. 0-length storage operands do not cause [H]DSI or

Alignment interrupts, and do not cause Reference and Change bits to be set.

Adjustments for Secure Systems: The options for some instructions to cause reservation loss is removed. ***dcbtst***, ***dcbtstep***, and ***dcbtstls*** are changed to require write authority but prevented from setting the Change

bit. The descriptions of ***dcbtep*** and ***dcbtstep*** are updated to clarify that they do not support stream prefetch. See Section 1.7.3.1 of Book II.

Restore bcl 20.31.\$+4 Idiom to Programming Note: Restore the idiom used to get the next instruction address. See Section 2.4 of Book I.

6.10.1	Vector Floating-Point Arithmetic	
	Instructions	259
6.10.2	Vector Floating-Point Maximum and	
	Minimum Instructions	261
6.10.3	Vector Floating-Point Rounding and	
	Conversion Instructions	262
6.10.4	Vector Floating-Point Compare	
	Instructions	265
6.10.5	Vector Floating-Point Estimate	
	Instructions	267
6.11	Vector Status and Control Register	
	Instructions	269

Chapter 7. Vector-Scalar Floating-Point Operations [Category: VSX] 271

7.1	Introduction	273
7.1.1	Overview of the Vector-Scalar	
	Extension	273
7.1.1.1	Compatibility with Category	
	Floating-Point and Category Decimal	
	Floating-Point Operations	273
7.1.1.2	Compatibility with Category Vector	
	Operations	273
7.2	VSX Registers	273
7.2.1	Vector-Scalar Registers	273
7.2.1.1	Floating-Point Registers	274
7.2.1.2	Vector Registers	275
7.2.2	Floating-Point Status and Control	
	Register	276
7.3	VSX Operations	282
7.3.1	VSX Floating-Point Arithmetic	
	Overview	282
7.3.2	VSX Floating-Point Data	283
7.3.2.1	Data Format	283
7.3.2.2	Value Representation	284
7.3.2.3	Sign of Result	285
7.3.2.4	Normalization and	
	Denormalization	285
7.3.2.5	Data Handling and Precision	286
7.3.2.6	Rounding	287
7.3.3	VSX Floating-Point Execution	
	Models	289
7.3.3.1	VSX Execution Model for IEEE	
	Operations	289
7.3.3.2	VSX Execution Model for	
	Multiply-Add Type Instructions	290
7.4	VSX Floating-Point Exceptions	292
7.4.1	Floating-Point Invalid Operation	
	Exception	295
7.4.1.1	Definition	295
7.4.1.2	Action for VE=1	295
7.4.1.3	Action for VE=0	297
7.4.2	Floating-Point Zero Divide	
	Exception	302
7.4.2.1	Definition	302
7.4.2.2	Action for ZE=1	302
7.4.2.3	Action for ZE=0	302
7.4.3	Floating-Point Overflow	
	Exception	304
7.4.3.1	Definition	304
7.4.3.2	Action for OE=1	304
7.4.3.3	Action for OE=0	304
7.4.4	Floating-Point Underflow	
	Exception	306
7.4.4.1	Definition	306
7.4.4.2	Action for UE=1	306
7.4.4.3	Action for UE=0	307

7.4.5 Floating-Point Inexact		7.7.1 Instruction Description	
Exception	308	Conventions	322
7.4.5.1 Definition	308	7.7.1.1 Instruction RTL Operators	322
7.4.5.2 Action for XE=1	308	7.7.1.2 Instruction RTL Function	
7.4.5.3 Action for XE=0	308	Calls	322
7.5 Storage Access Operations	310		
7.5.1 Accessing Aligned Storage		Chapter 8. Signal Processing Engine	
Operands	310	(SPE) [Category: Signal Processing	
7.5.2 Accessing Unaligned Storage		Engine]	503
Operands	311	8.1 Overview	503
7.5.3 Storage Access Exceptions	312	8.2 Nomenclature and Conventions	503
7.6 VSX Instruction Set Summary	313	8.3 Programming Model	504
7.6.1 VSX Storage Access		8.3.1 General Operation	504
Instructions	313	8.3.2 GPR Registers	504
7.6.1.1 VSX Scalar Storage Access		8.3.3 Accumulator Register	504
Instructions	313	8.3.4 Signal Processing Embedded	
7.6.1.2 VSX Vector Storage Access		Floating-Point Status and Control Register	
Instructions	313	(SPEFSCR)	504
7.6.2 VSX Move Instructions	314	8.3.5 Data Formats	507
7.6.2.1 VSX Scalar Move		8.3.5.1 Integer Format	507
Instructions	314	8.3.5.2 Fractional Format	507
7.6.2.2 VSX Vector Move		8.3.6 Computational Operations	508
Instructions	314	8.3.7 SPE Instructions	509
7.6.3 VSX Floating-Point Arithmetic		8.3.8 Saturation, Shift, and Bit Reverse	
Instructions	315	Models	509
7.6.3.1 VSX Scalar Floating-Point		8.3.8.1 Saturation	509
Arithmetic Instructions	315	8.3.8.2 Shift Left	509
7.6.3.2 VSX Vector Floating-Point		8.3.8.3 Bit Reverse	509
Arithmetic Instructions	315	8.3.9 SPE Instruction Set	510
7.6.4 VSX Floating-Point Compare			
Instructions	317	Chapter 9. Embedded Floating-Point	
7.6.4.1 VSX Scalar Floating-Point		[Category: SPE.Embedded Float	
Compare Instructions	317	Scalar Double]	
7.6.4.2 VSX Vector Floating-Point		[Category: SPE.Embedded Float	
Compare Instructions	317	Scalar Single]	
7.6.5 VSX DP-SP Conversion		[Category: SPE.Embedded Float	
Instructions	318	Vector]	557
7.6.5.1 VSX Scalar DP-SP Conversion		9.1 Overview	557
Instructions	318	9.2 Programming Model	558
7.6.5.2 VSX Vector DP-SP Conversion		9.2.1 Signal Processing Embedded	
Instructions	318	Floating-Point Status and Control Register	
7.6.6 VSX Integer Conversion		(SPEFSCR)	558
Instructions	318	9.2.2 Floating-Point Data Formats	558
7.6.6.1 VSX Scalar Integer Conversion		9.2.3 Exception Conditions	559
Instructions	318	9.2.3.1 Denormalized Values on	
7.6.6.2 VSX Vector Integer Conversion		Input	559
Instructions	319	9.2.3.2 Embedded Floating-Point Overflow	
7.6.7 VSX Round to Floating-Point Integer		and Underflow	559
Instructions	320	9.2.3.3 Embedded Floating-Point Invalid	
7.6.7.1 VSX Scalar Round to Floating-		Operation/Input Errors	560
Point Integer Instructions	320	9.2.3.4 Embedded Floating-Point Round	
7.6.7.2 VSX Vector Round to Floating-		(Inexact)	560
Point Integer Instructions	320	9.2.3.5 Embedded Floating-Point Divide by	
7.6.8 VSX Logical Instructions	320	Zero	560
7.6.9 VSX Permute Instructions	321		
7.7 VSX Instruction Descriptions	322		

9.2.3.6 Default Results	560	Appendix C. Vector RTL Functions	
9.2.4 IEEE 754 Compliance	560	[Category: Vector]	619
9.2.4.1 Sticky Bit Handling For Exception		Appendix D. Embedded Floating-	
Conditions	561	Point RTL Functions	
9.3 Embedded Floating-Point		[Category: SPE.Embedded Float	
Instructions	562	Scalar Double]	
9.3.1 Load/Store Instructions	562	[Category: SPE.Embedded Float	
9.3.2 SPE.Embedded Float Vector		Scalar Single]	
Instructions [Category: SPE.Embedded		[Category: SPE.Embedded Float	
Float Vector]	562	Vector]	621
9.3.3 SPE.Embedded Float Scalar Single		D.1 Common Functions	621
Instructions		D.2 Convert from Single-Precision	
[Category: SPE.Embedded Float Scalar		Embedded Floating-Point to Integer Word	
Single]	570	with Saturation	622
9.3.4 SPE.Embedded Float Scalar Double		D.3 Convert from Double-Precision	
Instructions		Embedded Floating-Point to Integer Word	
[Category: SPE.Embedded Float Scalar		with Saturation	623
Double]	577	D.4 Convert from Double-Precision	
9.4 Embedded Floating-Point Results		Embedded Floating-Point to Integer	
Summary	586	Doubleword with Saturation	624
		D.5 Convert to Single-Precision	
		Embedded Floating-Point from Integer	
		Word	625
		D.6 Convert to Double-Precision	
		Embedded Floating-Point from Integer	
		Word	625
		D.7 Convert to Double-Precision	
		Embedded Floating-Point from Integer	
		Doubleword	626
Chapter 10. Legacy Move Assist		Appendix E. Assembler Extended	
Instruction [Category: Legacy Move		Mnemonics	627
Assist]	591	E.1 Symbols	627
		E.2 Branch Mnemonics	628
		E.2.1 BO and BI Fields	628
		E.2.2 Simple Branch Mnemonics	628
		E.2.3 Branch Mnemonics Incorporating	
		Conditions	629
		E.2.4 Branch Prediction	630
		E.3 Condition Register Logical	
		Mnemonics	631
		E.4 Subtract Mnemonics	631
		E.4.1 Subtract Immediate	631
		E.4.2 Subtract	631
		E.5 Compare Mnemonics	632
		E.5.1 Doubleword Comparisons	632
		E.5.2 Word Comparisons	632
		E.6 Trap Mnemonics	633
		E.7 Rotate and Shift Mnemonics	635
		E.7.1 Operations on Doublewords	635
		E.7.2 Operations on Words	636
		E.8 Move To/From Special Purpose	
		Register Mnemonics	637
Chapter 11. Legacy Integer Multiply-			
Accumulate Instructions [Category:			
Legacy Integer			
Multiply-Accumulate]	593		
Appendix A. Suggested Floating-			
Point Models [Category: Floating-			
Point]	603		
A.1 Floating-Point Round to Single-			
Precision Model	603		
A.2 Floating-Point Convert to Integer			
Model	607		
A.3 Floating-Point Convert from Integer			
Model	610		
A.4 Floating-Point Round to Integer			
Model	612		
Appendix B. Densely Packed			
Decimal	615		
B.1 BCD-to-DPD Translation	615		
B.2 DPD-to-BCD Translation	615		
B.3 Preferred DPD encoding	616		

E.9 Miscellaneous Mnemonics	637
---------------------------------------	-----

Appendix F. Programming

Examples	641
F.1 Multiple-Precision Shifts	641
F.2 Floating-Point Conversions [Category: Floating-Point]	644
F.2.1 Conversion from Floating-Point Number to Floating-Point Integer	644
F.2.2 Conversion from Floating-Point Number to Signed Fixed- Point Integer Doubleword	644
F.2.3 Conversion from Floating-Point Number to Unsigned Fixed- Point Integer Doubleword	644
F.2.4 Conversion from Floating-Point Number to Signed Fixed- Point Integer Word	644
F.2.5 Conversion from Floating-Point Number to Unsigned Fixed- Point Integer Word	645
F.2.6 Conversion from Signed Fixed-Point Integer Doubleword to Floating-Point Number	645
F.2.7 Conversion from Unsigned Fixed- Point Integer Doubleword to Floating-Point Number	645
F.2.8 Conversion from Signed Fixed-Point Integer Word to Floating-Point Number	645
F.2.9 Conversion from Unsigned Fixed- Point Integer Word to Floating-Point Number	645
F.2.10 Unsigned Single-Precision BCD Arithmetic	646
F.2.11 Signed Single-Precision BCD Arithmetic	646
F.2.12 Unsigned Extended-Precision BCD Arithmetic	646
F.3 Floating-Point Selection [Category: Floating-Point]	648
F.3.1 Comparison to Zero	648
F.3.2 Minimum and Maximum	648
F.3.3 Simple if-then-else Constructions	648
F.3.4 Notes	648
F.4 Vector Unaligned Storage Operations [Category: Vector]	649
F.4.1 Loading a Unaligned Quadword Using Permute from Big-Endian Storage	649

Book II:

Power ISA Virtual Environment Architecture	651
---	------------

Chapter 1. Storage Model 653

1.1 Definitions	653
1.2 Introduction	654
1.3 Virtual Storage	655
1.4 Single-copy Atomicity	655
1.5 Cache Model	656
1.6 Storage Control Attributes	656
1.6.1 Write Through Required	657
1.6.2 Caching Inhibited	657
1.6.3 Memory Coherence Required [Category: Memory Coherence]	657
1.6.4 Guarded	658
1.6.5 Endianness [Category: Embedded.Little-Endian]	658
1.6.6 Variable Length Encoded (VLE) Instructions	658
1.6.7 Strong Access Order [Category: SAO]	659
1.7 Shared Storage	660
1.7.1 Storage Access Ordering	660
1.7.2 Storage Ordering of I/O Accesses	662
1.7.3 Atomic Update	662
1.7.3.1 Reservations	663
1.7.3.2 Forward Progress	665
1.8 Instruction Storage	665
1.8.1 Concurrent Modification and Execution of Instructions	668

Chapter 2. Effect of Operand Placement on Performance 671

2.1 Instruction Restart	673
-----------------------------------	-----

Chapter 3. Management of Shared Resources 675

3.1 Program Priority Registers	675
3.2 “or” Instruction	676

Chapter 4. Storage Control Instructions 677

4.1 Parameters Useful to Application Programs	677
4.2 Data Stream Control Register (DSCR) [Category: Stream]	678
4.3 Cache Management Instructions	679
4.3.1 Instruction Cache Instructions	680
4.3.2 Data Cache Instructions	681

- 4.3.2.1 Obsolete Data Cache Instructions [Category: Vector.Phased-Out]692
- 4.4 Synchronization Instructions693
 - 4.4.1 Instruction Synchronize Instruction693
 - 4.4.2 Load and Reserve and Store Conditional Instructions693
 - 4.4.2.1 64-Bit Load and Reserve and Store Conditional Instructions [Category: 64-Bit]699
 - 4.4.3 Memory Barrier Instructions701
 - 4.4.4 Wait Instruction704

- Chapter 5. Time Base 707**
 - 5.1 Time Base Overview707
 - 5.2 Time Base707
 - 5.2.1 Time Base Instructions708
 - 5.3 Alternate Time Base [Category: Alternate Time Base]710

- Chapter 6. Decorated Storage Facility [Category: Decorated Storage] 711**
 - 6.1 Decorated Load Instructions712
 - 6.2 Decorated Store Instructions713
 - 6.3 Decorated Notify Instructions714

- Chapter 7. External Control [Category: External Control] 715**
 - 7.1 External Access Instructions716

- Appendix A. Assembler Extended Mnemonics 717**
 - A.1 Data Cache Block Flush Mnemonics717
 - A.2 Load and Reserve Mnemonics717
 - A.3 Synchronize Mnemonics717
 - A.4 Wait Mnemonics717

- Appendix B. Programming Examples for Sharing Storage 719**
 - B.1 Atomic Update Primitives719
 - B.2 Lock Acquisition and Release, and Related Techniques721
 - B.2.1 Lock Acquisition and Import Barriers721
 - B.2.1.1 Acquire Lock and Import Shared Storage721
 - B.2.1.2 Obtain Pointer and Import Shared Storage721
 - B.2.2 Lock Release and Export Barriers722

- B.2.2.1 Export Shared Storage and Release Lock 722
- B.2.2.2 Export Shared Storage and Release Lock using lwsync 722
- B.2.3 Safe Fetch 722
- B.3 List Insertion 723
- B.4 Notes 723

Book III-S:

- Power ISA Operating Environment Architecture - Server Environment [Category: Server] 725**

- Chapter 1. Introduction 727**
 - 1.1 Overview 727
 - 1.2 Document Conventions 727
 - 1.2.1 Definitions and Notation 727
 - 1.2.2 Reserved Fields 728
 - 1.3 General Systems Overview 729
 - 1.4 Exceptions 729
 - 1.5 Synchronization 729
 - 1.5.1 Context Synchronization 729
 - 1.5.2 Execution Synchronization 730

- Chapter 2. Logical Partitioning (LPAR) 731**
 - 2.1 Overview 731
 - 2.2 Logical Partitioning Control Register (LPCR) 731
 - 2.3 Real Mode Offset Register (RMOR) 734
 - 2.4 Hypervisor Real Mode Offset Register (HRMOR) 734
 - 2.5 Logical Partition Identification Register (LPIDR) 734
 - 2.6 Processor Compatibility Register (PCR) 735
 - 2.7 Other Hypervisor Resources 737
 - 2.8 Sharing Hypervisor Resources 738
 - 2.9 Hypervisor Interrupt Little-Endian (HILE) Bit 739

- Chapter 3. Branch Facility 741**
 - 3.1 Branch Facility Overview 741
 - 3.2 Branch Facility Registers 741
 - 3.2.1 Machine State Register 741
 - 3.3 Branch Facility Instructions 745
 - 3.3.1 System Linkage Instructions 745
 - 3.3.2 Power-Saving Mode Instructions 747
 - 3.3.2.1 Entering and Exiting Power-Saving Mode 751

Chapter 4. Fixed-Point Facility . . 753

4.1	Fixed-Point Facility Overview	753
4.2	Special Purpose Registers	753
4.3	Fixed-Point Facility Registers	753
4.3.1	Processor Version Register	753
4.3.2	Processor Identification Register	754
4.3.3	Control Register	754
4.3.4	Program Priority Register	754
4.3.5	Software-use SPRs	755
4.4	Fixed-Point Facility Instructions	756
4.4.1	Fixed-Point Load and Store Caching Inhibited Instructions	756
4.4.2	Fixed-Point Load and Store Quadword Instructions [Category: Load/Store Quadword]	759
4.4.3	OR Instruction	760
4.4.4	Move To/From System Register Instructions	760

Chapter 5. Storage Control 769

5.1	Overview	770
5.2	Storage Exceptions	770
5.3	Instruction Fetch	770
5.3.1	Implicit Branch	770
5.3.2	Address Wrapping Combined with Changing MSR Bit SF	770
5.4	Data Access	770
5.5	Performing Operations Out-of-Order	770
5.6	Invalid Real Address	771
5.7	Storage Addressing	773
5.7.1	32-Bit Mode	773
5.7.2	Virtualized Partition Memory (VPM) Mode	773
5.7.3	Real And Virtual Real Addressing Modes	774
5.7.3.1	Hypervisor Offset Real Mode Address	774
5.7.3.2	Offset Real Mode Address	774
5.7.3.3	Storage Control Attributes for Accesses in Real and Hypervisor Real Addressing Modes	775
5.7.3.3.1	Hypervisor Real Mode Storage Control	775
5.7.3.4	Virtual Real Mode Addressing Mechanism	776
5.7.3.5	Storage Control Attributes for Implicit Storage Accesses	777
5.7.4	Address Ranges Having Defined Uses	777
5.7.5	Address Translation Overview	777
5.7.6	Virtual Address Generation	778
5.7.6.1	Segment Lookaside Buffer (SLB)	778
5.7.6.2	SLB Search	779

5.7.7	Virtual to Real Translation	780
5.7.7.1	Page Table	782
5.7.7.2	Storage Description Register 1	784
5.7.7.3	Page Table Search	785
5.7.7.4	Relaxed Page Table Alignment [Category: Server.Relaxed Page Table Alignment]	787
5.7.8	Reference and Change Recording	787
5.7.9	Storage Protection	790
5.7.9.1	Virtual Page Class Key Protection	790
5.7.9.2	Basic Storage Protection, Address Translation Enabled	794
5.7.9.3	Basic Storage Protection, Address Translation Disabled	794
5.8	Storage Control Attributes	796
5.8.1	Guarded Storage	796
5.8.1.1	Out-of-Order Accesses to Guarded Storage	796
5.8.2	Storage Control Bits	797
5.8.2.1	Storage Control Bit Restrictions	798
5.8.2.2	Altering the Storage Control Bits	798
5.9	Storage Control Instructions	800
5.9.1	Cache Management Instructions	800
5.9.2	Synchronize Instruction	800
5.9.3	Lookaside Buffer Management	801
5.9.3.1	SLB Management Instructions	802
5.9.3.2	Bridge to SLB Architecture [Category: Server.Phased-Out]	808
5.9.3.2.1	Segment Register Manipulation Instructions	808
5.9.3.3	TLB Management Instructions	811
5.10	Page Table Update Synchronization Requirements	818
5.10.1	Page Table Updates	818
5.10.1.1	Adding a Page Table Entry	819
5.10.1.2	Modifying a Page Table Entry	820
5.10.1.3	Deleting a Page Table Entry	820

Chapter 6. Interrupts 821

6.1	Overview	821
6.2	Interrupt Registers	822
6.2.1	Machine Status Save/Restore Registers	822
6.2.2	Hypervisor Machine Status Save/Restore Registers	822
6.2.3	Data Address Register	822

6.2.4 Hypervisor Data Address Register	822
6.2.5 Data Storage Interrupt Status Register	822
6.2.6 Hypervisor Data Storage Interrupt Status Register	823
6.2.7 Hypervisor Emulation Instruction Register	823
6.2.8 Hypervisor Maintenance Exception Register	823
6.2.9 Hypervisor Maintenance Exception Enable Register	823
6.3 Interrupt Synchronization	824
6.4 Interrupt Classes	824
6.4.1 Precise Interrupt	824
6.4.2 Imprecise Interrupt	824
6.4.3 Interrupt Processing	825
6.4.4 Implicit alteration of HSRR0 and HSRR1	827
6.5 Interrupt Definitions	828
6.5.1 System Reset Interrupt	829
6.5.2 Machine Check Interrupt	831
6.5.3 Data Storage Interrupt	832
6.5.4 Data Segment Interrupt	833
6.5.5 Instruction Storage Interrupt	834
6.5.6 Instruction Segment Interrupt	834
6.5.7 External Interrupt	835
6.5.8 Alignment Interrupt	835
6.5.9 Program Interrupt	837
6.5.10 Floating-Point Unavailable Interrupt	838
6.5.11 Decrementer Interrupt	839
6.5.12 Hypervisor Decrementer Interrupt	839
6.5.13 System Call Interrupt	839
6.5.14 Trace Interrupt [Category: Trace]	839
6.5.15 Hypervisor Data Storage Interrupt	840
6.5.16 Hypervisor Instruction Storage Interrupt	841
6.5.17 Hypervisor Emulation Assistance Interrupt	842
6.5.18 Hypervisor Maintenance Interrupt	842
6.5.19 Performance Monitor Interrupt [Category: Server.Performance Monitor]	843
6.5.20 Vector Unavailable Interrupt [Category: Vector]	843
6.5.21 VSX Unavailable Interrupt [Category: VSX]	843
6.6 Partially Executed Instructions	844
6.7 Exception Ordering	845

6.7.1 Unordered Exceptions	845
6.7.2 Ordered Exceptions	845
6.8 Interrupt Priorities	845

Chapter 7. Timer Facilities 849

7.1 Overview	849
7.2 Time Base (TB)	849
7.2.1 Writing the Time Base	850
7.3 Decrementer	850
7.3.1 Writing and Reading the Decrementer	851
7.4 Hypervisor Decrementer	851
7.5 Processor Utilization of Resources Register (PURR)	852
7.6 Scaled Processor Utilization of Resources Register (SPURR)	853

Chapter 8. Debug Facilities 855

8.1 Overview	855
8.1.1 Come-From Address Register	855
8.1.2 Data Address Breakpoint	855

Chapter 9. External Control

[Category: External Control] 859

9.1 External Access Register	859
9.2 External Access Instructions	859

Chapter 10. Synchronization Requirements for Context

Alterations. 861

Appendix A. Assembler Extended

Mnemonics 867

A.1 Move To/From Special Purpose Register Mnemonics	867
---	-----

Appendix B. Example Performance

Monitor 869

B.1 PMM Bit of the Machine State Register	870
B.2 Special Purpose Registers	870
B.2.1 Performance Monitor Counter Registers	872
B.2.2 Monitor Mode Control Register 0	872
B.2.3 Monitor Mode Control Register 1	874
B.2.4 Monitor Mode Control Register A	875
B.2.5 Sampled Instruction Address Register	876
B.2.6 Sampled Data Address Register	876

B.3 Performance Monitor	
Interrupt.	876
B.4 Interaction with the Trace Facility .	877
Appendix C. Example Trace	
Extensions.	879
Appendix D. Interpretation of the	
DSISR as Set by an Alignment	
Interrupt.	881
Appendix E. Programming	
Examples.	885
E.1 Unsigned Single-Precision BCD	
Arithmetic	885
E.2 Signed Single-Precision BCD	
Arithmetic	885
E.3 Unsigned Extended-Precision BCD	
Arithmetic	886
Book III-E:	
Power ISA Operating Environment	
Architecture - Embedded	
Environment [Category:	
Embedded]	887
Chapter 1. Introduction	889
1.1 Overview.	889
1.2 32-Bit Implementations.	889
1.3 Document Conventions	889
1.3.1 Definitions and Notation	889
1.3.2 Reserved Fields.	891
1.4 General Systems Overview	891
1.5 Exceptions	892
1.6 Synchronization.	892
1.6.1 Context Synchronization	892
1.6.2 Execution Synchronization	893
Chapter 2. Logical Partitioning	
[Category:	
Embedded.Hypervisor].	895
2.1 Overview.	895
2.2 Registers	896
2.2.1 Register Mapping	896
2.2.2 Logical Partition Identification	
Register (LPIDR).	896
2.3 Interrupts and Exceptions.	896
2.3.1 Directed Interrupts.	896
2.3.2 Hypervisor Service Interrupts	897
2.4 Instruction Mapping	897
Chapter 3. Thread Control [Category:	
Embedded Multi-Threading]	899
3.1 Overview	899
3.2 Thread Identification Register	
(TIR)	899
3.3 Thread Enable Register (TEN)	899
3.4 Thread Enable Status Register	
(TENSR)	900
3.5 Disabling and Enabling Threads	900
3.6 Sharing of Multi-Threaded Processor	
Resources	900
3.7 Thread Management Facility	
[Category: Embedded	
Multithreading.Thread Management].	901
3.7.1 Initialize Next Instruction Address	
Registers	901
3.7.2 Thread Management	
Instructions	902
Chapter 4. Branch Facility	903
4.1 Branch Facility Overview.	903
4.2 Branch Facility Registers.	903
4.2.1 Machine State Register	903
4.2.2 Machine State Register Protect	
Register (MSRP)	905
4.2.3 Embedded Processor Control	
Register (EPCR)	906
4.3 Branch Facility Instructions	908
4.3.1 System Linkage Instructions	908
Chapter 5. Fixed-Point Facility.	913
5.1 Fixed-Point Facility Overview	913
5.2 Special Purpose Registers	913
5.3 Fixed-Point Facility Registers	913
5.3.1 Processor Version Register	913
5.3.2 Processor Identification	
Register	914
5.3.3 Guest Processor Identification	
Register [Category:	
Embedded.Hypervisor]	914
5.3.4 Program Priority Register 32-bit	
[Category: Phased-In]	914
5.3.5 Software-use SPRs	915
5.3.6 External Process ID Registers	
[Category: Embedded.External PID].	916
5.3.6.1 External Process ID Load Context	
(EPLC) Register	916
5.3.6.2 External Process ID Store Context	
(EPSC) Register	917
5.4 Fixed-Point Facility Instructions.	918
5.4.1 Move To/From System Register	
Instructions	918
5.4.2 OR Instruction	926
5.4.3 External Process ID Instructions	
[Category: Embedded.External PID].	927

Chapter 6. Storage Control 939

6.1 Overview	940
6.2 Storage Exceptions	942
6.3 Instruction Fetch	942
6.3.1 Implicit Branch.	942
6.3.2 Address Wrapping Combined with Changing MSR Bit CM.	943
6.4 Data Access.	943
6.5 Performing Operations Out-of-Order.	943
6.6 Invalid Real Address	944
6.7 Storage Control	944
6.7.1 Translation Lookaside Buffer.	944
6.7.2 Virtual Address Spaces.	949
6.7.3 TLB Address Translation.	950
6.7.4 Page Table Address Translation [Category: Embedded.Page Table].	953
6.7.5 Page Table Update Synchronization Requirements [Category: Embedded.Page Table]	961
6.7.5.1 Page Table Updates.	962
6.7.5.1.1 Adding a Page Table Entry	962
6.7.5.1.2 Deleting a Page Table Entry	963
6.7.5.1.3 Modifying a Page Table Entry	963
6.7.5.2 Invalidating an Indirect TLB Entry	963
6.7.6 Storage Access Control	964
6.7.6.1 Execute Access	964
6.7.6.2 Write Access	964
6.7.6.3 Read Access	965
6.7.6.4 Virtualized Access <E.HV>	965
6.7.6.5 Storage Access Control Applied to Cache Management Instructions	965
6.7.6.6 Storage Access Control Applied to String Instructions.	966
6.8 Storage Control Attributes	966
6.8.1 Guarded Storage.	966
6.8.1.1 Out-of-Order Accesses to Guarded Storage.	966
6.8.2 User-Definable	966
6.8.3 Storage Control Bits	966
6.8.3.1 Storage Control Bit Restrictions.	967
6.8.3.2 Altering the Storage Control Bits	968
6.9 Logical to Real Address Translation [Category: Embedded.Hypervisor.LRAT]	971
6.10 Storage Control Registers	973
6.10.1 Process ID Register	973
6.10.2 MMU Assist Registers.	973
6.10.3 MMU Configuration and Control Registers	974
6.10.3.1 MMU Configuration Register (MMUCFG).	974
6.10.3.2 TLB Configuration Registers (TLBnCFG)	974
6.10.3.3 TLB Page Size Registers (TLBnPS) [MAV=2.0].	976
6.10.3.4 Embedded Page Table Configuration Register (EPTCFG)	976
6.10.3.5 LRAT Configuration Register (LRATCFG) [Category: Embedded.Hypervisor.LRAT]	977
6.10.3.6 LRAT Page Size Register (LRATPS) [Category: Embedded.Hypervisor.LRAT]	977
6.10.3.7 MMU Control and Status Register (MMUCSR0)	978
6.10.3.8 MAS0 Register	978
6.10.3.9 MAS1 Register	980
6.10.3.10 MAS2 Register	980
6.10.3.11 MAS3 Register	981
6.10.3.12 MAS4 Register	982
6.10.3.13 MAS5 Register [Category: Embedded.Hypervisor]	983
6.10.3.14 MAS6 Register	983
6.10.3.15 MAS7 Register	984
6.10.3.16 MAS8 Register [Category: Embedded.Hypervisor]	984
6.10.3.17 Accesses to Paired MAS Registers.	985
6.10.3.18 MAS Register Update Summary 985	
6.11 Storage Control Instructions	988
6.11.1 Cache Management Instructions.	988
6.11.2 Cache Locking [Category: Embedded.Cache Locking].	989
6.11.2.1 Lock Setting and Clearing	989
6.11.2.2 Error Conditions	989
6.11.2.2.1 Overlocking	990
6.11.2.2.2 Unable-to-lock and Unable-to- unlock Conditions	990
6.11.2.3 Cache Locking Instructions	991
6.11.3 Synchronize Instruction	993
6.11.4 LRAT [Category: Embedded.Hypervisor.LRAT] and TLB Management.	993
6.11.4.1 Reading TLB or LRAT Entries	993
6.11.4.2 Writing TLB or LRAT Entries.	993
6.11.4.2.1 TLB Write Conditional [Embedded.TLB Write Conditional].	994
6.11.4.3 Invalidating TLB Entries	997
6.11.4.4 TLB Lookaside Information.	999
6.11.4.5 Invalidating LRAT Entries	999
6.11.4.6 Searching TLB Entries	999
6.11.4.7 TLB Replacement Hardware Assist	999
6.11.4.8 32-bit and 64-bit Specific MMU Behavior	1000

6.11.4.9	TLB Management Instructions . . .	1001
----------	-----------------------------------	------

Chapter 7. Interrupts and

Exceptions 1013

7.1	Overview	1014
7.2	Interrupt Registers	1014
7.2.1	Save/Restore Register 0	1014
7.2.2	Save/Restore Register 1	1015
7.2.3	Guest Save/Restore Register 0 [Category:Embedded.Hypervisor]. . .	1015
7.2.4	Guest Save/Restore Register 1 [Category:Embedded.Hypervisor]. . .	1015
7.2.5	Critical Save/Restore Register 0 . . .	1016
7.2.6	Critical Save/Restore Register 1 . . .	1016
7.2.7	Debug Save/Restore Register 0 [Category: Embedded.Enhanced Debug].	1016
7.2.8	Debug Save/Restore Register 1 [Category: Embedded.Enhanced Debug].	1017
7.2.9	Data Exception Address Register . .	1017
7.2.10	Guest Data Exception Address Register [Category: Embedded.Hypervisor].	1017
7.2.11	Interrupt Vector Prefix Register . . .	1018
7.2.12	Guest Interrupt Vector Prefix Register [Category: Embedded.Hypervisor.Phased-Out].	1018
7.2.13	Exception Syndrome Register	1019
7.2.14	Guest Exception Syndrome Register [Category: Embedded.Hypervisor].	1020
7.2.15	Interrupt Vector Offset Registers [Category: Embedded.Phased-Out] .	1020
7.2.16	Guest Interrupt Vector Offset Register [Category: Embedded.Hypervisor.Phased-Out] .	1021
7.2.17	Logical Page Exception Register [Category: Embedded.Hypervisor and Embedded.Page Table].	1022
7.2.18	Machine Check Registers . . .	1022
7.2.18.1	Machine Check Save/Restore Register 0	1022
7.2.18.2	Machine Check Save/Restore Register 1	1022
7.2.18.3	Machine Check Syndrome Register.	1023
7.2.18.4	Machine Check Interrupt Vector Prefix Register	1023
7.2.19	External Proxy Register [Category: External Proxy]	1023

7.2.20	Guest External Proxy Register [Category: Embedded Hypervisor, External Proxy].	1023
7.3	Exceptions.	1025
7.4	Interrupt Classification.	1025
7.4.1	Asynchronous Interrupts	1025
7.4.2	Synchronous Interrupts	1025
7.4.2.1	Synchronous, Precise Interrupts . .	1026
7.4.2.2	Synchronous, Imprecise Interrupts	1026
7.4.3	Interrupt Classes	1026
7.4.4	Machine Check Interrupts	1026
7.5	Interrupt Processing	1027
7.6	Interrupt Definitions.	1030
7.6.1	Interrupt Fixed Offsets [Category: Embedded.Phased-In].	1033
7.6.2	Critical Input Interrupt.	1034
7.6.3	Machine Check Interrupt	1034
7.6.4	Data Storage Interrupt	1035
7.6.5	Instruction Storage Interrupt. . .	1037
7.6.6	External Input Interrupt	1039
7.6.7	Alignment Interrupt.	1039
7.6.8	Program Interrupt.	1040
7.6.9	Floating-Point Unavailable Interrupt .	1042
7.6.10	System Call Interrupt	1042
7.6.11	Auxiliary Processor Unavailable Interrupt.	1042
7.6.12	Decrementer Interrupt	1043
7.6.13	Fixed-Interval Timer Interrupt.	1043
7.6.14	Watchdog Timer Interrupt.	1044
7.6.15	Data TLB Error Interrupt.	1044
7.6.16	Instruction TLB Error Interrupt	1045
7.6.17	Debug Interrupt	1046
7.6.18	SPE/Embedded Floating-Point/ Vector Unavailable Interrupt [Categories: SPE.Embedded Float Scalar Double, SPE.Embedded Float Vector, Vector]	1047
7.6.19	Embedded Floating-Point Data Interrupt [Categories: SPE.Embedded Float Scalar Double, SPE.Embedded Float Scalar Single, SPE.Embedded Float Vector]	1048
7.6.20	Embedded Floating-Point Round Interrupt [Categories: SPE.Embedded Float Scalar Double, SPE.Embedded Float Scalar Single, SPE.Embedded Float Vector]	1048
7.6.21	Performance Monitor Interrupt [Category: Embedded.Performance Monitor]	1049
7.6.22	Processor Doorbell Interrupt [Category: Embedded.Processor Control]	1049

7.6.23	Processor Doorbell Critical Interrupt [Category: Embedded.Processor Control].	1049
7.6.24	Guest Processor Doorbell Interrupt [Category: Embedded.Hypervisor,Embedded.Processor Control].	1049
7.6.25	Guest Processor Doorbell Critical Interrupt [Category: Embedded.Hypervisor,Embedded.Processor Control].	1051
7.6.26	Guest Processor Doorbell Machine Check Interrupt [Category: Embedded.Hypervisor,Embedded.Processor Control].	1051
7.6.27	Embedded Hypervisor System Call Interrupt [Category: Embedded.Hypervisor].	1051
7.6.28	Embedded Hypervisor Privilege Interrupt [Category: Embedded.Hypervisor].	1052
7.6.29	LRAT Error Interrupt [Category: Embedded.Hypervisor.LRAT].	1052
7.7	Partially Executed Instructions . . .	1054
7.8	Interrupt Ordering and Masking . .	1055
7.8.1	Guidelines for System Software	1056
7.8.2	Interrupt Order	1058
7.9	Exception Priorities	1059
7.9.1	Exception Priorities for Defined Instructions	1059
7.9.1.1	Exception Priorities for Defined Floating-Point Load and Store Instructions	1059
7.9.1.2	Exception Priorities for Other Defined Load and Store Instructions and Defined Cache Management Instructions . .	1059
7.9.1.3	Exception Priorities for Other Defined Floating-Point Instructions. . .	1060
7.9.1.4	Exception Priorities for Defined Privileged Instructions	1060
7.9.1.5	Exception Priorities for Defined Trap Instructions	1060
7.9.1.6	Exception Priorities for Defined System Call Instruction.	1060
7.9.1.7	Exception Priorities for Defined Branch Instructions.	1060
7.9.1.8	Exception Priorities for Defined Return From Interrupt Instructions . . .	1061
7.9.1.9	Exception Priorities for Other Defined Instructions	1061
7.9.2	Exception Priorities for Reserved Instructions	1061

Chapter 8. Reset and Initialization . . 1063

8.1	Background.	1063
8.2	Reset Mechanisms	1063
8.3	Thread State after Reset	1063
8.4	Software Initialization Requirements	1065

Chapter 9. Timer Facilities 1067

9.1	Overview.	1067
9.2	Time Base (TB)	1067
9.2.1	Writing the Time Base	1068
9.3	Decrementer.	1069
9.3.1	Writing and Reading the Decrementer	1069
9.3.2	Decrementer Events	1069
9.4	Decrementer Auto-Reload Register . . 1070	
9.5	Timer Control Register	1070
9.5.1	Timer Status Register	1072
9.6	Fixed-Interval Timer	1073
9.7	Watchdog Timer	1073
9.8	Freezing the Timer Facilities	1075

Chapter 10. Debug Facilities . . 1077

10.1	Overview.	1077
10.2	Internal Debug Mode	1077
10.3	External Debug Mode [Category: Embedded.Enhanced Debug].	1078
10.4	Debug Events	1078
10.4.1	Instruction Address Compare Debug Event	1079
10.4.2	Data Address Compare Debug Event.	1081
10.4.3	Trap Debug Event	1082
10.4.4	Branch Taken Debug Event . .	1083
10.4.5	Instruction Complete Debug Event 1083	
10.4.6	Interrupt Taken Debug Event . 1083	
10.4.6.1	Causes of Interrupt Taken Debug Events	1083
10.4.6.2	Interrupt Taken Debug Event Description	1083
10.4.7	Return Debug Event	1084
10.4.8	Unconditional Debug Event . .	1084
10.4.9	Critical Interrupt Taken Debug Event [Category: Embedded.Enhanced Debug].	1084
10.4.10	Critical Interrupt Return Debug Event [Category: Embedded.Enhanced Debug].	1085
10.5	Debug Registers.	1085
10.5.1	Debug Control Registers	1085
10.5.1.1	Debug Control Register 0 (DBCRO)	1085

10.5.1.2	Debug Control Register 1 (DBCR1)	1087	A.2.1.3	Instruction Cache Debug Data Register	1105
10.5.1.3	Debug Control Register 2 (DBCR2)	1088	A.2.1.4	Instruction Cache Debug Tag Register High	1105
10.5.2	Debug Status Register	1089	A.2.1.5	Instruction Cache Debug Tag Register Low	1105
10.5.3	Debug Status Register Write Register (DBSRWR)	1091	A.2.2	Embedded Cache Debug Instructions	1106
10.5.4	Instruction Address Compare Registers	1091			
10.5.5	Data Address Compare Registers	1091	Appendix B. Assembler Extended Mnemonics	1109	
10.5.6	Data Value Compare Registers	1091	B.1	Move To/From Special Purpose Register Mnemonics	1110
10.6	Debugger Notify Halt Instruction [Category: Embedded.Enhanced Debug]	1092	Appendix C. Guidelines for 64-bit Implementations in 32-bit Mode and 32-bit Implementations	1111	
Chapter 11. Processor Control [Category: Embedded.Processor Control]	1093		C.1	Hardware Guidelines	1111
11.1	Overview	1093	C.1.1	64-bit Specific Instructions	1111
11.2	Programming Model	1093	C.1.2	Registers on 32-bit Implementations	1111
11.2.1	Message Handling and Filtering	1093	C.1.3	Addressing on 32-bit Implementations	1111
11.2.2	Doorbell Message Filtering	1094	C.1.4	TLB Fields on 32-bit Implementations	1111
11.2.2.1	Doorbell Critical Message Filtering	1095	C.2	32-bit Software Guidelines	1111
11.2.2.2	Guest Doorbell Message Filtering [Category: Embedded.Hypervisor]	1095	C.2.1	32-bit Instruction Selection	1111
11.2.2.3	Guest Doorbell Critical Message Filtering [Category: Embedded.Hypervisor]	1096	Appendix D. Example Performance Monitor [Category: Embedded.Performance Monitor]	1113	
11.2.2.4	Guest Doorbell Machine Check Message Filtering [Category: Embedded.Hypervisor]	1096	D.1	Overview	1113
11.3	Processor Control Instructions	1098	D.2	Programming Model	1113
			D.2.1	Event Counting	1114
			D.2.2	Thread Context Configurability	1114
			D.2.3	Event Selection	1115
			D.2.4	Thresholds	1115
			D.2.5	Performance Monitor Exception	1115
			D.2.6	Performance Monitor Interrupt	1115
			D.3	Performance Monitor Registers	1115
			D.3.1	Performance Monitor Global Control Register 0	1115
			D.3.2	Performance Monitor Local Control A Registers	1116
			D.3.3	Performance Monitor Local Control B Registers	1116
			D.3.4	Performance Monitor Counter Registers	1117
			D.4	Performance Monitor Instructions	1118
			D.5	Performance Monitor Software Usage Notes	1119
			D.5.1	Chaining Counters	1119
			D.5.2	Thresholding	1119
Chapter 12. Synchronization Requirements for Context Alterations	1099				
Appendix A. Implementation-Dependent Instructions	1103				
A.1	Embedded Cache Initialization [Category: Embedded.Cache Initialization]	1103			
A.2	Embedded Cache Debug Facility [Category: Embedded.Cache Debug]	1104			
A.2.1	Embedded Cache Debug Registers	1104			
A.2.1.1	Data Cache Debug Tag Register High	1104			
A.2.1.2	Data Cache Debug Tag Register Low	1104			

Book VLE:

**Power ISA Operating Environment
Architecture - Variable Length
Encoding (VLE) Environment
[Category: Variable Length
Encoding]..... 1121**

**Chapter 1. Variable Length Encoding
Introduction 1123**

- 1.1 Overview1123
- 1.2 Documentation Conventions ... 1124
 - 1.2.1 Description of Instruction
Operation1124
- 1.3 Instruction Mnemonics and
Operands1124
- 1.4 VLE Instruction Formats.....1124
 - 1.4.1 BD8-form (16-bit Branch
Instructions)1124
 - 1.4.2 C-form (16-bit Control
Instructions)1124
 - 1.4.3 IM5-form (16-bit register + immediate
Instructions)1124
 - 1.4.4 OIM5-form (16-bit register + offset
immediate Instructions)1124
 - 1.4.5 IM7-form (16-bit Load immediate
Instructions)1124
 - 1.4.6 R-form (16-bit Monadic
Instructions)1125
 - 1.4.7 RR-form (16-bit Dyadic
Instructions)1125
 - 1.4.8 SD4-form (16-bit Load/Store
Instructions)1125
 - 1.4.9 BD15-form.....1125
 - 1.4.10 BD24-form.....1125
 - 1.4.11 D8-form.....1125
 - 1.4.12 ESC-form1125
 - 1.4.13 I16A-form1125
 - 1.4.14 I16L-form.....1125
 - 1.4.15 M-form.....1125
 - 1.4.16 SCI8-form1125
 - 1.4.17 LI20-form.....1125
 - 1.4.18 X-form1126
 - 1.4.19 Instruction Fields.....1126

**Chapter 2. VLE Storage
Addressing..... 1129**

- 2.1 Data Storage Addressing
Modes.....1129
- 2.2 Instruction Storage Addressing
Modes.....1130

- 2.2.1 Misaligned, Mismatched, and Byte
Ordering Instruction Storage
Exceptions 1130
- 2.2.2 VLE Exception Syndrome Bits. 1130

**Chapter 3. VLE Compatibility with
Books I–III 1133**

- 3.1 Overview..... 1133
- 3.2 VLE Processor and Storage Control
Extensions 1133
 - 3.2.1 Instruction Extensions 1133
 - 3.2.2 MMU Extensions 1133
- 3.3 VLE Limitations..... 1134

**Chapter 4. Branch Operation
Instructions..... 1135**

- 4.1 Branch Facility Registers 1135
 - 4.1.1 Condition Register (CR) 1135
 - 4.1.1.1 Condition Register Setting for
Compare Instructions 1136
 - 4.1.1.2 Condition Register Setting for the
Bit Test Instruction..... 1136
 - 4.1.2 Link Register (LR) 1136
 - 4.1.3 Count Register (CTR) 1136
- 4.2 Branch Instructions..... 1137
- 4.3 System Linkage Instructions... 1140
- 4.4 Condition Register Instructions.. 1144

**Chapter 5. Fixed-Point
Instructions..... 1147**

- 5.1 Fixed-Point Load Instructions ... 1147
- 5.2 Fixed-Point Store Instructions... 1151
- 5.3 Fixed-Point Load and Store with Byte
Reversal Instructions..... 1154
- 5.4 Fixed-Point Load and Store Multiple
Instructions 1154
- 5.5 Fixed-Point Arithmetic
Instructions 1155
- 5.6 Fixed-Point Compare and Bit Test
Instructions 1159
- 5.7 Fixed-Point Trap Instructions ... 1163
- 5.8 Fixed-Point Select Instruction... 1163
- 5.9 Fixed-Point Logical, Bit, and Move
Instructions 1164
- 5.10 Fixed-Point Rotate and Shift
Instructions 1169
- 5.11 Move To/From System Register
Instructions 1172

**Chapter 6. Storage Control
Instructions..... 1173**

- 6.1 Storage Synchronization
Instructions..... 1173
- 6.2 Cache Management Instructions 1174

6.3	Cache Locking Instructions	1174
6.4	TLB Management Instructions	1174
6.5	Instruction Alignment and Byte Ordering	1174

Chapter 7. Additional Categories

Available in VLE 1175

7.1	Move Assist	1175
7.2	Vector	1175
7.3	Signal Processing Engine	1175
7.4	Embedded Floating Point	1175
7.5	Embedded Hypervisor	1175
7.6	Legacy Move Assist	1175
7.7	External PID	1176
7.8	Embedded Performance Monitor	1176
7.9	Processor Control	1176
7.10	Decorated Storage	1176
7.11	Embedded Cache Initialization	1176
7.12	Embedded Cache Debug	1176

Appendix A. VLE Instruction Set Sorted by Mnemonic 1177

Appendix B. VLE Instruction Set Sorted by Opcode 1193

Appendices:

Power ISA Book I-III Appendices 1209

Appendix A. Incompatibilities with the POWER Architecture 1211

A.1	New Instructions, Formerly Privileged Instructions	1211
A.2	Newly Privileged Instructions	1211
A.3	Reserved Fields in Instructions	1211
A.4	Reserved Bits in Registers	1211
A.5	Alignment Check	1211
A.6	Condition Register	1212
A.7	LK and Rc Bits	1212
A.8	BO Field	1212
A.9	BH Field	1212
A.10	Branch Conditional to Count Register	1212
A.11	System Call	1212
A.12	Fixed-Point Exception Register (XER)	1213
A.13	Update Forms of Storage Access Instructions	1213
A.14	Multiple Register Loads	1213

A.15	Load/Store Multiple Instructions	1213
A.16	Move Assist Instructions	1213
A.17	Move To/From SPR	1213
A.18	Effects of Exceptions on FPSCR Bits FR and FI	1214
A.19	Store Floating-Point Single Instructions	1214
A.20	Move From FPSCR	1214
A.21	Zeroing Bytes in the Data Cache	1214
A.22	Synchronization	1214
A.23	Move To Machine State Register Instruction	1215
A.24	Direct-Store Segments	1215
A.25	Segment Register Manipulation Instructions	1215
A.26	TLB Entry Invalidation	1215
A.27	Alignment Interrupts	1215
A.28	Floating-Point Interrupts	1215
A.29	Timing Facilities	1215
A.29.1	Real-Time Clock	1215
A.29.2	Decrementer	1216
A.30	Deleted Instructions	1216
A.31	Discontinued Opcodes	1216
A.32	POWER2 Compatibility	1218
A.32.1	Cross-Reference for Changed POWER2 Mnemonics	1218
A.32.2	Load/Store Floating-Point Double	1218
A.32.3	Floating-Point Conversion to Integer	1218
A.32.4	Floating-Point Interrupts	1219
A.32.5	Trace	1219

1.1 Overview

This chapter describes computation modes, document conventions, a processor overview, instruction formats, storage addressing, and instruction fetching.

1.2 Instruction Mnemonics and Operands

The description of each instruction includes the mnemonic and a formatted list of operands. Some examples are the following.

stw	RS,D(RA)
addis	RT,RA,SI

Power ISA-compliant Assemblers will support the mnemonics and operand lists exactly as shown. They should also provide certain extended mnemonics, such as the ones described in Appendix E of Book I.

1.3 Document Conventions

1.3.1 Definitions

The following definitions are used throughout this document.

- **program**
A sequence of related instructions.
- **application program**
A program that uses only the instructions and resources described in Books I and II.
- **Processor**
The hardware component that implements the instruction set, storage model, and other facilities defined in the Power ISA architecture, and executes the instructions specified in a program.
- **quadwords, doublewords, words, halfwords, and bytes**
128 bits, 64 bits, 32 bits, 16 bits, and 8 bits, respectively.
- **positive**
Means greater than zero.
- **negative**
Means less than zero.
- **floating-point single format** (or simply **single format**)
Refers to the representation of a single-precision binary floating-point value in a register or storage.
- **floating-point double format** (or simply **double format**)
Refers to the representation of a double-precision binary floating-point value in a register or storage.
- **system library program**
A component of the system software that can be called by an application program using a *Branch* instruction.
- **system service program**
A component of the system software that can be called by an application program using a *System Call* instruction.
- **system trap handler**
A component of the system software that receives control when the conditions specified in a *Trap* instruction are satisfied.
- **system error handler**
A component of the system software that receives control when an error occurs. The system error

handler includes a component for each of the various kinds of error. These error-specific components are referred to as the system alignment error handler, the system data storage error handler, etc.

- **latency**
Refers to the interval from the time an instruction begins execution until it produces a result that is available for use by a subsequent instruction.
- **unavailable**
Refers to a resource that cannot be used by the program. For example, storage is unavailable if access to it is denied. See Book III.
- **undefined value**
May vary between implementations, and between different executions on the same implementation, and similarly for register contents, storage contents, etc., that are specified as being undefined.
- **boundedly undefined**
The results of executing a given instruction are said to be boundedly undefined if they could have been achieved by executing an arbitrary finite sequence of instructions (none of which yields boundedly undefined results) in the state the processor was in before executing the given instruction. Boundedly undefined results may include the presentation of inconsistent state to the system error handler as described in Section 1.8.1 of Book II. Boundedly undefined results for a given instruction may vary between implementations, and between different executions on the same implementation.
- **“must”**
If software violates a rule that is stated using the word “must” (e.g., “this field must be set to 0”), the results are boundedly undefined unless otherwise stated.
- **sequential execution model**
The model of program execution described in Section 2.2, “Instruction Execution Order” on page 29.
- **Auxiliary Processor**
An implementation-specific processing unit. Previous versions of the architecture use the term Auxiliary Processing Unit (APU) to describe this extension of the architecture. Architectural support for auxiliary processors is part of the Embedded category.

1.3.2 Notation

The following notation is used throughout the Power ISA documents.

- All numbers are decimal unless specified in some special way.

- 0bnnnn means a number expressed in binary format.
- 0xnxxx means a number expressed in hexadecimal format.

Underscores may be used between digits.

- RT, RA, R1, ... refer to General Purpose Registers.
- FRT, FRA, FR1, ... refer to Floating-Point Registers.
- FRTp, FRAp, FRBp, ... refer to an even-odd pair of Floating-Point Registers. Values must be even, otherwise the instruction form is invalid.
- VRT, VRA, VR1, ... refer to Vector Registers.
- (x) means the contents of register x, where x is the name of an instruction field. For example, (RA) means the contents of register RA, and (FRA) means the contents of register FRA, where RA and FRA are instruction fields. Names such as LR and CTR denote registers, not fields, so parentheses are not used with them. Parentheses are also omitted when register x is the register into which the result of an operation is placed.
- (RAI0) means the contents of register RA if the RA field has the value 1-31, or the value 0 if the RA field is 0.
- Bytes in instructions, fields, and bit strings are numbered from left to right, starting with byte 0 (most significant).
- Bits in registers, instructions, fields, and bit strings are specified as follows. In the last three items (definition of X_p etc.), if X is a field that specifies a GPR, FPR, or VR (e.g., the RS field of an instruction), the definitions apply to the register, not to the field.
 - Bits in instructions, fields, and bit strings are numbered from left to right, starting with bit 0
 - For all registers except the Vector category, bits in registers that are less than 64 bits start with bit number 64-L, where L is the register length; for the Vector category, bits in registers that are less than 128 bits start with bit number 128-L.
 - The leftmost bit of a sequence of bits is the most significant bit of the sequence.
 - X_p means bit p of register/instruction/field/bit_string X.
 - $X_{p:q}$ means bits p through q of register/instruction/field/bit_string X.
 - $X_{p\ q\ \dots}$ means bits p, q, ... of register/instruction/field/bit_string X.
- \neg (RA) means the one's complement of the contents of register RA.
- A period (.) as the last character of an instruction mnemonic means that the instruction records sta-

tus information in certain fields of the Condition Register as a side effect of execution.

- The symbol || is used to describe the concatenation of two values. For example, 010 || 111 is the same as 010111.
- x^n means x raised to the n^{th} power.
- $^n x$ means the replication of x, n times (i.e., x concatenated to itself n-1 times). (n)0 and (n)1 are special cases:
 - $^n 0$ means a field of n bits with each bit equal to 0. Thus $^5 0$ is equivalent to 0b00000.
 - $^n 1$ means a field of n bits with each bit equal to 1. Thus $^5 1$ is equivalent to 0b11111.
- Each bit and field in instructions, and in status and control registers (e.g., XER, FPSCR) and Special Purpose Registers, is either defined or reserved. Some defined fields contain reserved values. In such cases when this document refers to the specific field, it refers only to the defined values, unless otherwise specified.
- /, //, ///, ... denotes a reserved field, in a register, instruction, field, or bit string.
- ?, ??, ???, ... denotes an implementation-dependent field in a register, instruction, field or bit string.

1.3.3 Reserved Fields and Reserved Values

Reserved fields in instructions are ignored by the processor. This is a requirement in the Server environment and is being phased into the Embedded environment.

In some cases a defined field of an instruction has certain values that are reserved. This includes cases in which the field is shown in the instruction layout as containing a particular value; in such cases all other values of the field are reserved. In general, if an instruction is coded such that a defined field contains a reserved value the instruction form is invalid; see Section 1.8.2 on page 23. The only exceptions to the preceding rule is that it does not apply to Reserved and Illegal classes of instructions (see Section 1.7) or to portions of defined fields that are specified, in the instruction description, as being treated as reserved fields.

To maximize compatibility with future architecture extensions, software must ensure that reserved fields in instructions contain zero and that defined fields of instructions do not contain reserved values.

The handling of reserved bits in System Registers (e.g., XER, FPSCR) is implementation-dependent. Unless otherwise stated, software is permitted to write any value to such a bit. A subsequent reading of the bit returns 0 if the value last written to the bit was 0 and returns an undefined value (0 or 1) otherwise.

In some cases a defined field of a System Register has certain values that are reserved. Software must not set a defined field of a System Register to a reserved value.

References elsewhere in this document to a defined field (in an instruction or System Register) that has reserved values assume the field does not contain a reserved value, unless otherwise stated or obvious from context.

Assembler Note

Assemblers should report uses of reserved values of defined fields of instructions as errors.

Programming Note

It is the responsibility of software to preserve bits that are now reserved in System Registers, because they may be assigned a meaning in some future version of the architecture.

In order to accomplish this preservation in implementation-independent fashion, software should do the following.

- Initialize each such register supplying zeros for all reserved bits.
- Alter (defined) bit(s) in the register by reading the register, altering only the desired bit(s), and then writing the new value back to the register.

The XER and FPSCR are partial exceptions to this recommendation. Software can alter the status bits in these registers, preserving the reserved bits, by executing instructions that have the side effect of altering the status bits. Similarly, software can alter any defined bit in the FPSCR by executing a Floating-Point Status and Control Register instruction. Using such instructions is likely to yield better performance than using the method described in the second item above.

1.3.4 Description of Instruction Operation

Instruction descriptions (including related material such as the introduction to the section describing the instructions) mention that the instruction may cause a system error handler to be invoked, under certain conditions, if and only if the system error handler may treat the case as a programming error. (An instruction may cause a system error handler to be invoked under other conditions as well; see Chapter 6 of Book III-S and Chapter 7 of Book III-E).

A formal description is given of the operation of each instruction. In addition, the operation of most instructions is described by a semiformal language at the register transfer level (RTL). This RTL uses the notation given below, in addition to the notation described in Section 1.3.2. Some of this notation is also used in the formal descriptions of instructions. RTL notation not summarized here should be self-explanatory.

The RTL descriptions cover the normal execution of the instruction, except that “standard” setting of status registers, such as the Condition Register, is not shown. (“Non-standard” setting of these registers, such as the setting of the Condition Register by the *Compare* instructions, is shown.) The RTL descriptions do not cover cases in which the system error handler is invoked, or for which the results are boundedly undefined.

The RTL descriptions specify the architectural transformation performed by the execution of an instruction. They do not imply any particular implementation.

Notation Meaning

\leftarrow	Assignment
\leftarrow_{iea}	Assignment of an instruction effective address. In 32-bit mode the high-order 32 bits of the 64-bit target address are set to 0.
\neg	NOT logical operator
$+$	Two's complement addition
$-$	Two's complement subtraction, unary minus
\times	Multiplication
\times_{si}	Signed-integer multiplication
\times_{ui}	Unsigned-integer multiplication
$/$	Division
\div	Division, with result truncated to integer
$\sqrt{\quad}$	Square root
$=, \neq$	Equals, Not Equals relations
$<, \leq, >, \geq$	Signed comparison relations
$<^u, >^u$	Unsigned comparison relations
$?$	Unordered comparison relation
$\&, $	AND, OR logical operators
\oplus, \equiv	Exclusive OR, Equivalence logical operators ($(a \equiv b) = (a \oplus b)$)
$ABS(x)$	Absolute value of x
$CEIL(x)$	Least integer $\geq x$
$DCR(x)$	Device Control Register $x <E.DC>$
$DOUBLE(x)$	Result of converting x from floating-point single format to floating-point double format, using the model shown on page 123
$EXTS(x)$	Result of extending x on the left with sign bits
$FLOOR(x)$	Greatest integer $\leq x$
$GPR(x)$	General Purpose Register x
$MASK(x, y)$	Mask having 1s in positions x through y (wrapping if $x > y$) and 0s elsewhere
$MEM(x, y)$	Contents of a sequence of y bytes of storage. The sequence depends on the byte ordering used for storage access, as follows. Big-Endian byte ordering: The sequence starts with the byte at address x and ends with the byte at address $x+y-1$. Little-Endian byte ordering: The sequence starts with the byte at address $x+y-1$ and ends with the byte at address x .
$MEM_DECORATED(x,y,z)$	Contents of a sequence of y bytes of storage, where the storage is accessed with decoration z applied. The sequence depends on the byte ordering used for storage access, as follows. Big-Endian byte ordering: The sequence starts with the byte at address x and ends with the byte at address $x+y-1$.

Little-Endian byte ordering:

The sequence starts with the byte at address $x+y-1$ and ends with the byte at address x .

$MEM_NOTIFY(x,z)$

The decoration z is sent to storage location x .

$ROTL_{64}(x, y)$

Result of rotating the 64-bit value x left y positions

$ROTL_{32}(x, y)$

Result of rotating the 64-bit value x left y positions, where x is 32 bits long

$SINGLE(x)$

Result of converting x from floating-point double format to floating-point single format, using the model shown on page 127

$SPR(x)$

Special Purpose Register x

$TRAP$

Invoke the system trap handler

characterization

Reference to the setting of status bits, in a standard way that is explained in the text

undefined

An undefined value.

CIA

Current Instruction Address, which is the 64-bit address of the instruction being described by a sequence of RTL. Used by relative branches to set the Next Instruction Address (NIA), and by Branch instructions with $LK=1$ to set the Link Register. Does not correspond to any architected register.

NIA

Next Instruction Address, which is the 64-bit address of the next instruction to be executed. For a successful branch, the next instruction address is the branch target address: in RTL, this is indicated by assigning a value to NIA . For other instructions that cause non-sequential instruction fetching (see Book III), the RTL is similar. For instructions that do not branch, and do not otherwise cause instruction fetching to be non-sequential, the next instruction address is $CIA+4$ (VLE behavior is different; see Book VLE). Does not correspond to any architected register.

if... then... else...

Conditional execution, indenting shows range; else is optional.

do

Do loop, indenting shows range. "To" and/or "by" clauses specify incrementing an iteration variable, and a "while" clause gives termination conditions.

leave

Leave innermost do loop, or do loop described in leave statement.

for

For loop, indenting shows range. Clause after "for" specifies the entities for which to execute the body of the loop.

The precedence rules for RTL operators are summarized in Table 1. Operators higher in the table are applied before those lower in the table. Operators at the same level in the table associate from left to right, from right to left, or not at all, as shown. (For example, $-$ associates from left to right, so $a-b-c = (a-b)-c$.) Parentheses are used to override the evaluation order implied by the table or to increase clarity; parenthesized expressions are evaluated before serving as operands.

Operators	Associativity
subscript, function evaluation	left to right
pre-superscript (replication), post-superscript (exponentiation)	<i>right to left</i>
unary $-$, \neg	<i>right to left</i>
\times , \div	left to right
$+$, $-$	left to right
\parallel	left to right
$=$, \neq , $<$, \leq , $>$, \geq , $<^u$, $>^u$, $?$	left to right

Operators	Associativity
$\&$, \oplus , \equiv	left to right
$ $	left to right
$:$ (range)	none
\leftarrow , \leftarrow_{iea}	none

1.3.5 Categories

Each facility (including registers and fields therein) and instruction is in exactly one of the categories listed in Figure 1.

A category may be defined as a *dependent category*. These are categories that are supported only if the category they are dependent on is also supported. Dependent categories are identified by the “.” in their category name, e.g., if an implementation supports the Floating-Point.Record category, then the Floating-Point category is also supported.

An implementation that supports a facility or instruction in a given category, except for the two categories

Category	Abvr.	Notes
Base	B	Required for all implementations
Server	S	Required for Server implementations
Embedded	E	Required for Embedded implementations
Alternate Time Base	ATB	An additional Time Base; see Book II
Cache Specification	CS	Specify a specific cache for some instructions; see Book II
Decimal Floating-Point	DFP	Decimal Floating-Point facilities
Decorated Storage	DS	Decorated Storage facilities
Embedded.Cache Debug	E.CD	Provides direct access to cache data and directory content
Embedded.Cache Initialization	E.CI	Instructions that invalidate the entire cache
Embedded.Device Control	E.DC	Legacy Device Control bus support
Embedded.Enhanced Debug	E.ED	Embedded Enhanced Debug facility; see Book III-E
Embedded.External PID	E.PD	Embedded External PID facility; see Book III-E
Embedded.Hypervisor Embedded.Hypervisor.LRAT	E.HV E.HV.LRAT	Embedded Logical Partitioning and hypervisor facilities Embedded Hypervisor Logical to Real Address Translation facility; see Book III-E
Embedded.Little-Endian	E.LE	Embedded Little-Endian page attribute; see Book III-E
Embedded.Page Table	E.PT	Embedded Page Table facility; see Book III-E
Embedded.TLB Write Conditional	E.TWC	Embedded TLB Write Conditional facility; see Book III-E
Embedded.Performance Monitor	E.PM	Embedded Performance Monitor example; see Book III-E
Embedded.Processor Control	E.PC	Embedded Processor Control facility; see Book III-E
Embedded Cache Locking	ECL	Embedded Cache Locking facility; see Book III-E
Embedded Multi-Threading Embedded Multi-Threading.Thread Management	EM EM.TM	Embedded Multi-Threading; see Book III-E Embedded Multi-Threading Thread Management Facility
External Control	EC	External Control facility; see Book II

Figure 1. Category Listing (Sheet 1 of 2)

Category	Abvr.	Notes
External Proxy	EXP	External Proxy facility; see Book III-E
Floating-Point	FP	Floating-Point Facilities
Floating-Point.Record	FP.R	Floating-Point instructions with Rc=1
Legacy Integer Multiply-Accumulate ¹	LMA	<i>Legacy Integer Multiply-accumulate</i> instructions
Legacy Move Assist	LMV	<i>Determine Left most Zero Byte</i> instruction
Load/Store Quadword	LSQ	<i>Load/Store Quadword</i> instructions; see Book III-S
Memory Coherence	MMC	Requirement for Memory Coherence; see Book II
Move Assist	MA	<i>Move Assist</i> instructions
Processor Compatibility	PCR	Processor Compatibility Register
Server.Performance Monitor	S.PM	Server Performance Monitor example; see Book III-S
Server.Relaxed Page Table Alignment	S.RPTA	HTAB alignment on 256 KB boundary; see Book III-S
Signal Processing Engine ^{1, 2}	SP	Facility for signal processing
SPE.Embedded Float Scalar Double	SP.FD	GPR-based Floating-Point double-precision instruction set
SPE.Embedded Float Scalar Single	SP.FS	GPR-based Floating-Point single-precision instruction set
SPE.Embedded Float Vector	SP.FV	GPR-based Floating-Point Vector instruction set
Store Conditional Page Mobility	SCPM	<i>Store Conditional</i> accounting for page movement; see Book II
Stream	STM	Stream variant of <i>dcbt</i> instruction; see Book II
Strong Access Order	SAO	Assist for X86 and Sparc emulation; see Book II
Trace	TRC	Trace Facility; see Book III-S
Variable Length Encoding	VLE	Variable Length Encoding facility; see Book VLE
Vector-Scalar Extension	VSX	Vector-Scalar Extension Requires implementation of Floating-Point and Vector categories
Vector ¹	V	Vector facilities
Vector.Little-Endian	V.LE	Little-Endian support for Vector storage operations.
Wait	WT	<i>wait</i> instruction; see Book II
64-Bit	64	Required for 64-bit implementations; not defined for 32-bit impl's
¹ Because of overlapping opcode usage, SPE is mutually exclusive with Vector and with Legacy Integer Multiply-Accumulate, and Legacy Integer Multiply-Accumulate is mutually exclusive with Vector. ² The SPE-dependent Floating-Point categories are collectively referred to as SPE.Embedded Float_* or SP*.		

Figure 1. Category Listing (Sheet 2 of 2)

An instruction in a category that is not supported by the implementation is treated as an illegal instruction or an unimplemented instruction on that implementation (see Section 1.7.2).

For an instruction that is supported by the implementation with field values that are defined by the architecture, the field values defined as part of a category that is not supported by the implementation are treated as reserved values on that implementation (see Section 1.3.3 and Section 1.8.2).

Bits in a register that are in a category that is not supported by the implementation are treated as reserved.

1.3.5.1 Phased-In/Phased-Out

There are two special categories, *Phased-In* and *Phased-Out*, as well as two additional variations of

Phased-In as defined below. Abbreviations, if applicable, are shown in parentheses.

Phased-In

These are facilities and instructions that, in the next version of the architecture, will be required as part of the category they are dependent on.

Servers do not implement a facility or instruction in this category. Servers that comply with earlier versions of this architecture may have optionally implemented facilities or instructions that were category Phased-In.

**Server,
Embedded.Phased-In
(S,E.PI)**

These are facilities and instructions that are part of the Server environment and, in the next version of the architecture, will be required for the Embedded environment.

It is implementation-dependent whether Embedded processors implement a facility or instruction in this category.

**Embedded,
Server.Phased-In
(E,S.PI)**

These are facilities and instructions that are part of the Embedded environment and, in the next version of the architecture, will be required for the Server environment.

Servers do not implement a facility or instruction in this category.

Phased-Out

These are facilities and instructions that, in some future version of the architecture, will be dropped out of the architecture. System developers should develop a migration plan to eliminate use of them in new systems.

For Server platforms, Phased-Out facilities and instructions must be implemented if the facility or instruction is part of another category (including the Base category) that is supported by the Server platform.

Programming Note

Warning: Instructions and facilities being phased out of the architecture are likely to perform poorly on future implementations. New programs should not use them.

Programming Note

Facilities are categorized as Phased-In only in cases where there is a difference between the Server and Embedded environments.

1.3.5.2 Corequisite Category

A corequisite category is an additional category that is associated with an instruction or facility, and must be implemented if the instruction or facility is implemented.

1.3.5.3 Category Notation

Instructions and facilities are considered part of the Base category unless otherwise marked. If a section is marked with a specific category tag, all material in that section and its subsections are considered part of the category, unless otherwise marked. Overview sections may contain discussion of instructions and facilities from various categories without being explicitly marked.

An example of a category tag is: [Category: Server]. Alternatively, a shorthand notation of a category tag includes the category name in angled brackets “<>”, such as <E.HV>.

An example of a dependent category is:
[Category: Server.Phased-In]

The shorthand <E> and <S> may also be used for Category: Embedded and Server respectively.

1.3.6 Environments

All implementations support one of the two defined environments, Server or Embedded. Environments refer to common subsets of instructions that are shared across many implementations. The Server environment describes implementations that support Category: Base and Server. The Embedded environment describes implementations that support Category: Base and Embedded.

1.4 Processor Overview

The basic classes of instructions are as follows:

- branch instructions (Chapter 2)
- GPR-based scalar fixed-point instructions (Chapter 3, Chapter 9, and Chapter 11)
- GPR-based vector fixed-point instructions (Chapter 8)
- GPR-based scalar and vector floating-point instructions (Chapter 10)
- FPR-based scalar floating-point instructions (Chapter 4)
- FPR-based scalar decimal floating-point instructions (Chapter 5)
- VR-based vector fixed-point and floating-point instructions (Chapter 6)
- VSR-based scalar and vector floating-point instructions (Chapter 7)

Scalar fixed-point instructions operate on byte, halfword, word, doubleword, and quadword (see Book III-S) operands, where each operand contained in a GPR. Vector fixed-point instructions operate on vectors of byte, halfword, and word operands, where each vector is contained in a GPR or VR. Scalar floating-point instructions operate on single-precision or double-precision floating-point operands, where each operand is contained in a GPR, FPR, or VSR. Vector floating-point instructions operate on vectors of single-precision and double-precision floating-point operands, where each vector is contained in a GPR, VR, or VSR.

The Power ISA uses instructions that are four bytes long and word-aligned (VLE has different instruction characteristics; see Book VLE). It provides for byte, halfword, word, doubleword, and quadword operand loads and stores between storage and a set of 32 General Purpose Registers (GPRs). It provides for word and doubleword operand loads and stores between storage and a set of 32 Floating-Point Registers (FPRs). It also provides for byte, halfword, word, and quadword operand loads and stores between storage and a set of 32 Vector Registers (VRs). It provides for doubleword and quadword operand loads and stores between storage and a set of 64 Vector-Scalar Registers (VSRs).

Signed integers are represented in two's complement form.

There are no computational instructions that modify storage; instructions that reference storage may reformat the data (e.g. load halfword algebraic). To use a storage operand in a computation and then modify the same or another storage location, the contents of the storage operand must be loaded into a register, modified, and then stored back to the target location. Figure 2 is a logical representation of instruction processing. Figure 3 shows the registers that are defined in Book I. (A few additional registers that are available

to application programs are defined in other Books, and are not shown in the figure.)

Figure 3. Registers that are defined in Book I

1.5 Computation modes

1.5.1 Modes [Category: Server]

Processors provide two execution modes, 64-bit mode and 32-bit mode. In both of these modes, instructions that set a 64-bit register affect all 64 bits. The computational mode controls how the effective address is interpreted, how Condition Register bits and XER bits are set, how the Link Register is set by *Branch* instructions in which LK=1, and how the Count Register is tested by *Branch Conditional* instructions. Nearly all instructions are available in both modes (the only exceptions are a few instructions that are defined in Book III-S). In both modes, effective address computations use all 64 bits of the relevant registers (General Purpose Registers, Link Register, Count Register, etc.) and produce a 64-bit result. However, in 32-bit mode the high-order 32 bits of the computed effective address are ignored for the purpose of addressing storage; see Section 1.10.3 for additional details.

Programming Note

Although instructions that set a 64-bit register affect all 64 bits in both 32-bit and 64-bit modes, operating systems often do not preserve the upper 32-bits of all registers across context switches done in 32-bit mode. For this reason, application programs operating in 32-bit mode should not assume that the upper 32 bits of the GPRs are preserved from instruction to instruction unless the operating system is known to preserve these bits.

1.5.2 Modes [Category: Embedded]

64-bit processors provide 64-bit mode and 32-bit mode. The differences between the two modes are described below. 32-bit processors provide only 32-bit mode, and do so as described at the end of this section.

- In 64-bit mode, the processor behaves as described for 64-bit mode in the Server environment; see Section 1.5.1.
- In 32-bit mode, the processor behavior depends on whether the high-order 32 bits of GPRs are implemented in 32-bit mode, as follows.
 - If these bits are implemented in 32-bit mode, the processor behaves as described for 32-bit mode in the Server environment.
 - If these bits are not implemented in 32-bit mode, the processor behaves as described for 32-bit mode in the Server Environment except for the following.

- When an effective address is placed in a register other than the Initialize Next Instruction register (see Appendix D of Book III-E) by an instruction or event, the high-order 32 bits are set to an undefined value (see Section 1.10.3).
- Except for instructions in the SPE category, instructions that operate on GPRs and SPRs use only the low-order 32 bits of the source GPR or SPR and produce a 32-bit result; the high-order 32 bits of target GPRs are set to an undefined value, and the high-order 32 bits of target SPRs are preserved. Instructions in the 64-Bit category are treated as illegal instructions.

Programming Note

The high-order 32 bits of 64-bit SPRs are not modified in 32-bit mode because for some 64-bit SPRs, such as the Thread Enable Register (see Book III-E), these bits control facilities that are active in 32-bit mode. Treating all 64-bit SPRs the same way in this regard simplifies architecture and implementation.

Implementations may provide a means for selecting between the two treatments of the high-order 32 bits of GPRs in 32-bit mode (i.e., for selecting between the behavior described in the first sub-bullet and the behavior described in the second sub-bullet). The means, if provided, is implementation-specific (including any software synchronization requirements for changing the selection), but must be hypervisor privileged, and the hypervisor must ensure that the selection is constant for a given partition.

32-bit processors provide only 32-bit mode, and provide it as described by the second sub-bullet of the 32-bit mode bullet above.

1.6 Instruction formats

All instructions are four bytes long and word-aligned (except for VLE instructions; see Book VLE). Thus, whenever instruction addresses are presented to the processor (as in *Branch* instructions) the low-order two bits are ignored. Similarly, whenever the processor develops an instruction address the low-order two bits are zero.

Bits 0:5 always specify the opcode (OPCD, below). Many instructions also have an extended opcode (XO, below). The remaining bits of the instruction contain

one or more fields as shown below for the different instruction formats.

The format diagrams given below show horizontally all valid combinations of instruction fields. The diagrams include instruction fields that are used only by instructions defined in Book II or in Book III.

Split Field Notation

In some cases an instruction field occupies more than one contiguous sequence of bits, or occupies one contiguous sequence of bits that are used in permuted order. Such a field is called a *split field*. In the format diagrams given below and in the individual instruction layouts, the name of a split field is shown in small letters, once for each of the contiguous sequences. In the RTL description of an instruction having a split field, and in certain other places where individual bits of a split field are identified, the name of the field in small letters represents the concatenation of the sequences from left to right. In all other places, the name of the field is capitalized and represents the concatenation of the sequences in some order, which need not be left to right, as described for each affected instruction.

1.6.28 Instruction Fields

AA (30)

Absolute Address bit.

- The immediate field represents an address relative to the current instruction address. For I-form branches the effective address of the branch target is the sum of the LI field sign-extended to 64 bits and the address of the branch instruction. For B-form branches the effective address of the branch target is the sum of the BD field sign-extended to 64 bits and the address of the branch instruction.
- The immediate field represents an absolute address. For I-form branches the effective address of the branch target is the LI field sign-extended to 64 bits. For B-form branches the effective address of the branch target is the BD field sign-extended to 64 bits.

AX (29) & A(11:15)

Fields that are concatenated to specify a VSR to be used as a source.

BA (11:15)

Field used to specify a bit in the CR to be used as a source.

BB (16:20)

Field used to specify a bit in the CR to be used as a source.

BC (21:25)

Field used to specify a bit in the CR to be used as a source.

BD (16:29)

Immediate field used to specify a 14-bit signed two's complement branch displacement which is concatenated on the right with 0b00 and sign-extended to 64 bits.

BF (6:8)

Field used to specify one of the CR fields or one of the FPSCR fields to be used as a target.

BFA (11:13 or 29:31)

Field used to specify one of the CR fields or one of the FPSCR fields to be used as a source.

BH (19:20)

Field used to specify a hint in the *Branch Conditional to Link Register* and *Branch Conditional to Count Register* instructions. The encoding is described in Section 2.4, "Branch Instructions".

BI (11:15)

Field used to specify a bit in the CR to be tested by a *Branch Conditional* instruction.

BO (6:10)

Field used to specify options for the *Branch Conditional* instructions. The encoding is described in Section 2.4, "Branch Instructions".

BT (6:10)

Field used to specify a bit in the CR or in the FPSCR to be used as a target.

BX (30) & B(16:20)

Fields that are concatenated to specify a VSR to be used as a source.

CT (7:10)

Field used in X-form instructions to specify a cache target (see Section 4.3.2 of Book II).

CX (28) & C(21:25)

Fields that are concatenated to specify a VSR to be used as a source.

D (16:31)

Immediate field used to specify a 16-bit signed two's complement integer which is sign-extended to 64 bits.

DCM (16:21)

Immediate field used as the Data Class Mask.

DCR (11:20)

Field used by the *Move To/From Device Control Register* instructions (see Book III-E).

DGM (16:21)

Immediate field used as the Data Group Mask.

DM (24:25)

Immediate field used by *xxpermdi* instruction as doubleword permute control.

DQ (16:27)

Immediate field used to specify a 12-bit signed two's complement integer which is concatenated on the right with 0b0000 and sign-extended to 64 bits.

DS (16:29)

Immediate field used to specify a 14-bit signed two's complement integer which is concatenated on the right with 0b00 and sign-extended to 64 bits.

DUI (6:10)

Field used by the *dnh* instruction (see Book II).

DUIS (11:20)

Field used by the *dnh* instruction (see Book II).

E (16)

Field used by the *Write MSR External Enable* instruction (see Book III-E).

EH (31)

Field used to specify a hint in the *Load and Reserve* instructions. The meaning is described in Section 4.4.2, "Load and Reserve and Store Conditional Instructions", in Book II.

FLM (7:14)

Field mask used to identify the FPSCR fields that are to be updated by the *mtfsf* instruction.

FRA (11:15)

Field used to specify an FPR to be used as a source.

FRAp (11:15)

Field used to specify an even/odd pair of FPRs to be concatenated and used as a source.

FRB (16:20)

Field used to specify an FPR to be used as a source.

FRBp (16:20)

Field used to specify an even/odd pair of FPRs to be concatenated and used as a source.

FRC (21:25)

Field used to specify an FPR to be used as a source.

FRS (6:10)

Field used to specify an FPR to be used as a source.

FRSp (6:10)

Field used to specify an even/odd pair of FPRs to be concatenated and used as a source.

FRT (6:10)

Field used to specify an FPR to be used as a target.

FRTp (6:10)

Field used to specify an even/odd pair of FPRs to be concatenated and used as a target.

FXM (12:19)

Field mask used to identify the CR fields that are to be written by the *mtcrf* and *mtocrf* instructions, or read by the *mfocrf* instruction.

IH (8:10)

Field used to specify a hint in the *SLB Invalidate All* instruction. The meaning is described in Section 5.9.3.1, “SLB Management Instructions”, in Book III-S.

L (6)

Field used to specify whether the *mtfsf* instruction updates the entire FPSCR.

L (10 or 15)

Field used to specify whether a fixed-point Compare instruction is to compare 64-bit numbers or 32-bit numbers.

Field used by the *Data Cache Block Flush* instruction (see Section 4.3.2 of Book II).

Field used by the *Move To Machine State Register* and *TLB Invalidate Entry* instructions (see Book III).

L (9:10)

Field used by the *Synchronize* instruction (see Section 4.4.1 of Book II).

LEV (20:26)

Field used by the *System Call* instruction.

LI (6:29)

Immediate field used to specify a 24-bit signed two’s complement integer which is concatenated on the right with 0b00 and sign-extended to 64 bits.

LK (31)

LINK bit.

- 0 Do not set the Link Register.
- 1 Set the Link Register. The address of the instruction following the *Branch* instruction is placed into the Link Register.

MB (21:25) and ME (26:30)

Fields used in M-form instructions to specify a 64-bit mask consisting of 1-bits from bit MB+32 through bit ME+32 inclusive and 0-bits elsewhere, as described in Section 3.3.13, “Fixed-Point Rotate and Shift Instructions” on page 87.

MB (21:26)

Field used in MD-form and MDS-form instructions to specify the first 1-bit of a 64-bit mask, as described in Section 3.3.13, “Fixed-Point Rotate and Shift Instructions” on page 87.

ME (21:26)

Field used in MD-form and MDS-form instructions to specify the last 1-bit of a 64-bit mask, as described in Section 3.3.13, “Fixed-Point Rotate and Shift Instructions” on page 87.

MO (6:10)

Field used in X-form instructions to specify a subset of storage accesses.

NB (16:20)

Field used to specify the number of bytes to move in an immediate Move Assist instruction.

OC (6:20)

Field used by the Embedded Hypervisor Privilege instruction.

OPCD (0:5)

Primary opcode field.

OE (21)

Field used by XO-form instructions to enable setting OV and SO in the XER.

PMRN (11:20)

Field used to specify a Performance Monitor Register for the *mfpmr* and *mtpmr* instructions.

R (15)

Immediate field that specifies whether the RMC is specifying the primary or secondary encoding

RA (11:15)

Field used to specify a GPR to be used as a source or as a target.

RB (16:20)

Field used to specify a GPR to be used as a source.

Rc (21 OR 31)

RECORD bit.

- 0 Do not alter the Condition Register.
- 1 Set Condition Register Field 0, Field 1, or Field 6 as described in Section 2.3.1, “Condition Register” on page 30.

RMC (21:22)

Immediate field used for DFP rounding mode control.

RS (6:10)

Field used to specify a GPR to be used as a source.

RSp (6:10)

Field used to specify an even/odd pair of GPRs to be concatenated and used as a source.

RT (6:10)

Field used to specify a GPR to be used as a target.

RTp (6:10)

Field used to specify an even/odd pair of GPRs to be concatenated and used as a target.

S (11)

Immediate field that specifies signed versus unsigned conversion.

SH (16:20, or 16:20 and 30, or 16:21)

Field used to specify a shift amount.

SHB (22:25)

Field used to specify a shift amount in bytes.

SHW (24:25)

Field used to specify a shift amount in words.

SI (16:31 or 11:15)

Immediate field used to specify a 16-bit signed integer.

SIM (11:15)

Immediate field used to specify a 5-bit signed integer.

SP (11:12)

Immediate field that specifies signed versus unsigned conversion.

SPR (11:20)

Field used to specify a Special Purpose Register for the *mtspr* and *mfspr* instructions.

SR (12:15)

Field used by the *Segment Register Manipulation* instructions (see Book III-S).

SX (31) & S(6:10)

Fields that are concatenated to specify a VSR to be used as a source.

T(9:10)

Field used to specify the type of invalidation done by a *TLB Invalidate Local* instruction (see Book III-E).

TBR (11:20)

Field used by the *Move From Time Base* instruction (see Section 5.2.1 of Book II).

TE (11:15)

Immediate field that specifies a DFP exponent.

TH (6:10)

Field used by the data stream variant of the *dcbt* and *dcbtst* instructions (see Section 4.3.2 of Book II).

TO (6:10)

Field used to specify the conditions on which to trap. The encoding is described in Section 3.3.10, “Fixed-Point Trap Instructions” on page 76.

TX (31) & T (6:10)

Fields that are concatenated to specify a VSR to be used as a target.

U (16:19)

Immediate field used as the data to be placed into a field in the FPSCR.

UI (11:15, 16:20, or 16:31)

Immediate field used to specify an unsigned integer.

UIM (11:15, 12:15, 13:15, 14:15)

Immediate field used to specify an unsigned integer.

VRA (11:15)

Field used to specify a VR to be used as a source.

VRB (16:20)

Field used to specify a VR to be used as a source.

VRC (21:25)

Field used to specify a VR to be used as a source.

VRS (6:10)

Field used to specify a VR to be used as a source.

VRT (6:10)

Field used to specify a VR to be used as a target.

W (15)

Field used by the *mtfsfi* and *mtfsf* instructions to specify the target word in the FPSCR.

WC (9:10)

Field used to specify the condition or conditions that cause instruction execution to resume after executing a *wait* [Category: Wait] instruction (see Section 4.4.4 of Book II).

XO (21, 21:28, 21:29, 21:30, 21:31, 22:28, 22:30, 22:31, 23:30, 24:28, 26:27, 26:30, 26:31, 27:29, 27:30, or 30:31)

Extended opcode field.

1.7 Classes of Instructions

An instruction falls into exactly one of the following three classes:

Defined
Illegal
Reserved

The class is determined by examining the opcode, and the extended opcode if any. If the opcode, or combination of opcode and extended opcode, is not that of a defined instruction or a reserved instruction, the instruction is illegal.

1.7.1 Defined Instruction Class

This class of instructions contains all the instructions defined in this document.

A defined instruction can have preferred and/or invalid forms, as described in Section 1.8.1, “Preferred Instruction Forms” and Section 1.8.2, “Invalid Instruction

Forms". Instructions that are part of a category that is not supported are treated as illegal instructions.

1.7.2 Illegal Instruction Class

This class of instructions contains the set of instructions described in Appendix D of Book Appendices. Illegal instructions are available for future extensions of the Power ISA ; that is, some future version of the Power ISA may define any of these instructions to perform new functions.

Any attempt to execute an illegal instruction will cause the system illegal instruction error handler to be invoked and will have no other effect.

An instruction consisting entirely of binary 0s is guaranteed always to be an illegal instruction. This increases the probability that an attempt to execute data or uninitialized storage will result in the invocation of the system illegal instruction error handler.

1.7.3 Reserved Instruction Class

This class of instructions contains the set of instructions described in Appendix E of Book Appendices.

Reserved instructions are allocated to specific purposes that are outside the scope of the Power ISA.

Any attempt to execute a reserved instruction will:

- perform the actions described by the implementation if the instruction is implemented; or
- cause the system illegal instruction error handler to be invoked if the instruction is not implemented.

1.8 Forms of Defined Instructions

1.8.1 Preferred Instruction Forms

Some of the defined instructions have preferred forms. For such an instruction, the preferred form will execute in an efficient manner, but any other form may take significantly longer to execute than the preferred form.

Instructions having preferred forms are:

- the *Condition Register Logical* instructions
- the *Load/Store Multiple* instructions
- the *Load/Store String* instructions
- the *Or Immediate* instruction (preferred form of no-op)
- the *Move To Condition Register Fields* instruction

1.8.2 Invalid Instruction Forms

Some of the defined instructions can be coded in a form that is invalid. An instruction form is invalid if one or more fields of the instruction, excluding the opcode field(s), are coded incorrectly in a manner that can be deduced by examining only the instruction encoding.

In general, any attempt to execute an invalid form of an instruction will either cause the system illegal instruction error handler to be invoked or yield boundedly undefined results. Exceptions to this rule are stated in the instruction descriptions.

Some instruction forms are invalid because the instruction contains a reserved value in a defined field (see Section 1.3.3 on page 6); these invalid forms are not discussed further. All other invalid forms are identified in the instruction descriptions.

References to instructions elsewhere in this document assume the instruction form is not invalid, unless otherwise stated or obvious from context.

Assembler Note

Assemblers should report uses of invalid instruction forms as errors.

1.8.3 Reserved-no-op Instructions | [Category: Phased-In]

Reserved-no-op instructions include the following extended opcodes under primary opcode 31: 530, 562, 594, 626, 658, 690, 722, and 754.

Reserved-no-op instructions are provided in the architecture to anticipate the eventual adoption of performance hint instructions to the architecture. For these instructions, which cause no visible change to architected state, employing a reserved-no-op opcode will

allow software to use this new capability on new implementations that support it while remaining compatible with existing implementations that may not support the new function.

When a reserved-no-op instruction is executed, no operation is performed.

Reserved-no-op instructions are not assigned instruction names or mnemonics. There are no individual descriptions of reserved-no-op instructions in this document.

1.9 Exceptions

There are two kinds of exception, those caused directly by the execution of an instruction and those caused by an asynchronous event. In either case, the exception may cause one of several components of the system software to be invoked.

The exceptions that can be caused directly by the execution of an instruction include the following:

- an attempt to execute an illegal instruction, or an attempt by an application program to execute a “privileged” instruction (see Book III) (system illegal instruction error handler or system privileged instruction error handler)
- the execution of a defined instruction using an invalid form (system illegal instruction error handler or system privileged instruction error handler)
- an attempt to execute an instruction that is not provided by the implementation (system illegal instruction error handler)
- an attempt to access a storage location that is unavailable (system instruction storage error handler or system data storage error handler)
- an attempt to access storage with an effective address alignment that is invalid for the instruction (system alignment error handler)
- the execution of a *System Call* instruction (system service program)
- the execution of a *Trap* instruction that traps (system trap handler)
- the execution of a floating-point instruction that causes a floating-point enabled exception to exist (system floating-point enabled exception error handler)
- the execution of an auxiliary processor instruction that causes an auxiliary processor enabled exception to exist (system auxiliary processor enabled exception error handler)

The exceptions that can be caused by an asynchronous event are described in Book III.

The invocation of the system error handler is precise, except that the invocation of the auxiliary processor enabled exception error handler may be imprecise, and if one of the imprecise modes for invoking the system floating-point enabled exception error handler is in effect (see page 115), then the invocation of the system floating-point enabled exception error handler may also be imprecise. When the system error handler is invoked imprecisely, the excepting instruction does not appear to complete before the next instruction starts (because one of the effects of the excepting instruction, namely the invocation of the system error handler, has not yet occurred).

Additional information about exception handling can be found in Book III.

1.10 Storage Addressing

A program references storage using the effective address computed by the processor when it executes a *Storage Access* or *Branch* instruction (or certain other instructions described in Book II and Book III), or when it fetches the next sequential instruction.

Bytes in storage are numbered consecutively starting with 0. Each number is the address of the corresponding byte.

The byte ordering (Big-Endian or Little-Endian) for a storage access is specified by the operating system. In the Embedded environment this ordering is a page attribute (see Book II) and is specified independently for each virtual page, while in the Server environment it is a mode (see Book III-S) and applies to all storage.

1.10.1 Storage Operands

A storage operand may be a byte, a halfword, a word, a doubleword, or a quadword, or, for the *Load/Store Multiple* and *Move Assist* instructions, a sequence of bytes (*Move Assist*) or words (*Load/Store Multiple*). For example, the storage operand of a *Load Floating-Point Double Pair* instruction is a quadword, not two doublewords. The address of a storage operand is the address of its first byte (i.e., of its lowest-numbered byte). An instruction for which the storage operand is a byte is said to cause a byte access, and similarly for halfword, word, doubleword, and quadword.

Operand length is implicit for each instruction.

The storage operand of a single-register *Storage Access* instruction or quadword *Load* or *Store* instruction has a “natural” alignment boundary equal to the operand length. In other words, the “natural” address of such an operand is an integral multiple of the operand length. Such an operand is said to be *aligned* if it is

aligned at its natural boundary; otherwise it is said to be *unaligned*. See the following table.

Operand	Length	Addr _{60:63} if aligned
Byte	8 bits	xxxx
Halfword	2 bytes	xxx0
Word	4 bytes	xx00
Doubleword	8 bytes	x000
Quadword	16 bytes	0000

Note: An “x” in an address bit position indicates that the bit can be 0 or 1 independent of the contents of other bits in the address.

The concept of alignment is also applied more generally, to any datum in storage. For example, a 12-byte datum in storage is said to be word-aligned if its address is an integral multiple of 4.

Some instructions require their storage operands to have certain alignments. In addition, alignment may affect performance. For single-register *Storage Access* instructions and quadword *Load* and *Store* instructions, the best performance is obtained when storage operands are aligned. Additional effects of data placement on performance are described in Chapter 2 of Book II.

When a storage operand of length N bytes starting at effective address EA is copied between storage and a register that is R bytes long (i.e., the register contains bytes numbered from 0, most significant, through R-1, least significant), the bytes of the operand are placed into the register or into storage in a manner that depends on the byte ordering for the storage access as shown in Figure 31, unless otherwise specified in the instruction description.

Big-Endian Byte Ordering	
Load	Store
for i=0 to N-1: RT _{(R-N)+i} ← MEM(EA+i,1)	for i=0 to N-1: MEM(EA+i,1) ← (RS) _{(R-N)+i}
Little-Endian Byte Ordering	
Load	Store
for i=0 to N-1: RT _{(R-1)-i} ← MEM(EA+i,1)	for i=0 to N-1: MEM(EA+i,1) ← (RS) _{(R-1)-i}
Notes:	
1. In this table, subscripts refer to bytes in a register rather than to bits as defined in Section 1.3.2.	
2. This table does not apply to the <i>lvebx</i> , <i>lvehx</i> , <i>lvewx</i> , <i>stvebx</i> , <i>stvehx</i> , and <i>stvewx</i> instructions.	

Figure 31. Storage operands and byte ordering

Figure 32 shows an example of a C language structure `s` containing an assortment of scalars and one character string. The value assumed to be in each structure element is shown in hex in the C comments; these values are used below to show how the bytes making up each structure element are mapped into storage. It is assumed that structure `s` is compiled for

32-bit mode or for a 32-bit implementation. (This affects the length of the pointer to c.)

C structure mapping rules permit the use of padding (skipped bytes) in order to align the scalars on desirable boundaries. Figures 33 and 34 show each scalar aligned at its natural boundary. This alignment introduces padding of four bytes between **a** and **b**, one byte between **d** and **e**, and two bytes between **e** and **f**. The same amount of padding is present for both Big-Endian and Little-Endian mappings.

```

struct {
    int    a;      /* 0x1112_1314          word          */
    double b;     /* 0x2122_2324_2526_2728 doubleword    */
    char * c;     /* 0x3132_3334          word          */
    char  d[7];  /* 'A','B','C','D','E','F','G' array of bytes */
    short e;     /* 0x5152              halfword     */
    int   f;     /* 0x6162_6364          word          */
} s;
    
```

Figure 34. Little-Endian mapping of structure 's'

The Big-Endian mapping of structure **s** is shown in Figure 33. Addresses are shown in hex at the left of each doubleword, and in small figures below each byte. The contents of each byte, as indicated in the C example in Figure 32, are shown in hex (as characters for the elements of the string).

The Little-Endian mapping of structure **s** is shown in Figure 34. Doublewords are shown laid out from right to left, which is the common way of showing storage maps for processors that implement only Little-Endian byte ordering.

1.10.2 Instruction Fetches

Instructions are always four bytes long and word-aligned (except for VLE instructions; see Book VLE).

When an instruction starting at effective address **EA** is fetched from storage, the relative order of the bytes within the instruction depend on the byte ordering for the storage access as shown in Figure 35.

Big-Endian Byte Ordering
for i=0 to 3: inst _i ← MEM(EA+i,1)
Little-Endian Byte Ordering
for i=0 to 3: inst _{3-i} ← MEM(EA+i,1)
Note: In this table, subscripts refer to bytes of the instruction rather than to bits as defined in Section 1.3.2.

Figure 38. Little-Endian mapping of program 'p'

Programming Note

The terms *Big-Endian* and *Little-Endian* come from Part I, Chapter 4, of Jonathan Swift's *Gulliver's Travels*. Here is the complete passage, from the edition printed in 1734 by George Faulkner in Dublin.

... our Histories of six Thousand Moons make no Mention of any other Regions, than the two great Empires of *Lilliput* and *Blefuscu*. Which two mighty Powers have, as I was going to tell you, been engaged in a most obstinate War for six and thirty Moons past. It began upon the following Occasion. It is allowed on all Hands, that the primitive Way of breaking Eggs before we eat them, was upon the larger End: But his present Majesty's Grand-father, while he was a Boy, going to eat an Egg, and breaking it according to the ancient Practice, happened to cut one of his Fingers. Whereupon the Emperor his Father, published an Edict, commanding all his Subjects, upon great Penalties, to break the smaller End of their Eggs. The People so highly resented this Law, that our Histories tell us, there have been six Rebellions raised on that Account; wherein one Emperor lost his Life, and another his Crown. These civil Commotions were constantly fomented by the Monarchs of *Blefuscu*; and when they were quelled, the Exiles always fled for Refuge to that Empire. It is computed that eleven Thousand Persons have, at several Times, suffered Death, rather than submit to break their Eggs at the smaller End. Many hundred large Volumes have been published upon this Controversy: But the Books of the *Big-Endians* have been long

forbidden, and the whole Party rendered incapable by Law of holding Employments. During the Course of these Troubles, the Emperors of *Blefuscu* did frequently expostulate by their Ambassadors, accusing us of making a Schism in Religion, by offending against a fundamental Doctrine of our great Prophet *Lustrog*, in the fifty-fourth Chapter of the *Brundrecal*, (which is their *Alcoran*.) This, however, is thought to be a mere Strain upon the text: For the Words are these; *That all true Believers shall break their Eggs at the convenient End*: and which is the convenient End, seems, in my humble Opinion, to be left to every Man's Conscience, or at least in the Power of the chief Magistrate to determine. Now the *Big-Endian* Exiles have found so much Credit in the Emperor of *Blefuscu's* Court; and so much private Assistance and Encouragement from their Party here at home, that a bloody War has been carried on between the two Empires for six and thirty Moons with various Success; during which Time we have lost Forty Capital Ships, and a much greater Number of smaller Vessels, together with thirty thousand of our best Seamen and Soldiers; and the Damage received by the Enemy is reckoned to be somewhat greater than ours. However, they have now equipped a numerous Fleet, and are just preparing to make a Descent upon us: and his Imperial Majesty, placing great Confidence in your Valour and Strength, hath commanded me to lay this Account of his Affairs before you.

1.10.3 Effective Address Calculation

An effective address is computed by the processor when executing a *Storage Access* or *Branch* instruction (or certain other instructions described in Book II, Book III, and Book VLE) when fetching the next sequential instruction, or when invoking a system error handler. The following provides an overview of this process. More detail is provided in the individual instruction descriptions.

Effective address calculations, for both data and instruction accesses, use 64-bit two's complement addition. All 64 bits of each address component participate in the calculation regardless of mode (32-bit or 64-bit). In this computation one operand is an address (which is by definition an unsigned number) and the second is a signed offset. Carries out of the most significant bit are ignored.

In 64-bit mode, the entire 64-bit result comprises the 64-bit effective address. The effective address arithmetic wraps around from the maximum address, $2^{64} - 1$, to address 0, except that if the current instruction is at effective address $2^{64} - 4$ the effective address of the next sequential instruction is undefined.

In 32-bit mode, the low-order 32 bits of the 64-bit result, preceded by 32 0 bits, comprise the 64-bit effective address for the purpose of addressing storage. When an effective address is placed into a register by an instruction or event, the value placed into the high-order 32 bits of the register differs between the Server environment and the Embedded environment.

- Server environment, and Embedded Environment when the high-order 32 bits of GPRs are implemented:
 - Load with Update and Store with Update instructions set the high-order 32 bits of register RA to the high-order 32 bits of the 64-bit result.

- In all other cases (e.g., the Link Register when set by Branch instructions having LK=1, Special Purpose Registers when set to an effective address by invocation of a system error handler) the high-order 32 bits of the register are set to 0s except as described in the last sentence of this paragraph.
- Embedded environment when the high-order 32 bits of GPRs are not implemented for the following cases:
The high-order 32 bits of the register are set to an undefined value except for the Initialize Next Instruction register [Category: Embedded.Multi-threading] (see Section 1.5.2 and Book III), and for the following case. For a register that is loaded with an effective address by the invocation of a system error handler, the high-order 32 bits of the register are set to 0s if the computation mode is 64-bit after the system error is invoked. The 64-bit current instruction address is not affected by a change from 32-bit mode to 64-bit mode, but is affected by a change from 64-bit mode to 32-bit mode. In the latter case, the high-order 32 bits are set to 0. The same is true for the 64-bit next instruction address, except as described in the last item of the list below.

As used to address storage, the effective address arithmetic appears to wrap around from the maximum address, $2^{32} - 1$, to address 0, except that if the current instruction is at effective address $2^{32} - 4$ the effective address of the next sequential instruction is undefined.

RA is a field in the instruction which specifies an address component in the computation of an effective address. A zero in the RA field indicates the absence of the corresponding address component. A value of zero is substituted for the absent component of the effective address computation. This substitution is shown in the instruction descriptions as (RAI0).

Effective addresses are computed as follows. In the descriptions below, it should be understood that “the contents of a GPR” refers to the entire 64-bit contents, independent of mode, but that in 32-bit mode only bits 32:63 of the 64-bit result of the computation are used to address storage.

- With X-form instructions, in computing the effective address of a data element, the contents of the GPR designated by RB (or the value zero for *lswi* and *stswi*) are added to the contents of the GPR designated by RA or to zero if RA=0 or RA is not used in forming the EA.
- With D-form instructions, the 16-bit D field is sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0.
- With DS-form instructions, the 14-bit DS field is concatenated on the right with 0b00 and sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0.
- With I-form Branch instructions, the 24-bit LI field is concatenated on the right with 0b00 and sign-extended to form a 64-bit address component. If AA=0, this address component is added to the address of the Branch instruction to form the effective address of the target instruction. If AA=1, this address component is the effective address of the target instruction.
- With B-form Branch instructions, the 14-bit BD field is concatenated on the right with 0b00 and sign-extended to form a 64-bit address component. If AA=0, this address component is added to the address of the Branch instruction to form the effective address of the target instruction. If AA=1, this address component is the effective address of the target instruction.
- With XL-form Branch instructions, bits 0:61 of the Link Register or the Count Register are concatenated on the right with 0b00 to form the effective address of the target instruction.
- With sequential instruction fetching, the value 4 is added to the address of the current instruction to form the effective address of the next instruction, except that if the current instruction is at the maximum instruction effective address for the mode ($2^{64} - 4$ in 64-bit mode, $2^{32} - 4$ in 32-bit mode) the effective address of the next sequential instruction is undefined. (There is one other exception to this rule; this exception involves changing between 32-bit mode and 64-bit mode and is described in Section 6.3.2 of Book III-E and Section 6.3.2 of Book III-E.)

If the size of the operand of a storage access instruction is more than one byte, the effective address for each byte after the first is computed by adding 1 to the effective address of the preceding byte.

Chapter 2. Branch Facility

2.1 Branch Facility Overview	29	2.5 Condition Register Instructions	37
2.2 Instruction Execution Order	29	2.5.1 Condition Register Logical

2.3.2 Link Register	31	Instruction	38
2.3.3 Count Register	31	2.6 System Call Instruction	39
2.4 Branch Instructions	31		

2.1 Branch Facility Overview

This chapter describes the registers and instructions that make up the Branch Facility.

2.2 Instruction Execution Order

In general, instructions appear to execute sequentially, in the order in which they appear in storage. The exceptions to this rule are listed below.

- *Branch* instructions for which the branch is taken cause execution to continue at the target address specified by the Branch instruction.
- *Trap* instructions for which the trap conditions are satisfied, and *System Call* instructions, cause the appropriate system handler to be invoked.
- Exceptions can cause the system error handler to be invoked, as described in Section 1.9, “Exceptions” on page 23.
- Returning from a system service program, system trap handler, or system error handler causes execution to continue at a specified address.

The model of program execution in which the processor appears to execute one instruction at a time, completing each instruction before beginning to execute the next instruction is called the “sequential execution model”. In general, the processor obeys the sequential execution model. For the instructions and facilities defined in this Book, the only exceptions to this rule are the following.

- A floating-point exception occurs when the processor is running in one of the Imprecise floating-point exception modes (see Section 4.4). The instruction

that causes the exception need not complete before the next instruction begins execution, with respect to setting exception bits and (if the exception is enabled) invoking the system error handler.

- A Store instruction modifies one or more bytes in an area of storage that contains instructions that will subsequently be executed. Before an instruction in that area of storage is executed, software synchronization is required to ensure that the instructions executed are consistent with the results produced by the Store instruction.

Programming Note

This software synchronization will generally be provided by system library programs (see Section 1.8 of Book II). Application programs should call the appropriate system library program before attempting to execute modified instructions.

2.3 Branch Facility Registers

2.3.1 Condition Register

The Condition Register (CR) is a 32-bit register which reflects the result of certain operations, and provides a mechanism for testing (and branching).

Figure 39. Condition Register

The bits in the Condition Register are grouped into eight 4-bit fields, named CR Field 0 (CR0), ..., CR Field 7 (CR7), which are set in one of the following ways.

- Specified fields of the CR can be set by a move to the CR from a GPR (*mcrf*, *mtocrf*).
- A specified field of the CR can be set by a move to the CR from another CR field (*mcrf*), from XER_{32:35} (*mcrxr*), or from the FPSCR (*mcrfs*).
- CR Field 0 can be set as the implicit result of a fixed-point instruction.
- CR Field 1 can be set as the implicit result of a floating-point instruction.
- CR Field 6 can be set as the implicit result of a vector instruction.
- A specified CR field can be set as the result of a *Compare* instruction.
- CR Field 1 can be set as the implicit result of a decimal floating-point instruction.

Instructions are provided to perform logical operations on individual CR bits and to test individual CR bits.

For all fixed-point instructions in which Rc=1, and for *addc.*, *andi.*, and *andis.*, the first three bits of CR Field 0 (bits 32:34 of the Condition Register) are set by signed comparison of the result to zero, and the fourth bit of CR Field 0 (bit 35 of the Condition Register) is copied from the SO field of the XER. “Result” here refers to the entire 64-bit value placed into the target register in 64-bit mode, and to bits 32:63 of the 64-bit value placed into the target register in 32-bit mode.

```
if (64-bit mode)
  then M ← 0
  else M ← 32
if (target_register)M:63 < 0 then c ← 0b100
else if (target_register)M:63 > 0 then c ← 0b010
else c ← 0b001
CR0 ← c || XERSO
```

If any portion of the result is undefined, then the value placed into the first three bits of CR Field 0 is undefined.

The bits of CR Field 0 are interpreted as follows.

Bit	Description
0	Negative (LT) The result is negative.
1	Positive (GT) The result is positive.
2	Zero (EQ) The result is zero.
3	Summary Overflow (SO) This is a copy of the contents of XER _{SO} at the completion of the instruction.

The *stbcx.*, *sthcx.*, *stwcx.*, and *stdcx.* instructions (see Section 4.4.2, “Load and Reserve and Store Conditional Instructions”, in Book II) also set CR Field 0.

For all floating-point instructions in which Rc=1, CR Field 1 (bits 36:39 of the Condition Register) is set to the Floating-Point exception status, copied from bits 0:3 of the Floating-Point Status and Control Register. This occurs regardless of whether any exceptions are enabled, and regardless of whether the writing of the result is suppressed (see Section 4.4, “Floating-Point Exceptions” on page 114). These bits are interpreted as follows.

Bit	Description
0	Floating-Point Exception Summary (FX) This is a copy of the contents of FPSCR _{FX} at the completion of the instruction.
1	Floating-Point Enabled Exception Summary (FEX) This is a copy of the contents of FPSCR _{FEX} at the completion of the instruction.
2	Floating-Point Invalid Operation Exception Summary (VX) This is a copy of the contents of FPSCR _{VX} at the completion of the instruction.
3	Floating-Point Overflow Exception (OX) This is a copy of the contents of FPSCR _{OX} at the completion of the instruction.

For *Compare* instructions, a specified CR field is set to reflect the result of the comparison. The bits of the specified CR field are interpreted as follows. A complete description of how the bits are set is given in the instruction descriptions in Section 3.3.9, “Fixed-Point Compare Instructions” on page 74, Section 4.6.8, “Floating-Point Compare Instructions” on page 148, and Section 8.3.9, “SPE Instruction Set” on page 510.

Bit	Description
0	Less Than, Floating-Point Less Than (LT, FL) For fixed-point Compare instructions, (RA) < SI or (RB) (signed comparison) or (RA) < ^U UI or (RB) (unsigned comparison). For floating-point Compare instructions, (FRA) < (FRB).

- 1 **Greater Than, Floating-Point Greater Than** (GT, FG)
For fixed-point Compare instructions, (RA) > SI or (RB) (signed comparison) or (RA) >^U UI or (RB) (unsigned comparison). For floating-point Compare instructions, (FRA) > (FRB).
- 2 **Equal, Floating-Point Equal** (EQ, FE)
For fixed-point Compare instructions, (RA) = SI, UI, or (RB). For floating-point Compare instructions, (FRA) = (FRB).
- 3 **Summary Overflow, Floating-Point Unordered** (SO,FU)
For fixed-point Compare instructions, this is a copy of the contents of XER_{SO} at the completion of the instruction. For floating-point Compare instructions, one or both of (FRA) and (FRB) is a NaN.

2.3.2 Link Register

The Link Register (LR) is a 64-bit register. It can be used to provide the branch target address for the *Branch Conditional to Link Register* instruction, and it holds the return address after Branch instructions for which LK=1.

Figure 40. Link Register

2.3.3 Count Register

The Count Register (CTR) is a 64-bit register. It can be used to hold a loop count that can be decremented during execution of Branch instructions that contain an appropriately coded BO field. If the value in the Count Register is 0 before being decremented, it is -1 afterward. The Count Register can also be used to provide the branch target address for the *Branch Conditional to Count Register* instruction.

Figure 41. Count Register

2.4 Branch Instructions

The sequence of instruction execution can be changed by the *Branch* instructions. Because all instructions are on word boundaries, bits 62 and 63 of the generated branch target address are ignored by the processor in performing the branch.

The *Branch* instructions compute the effective address (EA) of the target in one of the following four ways, as described in Section 1.10.3, "Effective Address Calculation" on page 27.

1. Adding a displacement to the address of the *Branch* instruction (*Branch* or *Branch Conditional* with AA=0).
2. Specifying an absolute address (*Branch* or *Branch Conditional* with AA=1).
3. Using the address contained in the Link Register (*Branch Conditional to Link Register*).
4. Using the address contained in the Count Register (*Branch Conditional to Count Register*).

In all four cases, in 32-bit mode the final step in the address computation is setting the high-order 32 bits of the target address to 0.

For the first two methods, the target addresses can be computed sufficiently ahead of the *Branch* instruction that instructions can be prefetched along the target path. For the third and fourth methods, prefetching instructions along the target path is also possible provided the Link Register or the Count Register is loaded sufficiently ahead of the *Branch* instruction.

Branching can be conditional or unconditional, and the return address can optionally be provided. If the return address is to be provided (LK=1), the effective address of the instruction following the *Branch* instruction is placed into the Link Register after the branch target address has been computed; this is done regardless of whether the branch is taken.

For *Branch Conditional* instructions, the BO field specifies the conditions under which the branch is taken, as shown in Figure 42. In the figure, M=0 in 64-bit mode and M=32 in 32-bit mode.

BO	Description
0000z	Decrement the CTR, then branch if the decremented $CTR_{M:63} \neq 0$ and $CR_{BI}=0$
0001z	Decrement the CTR, then branch if the decremented $CTR_{M:63}=0$ and $CR_{BI}=0$
001at	Branch if $CR_{BI}=0$
0100z	Decrement the CTR, then branch if the decremented $CTR_{M:63} \neq 0$ and $CR_{BI}=1$
0101z	Decrement the CTR, then branch if the decremented $CTR_{M:63}=0$ and $CR_{BI}=1$
011at	Branch if $CR_{BI}=1$
1a00t	Decrement the CTR, then branch if the decremented $CTR_{M:63} \neq 0$
1a01t	Decrement the CTR, then branch if the decremented $CTR_{M:63}=0$
1z1zz	Branch always
Notes:	
1. “z” denotes a bit that is ignored.	
2. The “a” and “t” bits are used as described below.	

Figure 42. BO field encodings

The “a” and “t” bits of the BO field can be used by software to provide a hint about whether the branch is likely to be taken or is likely not to be taken, as shown in Figure 43.

at	Hint
00	No hint is given
01	Reserved
10	The branch is very likely not to be taken
11	The branch is very likely to be taken

Figure 43. “at” bit encodings

Programming Note

Many implementations have dynamic mechanisms for predicting whether a branch will be taken. Because the dynamic prediction is likely to be very accurate, and is likely to be overridden by any hint provided by the “at” bits, the “at” bits should be set to 0b00 unless the static prediction implied by $at=0b10$ or $at=0b11$ is highly likely to be correct.

For *Branch Conditional to Link Register* and *Branch Conditional to Count Register* instructions, the BH field

provides a hint about the use of the instruction, as shown in Figure 44.

BH	Hint
00	bclr[l] : The instruction is a subroutine return bcctr[l] : The instruction is not a subroutine return; the target address is likely to be the same as the target address used the preceding time the branch was taken
01	bclr[l] : The instruction is not a subroutine return; the target address is likely to be the same as the target address used the preceding time the branch was taken bcctr[l] : Reserved
10	Reserved
11	bclr[l] and bcctr[l] : The target address is not predictable

Figure 44. BH field encodings

Programming Note

The hint provided by the BH field is independent of the hint provided by the “at” bits (e.g., the BH field provides no indication of whether the branch is likely to be taken).

Extended mnemonics for branches

Many extended mnemonics are provided so that *Branch Conditional* instructions can be coded with portions of the BO and BI fields as part of the mnemonic rather than as part of a numeric operand. Some of these are shown as examples with the Branch instructions. See Appendix E for additional extended mnemonics.

Programming Note

The hints provided by the “at” bits and by the BH field do not affect the results of executing the instruction.

The “z” bits should be set to 0, because they may be assigned a meaning in some future version of the architecture.

Programming Note

Many implementations have dynamic mechanisms for predicting the target addresses of *bclr*[*f*] and *bcctr*[*f*] instructions. These mechanisms may cache return addresses (i.e., Link Register values set by *Branch* instructions for which LK=1 and for which the branch was taken, other than the special form shown in the first example below) and recently used branch target addresses. To obtain the best performance across the widest range of implementations, the programmer should obey the following rules.

- Use *Branch* instructions for which LK=1 only as subroutine calls (including function calls, etc.), or in the special form shown in the first example below.
- Pair each subroutine call (i.e., each *Branch* instruction for which LK=1 and the branch is taken, other than the special form shown in the first example below) with a *bclr* instruction that returns from the subroutine and has BH=0b00.
- Do not use *bclr* as a subroutine call. (Some implementations access the return address cache at most once per instruction; such implementations are likely to treat *bclr* as a subroutine return, and not as a subroutine call.)
- For *bclr*[*f*] and *bcctr*[*f*], use the appropriate value in the BH field.

The following are examples of programming conventions that obey these rules. In the examples, BH is assumed to contain 0b00 unless otherwise stated. In addition, the “at” bits are assumed to be coded appropriately.

Let A, B, and Glue be specific programs.

- Obtaining the address of the next instruction:
Use the following form of *Branch and Link*.
`bcl 20,31,$+4`
- Loop counts:
Keep them in the Count Register, and use a *bc* instruction (LK=0) to decrement the count and to branch back to the beginning of the loop if the decremented count is nonzero.
- Computed goto's, case statements, etc.:
Use the Count Register to hold the address to

branch to, and use a *bcctr* instruction (LK=0, and BH=0b11 if appropriate) to branch to the selected address.

- Direct subroutine linkage:
Here A calls B and B returns to A. The two branches should be as follows.
 - A calls B: use a *bl* or *bcl* instruction (LK=1).
 - B returns to A: use a *bclr* instruction (LK=0) (the return address is in, or can be restored to, the Link Register).
- Indirect subroutine linkage:
Here A calls Glue, Glue calls B, and B returns to A rather than to Glue. (Such a calling sequence is common in linkage code used when the subroutine that the programmer wants to call, here B, is in a different module from the caller; the Binder inserts “glue” code to mediate the branch.) The three branches should be as follows.
 - A calls Glue: use a *bl* or *bcl* instruction (LK=1).
 - Glue calls B: place the address of B into the Count Register, and use a *bcctr* instruction (LK=0).
 - B returns to A: use a *bclr* instruction (LK=0) (the return address is in, or can be restored to, the Link Register).
- Function call:
Here A calls a function, the identity of which may vary from one instance of the call to another, instead of calling a specific program B. This case should be handled using the conventions of the preceding two bullets, depending on whether the call is direct or indirect, with the following differences.
 - If the call is direct, place the address of the function into the Count Register, and use a *bcctr* instruction (LK=1) instead of a *bl* or *bcl* instruction.
 - For the *bcctr*[*f*] instruction that branches to the function, use BH=0b11 if appropriate.

Compatibility Note

The bits corresponding to the current “a” and “t” bits, and to the current “z” bits except in the “branch always” BO encoding, had different meanings in versions of the architecture that precede Version 2.00.

- The bit corresponding to the “t” bit was called the “y” bit. The “y” bit indicated whether to use the architected default prediction (y=0) or to use the complement of the default prediction (y=1). The default prediction was defined as follows.
 - If the instruction is *bc[l][a]* with a negative value in the displacement field, the branch is taken. (This is the only case in which the prediction corresponding to the “y” bit differs from the prediction corresponding to the “t” bit.)
 - In all other cases (*bc[l][a]* with a nonnegative value in the displacement field, *bclr[l]*, or *bcctr[l]*), the branch is not taken.
- The BO encodings that test both the Count Register and the Condition Register had a “y” bit in place of the current “z” bit. The meaning of the “y” bit was as described in the preceding item.
- The “a” bit was a “z” bit.

Because these bits have always been defined either to be ignored or to be treated as hints, a given program will produce the same result on any implementation regardless of the values of the bits. Also, because even the “y” bit is ignored, in practice, by most processors that comply with versions of the architecture that precede Version 2.00, the performance of a given program on those processors will not be affected by the values of the bits.

Branch		I-form	Branch Conditional		B-form
b	target_addr	(AA=0 LK=0)	bc	BO,BI,target_addr	(AA=0 LK=0)
ba	target_addr	(AA=1 LK=0)	bca	BO,BI,target_addr	(AA=1 LK=0)
bl	target_addr	(AA=0 LK=1)	bcl	BO,BI,target_addr	(AA=0 LK=1)
bla	target_addr	(AA=1 LK=1)	bcla	BO,BI,target_addr	(AA=1 LK=1)

18	LI	AA	LK
0	6	30	31

```

if AA then NIA ←iea EXTS(LI || 0b00)
else      NIA ←iea CIA + EXTS(LI || 0b00)
if LK then LR ←iea CIA + 4

```

target_addr specifies the branch target address.

If AA=0 then the branch target address is the sum of LI || 0b00 sign-extended and the address of this instruction, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If AA=1 then the branch target address is the value LI || 0b00 sign-extended, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the Branch instruction is placed into the Link Register.

Special Registers Altered:

LR (if LK=1)

16	BO	BI	BD	AA	LK
0	6	11	16	30	31

```

if (64-bit mode)
  then M ← 0
  else M ← 32
if ¬BO2 then CTR ← CTR - 1
ctr_ok ← BO2 | ((CTRM:63 ≠ 0) ⊕ BO3)
cond_ok ← BO0 | (CRBI+32 ≡ BO1)
if ctr_ok & cond_ok then
  if AA then NIA ←iea EXTS(BD || 0b00)
  else      NIA ←iea CIA + EXTS(BD || 0b00)
if LK then LR ←iea CIA + 4

```

BI+32 specifies the Condition Register bit to be tested. The BO field is used to resolve the branch as described in Figure 42. *target_addr* specifies the branch target address.

If AA=0 then the branch target address is the sum of BD || 0b00 sign-extended and the address of this instruction, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If AA=1 then the branch target address is the value BD || 0b00 sign-extended, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the *Branch* instruction is placed into the Link Register.

Special Registers Altered:

CTR (if BO₂=0)
LR (if LK=1)

Extended Mnemonics:

Examples of extended mnemonics for *Branch Conditional*:

Extended:		Equivalent to:

```

if (64-bit mode)
  then M ← 0
  else M ← 32
if ¬BO2 then CTR ← CTR - 1
ctr_ok ← BO2 | ((CTRM:63 ≠ 0) ⊕ BO3)
cond_ok ← BO0 | (CRBI+32 ≡ BO1)
if ctr_ok & cond_ok then NIA ←iea LR0:61 || 0b00
if LK then LR ←iea CIA + 4

```

BI+32 specifies the Condition Register bit to be tested. The BO field is used to resolve the branch as described in Figure 42. The BH field is used as described in Figure 44. The branch target address is LR_{0:61} || 0b00, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the *Branch* instruction is placed into the Link Register.

Special Registers Altered:

CTR (if BO₂=0)
LR (if LK=1)

Extended Mnemonics:

Examples of extended mnemonics for *Branch Conditional to Link Register*:

Extended:	Equivalent to:
bclr 4,6	bclr 4,6,0
bltr	bclr 12,0,0
bnclr cr2	bclr 4,10,0
bdnzlr	bclr 16,0,0

Programming Note

bclr, **bcrlr**, **bcctr**, and **bcctrl** each serve as both a basic and an extended mnemonic. The Assembler will recognize a **bclr**, **bcrlr**, **bcctr**, or **bcctrl** mnemonic with three operands as the basic form, and a **bclr**, **bcrlr**, **bcctr**, or **bcctrl** mnemonic with two operands as the extended form. In the extended form the BH operand is omitted and assumed to be 0b00.

Branch Conditional to Count Register XL-form

bcctr BO,BI,BH (LK=0)
bcctrl BO,BI,BH (LK=1)

```

cond_ok ← BO0 | (CRBI+32 ≡ BO1)
if cond_ok then NIA ←iea CTR0:61 || 0b00
if LK then LR ←iea CIA + 4

```

BI+32 specifies the Condition Register bit to be tested. The BO field is used to resolve the branch as described in Figure 42. The BH field is used as described in Figure 44. The branch target address is CTR_{0:61} || 0b00, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the *Branch* instruction is placed into the Link Register.

If the “decrement and test CTR” option is specified (BO₂=0), the instruction form is invalid.

Special Registers Altered:

LR (if LK=1)

Extended Mnemonics:

Examples of extended mnemonics for *Branch Conditional to Count Register*:

Extended:	Equivalent to:
bcctr 4,6	bcctr 4,6,0
blctr	bcctr 12,0,0
bnctr cr2	bcctr 4,10,0

2.5 Condition Register Instructions

2.5.1 Condition Register Logical Instructions

The *Condition Register Logical* instructions have preferred forms; see Section 1.8.1. In the preferred forms, the BT and BB fields satisfy the following rule.

- The bit specified by BT is in the same Condition Register field as the bit specified by BB.

Extended mnemonics for Condition Register logical operations

A set of extended mnemonics is provided that allow additional Condition Register logical operations, beyond those provided by the basic *Condition Register Logical* instructions, to be coded easily. Some of these are shown as examples with the *Condition Register Logical* instructions. See Appendix E for additional extended mnemonics.

Condition Register AND

XL-form

2.6 System Call Instruction

This instruction provides the means by which a program can call upon the system to perform a service.

System Call *SC-form*

sc LEV

17	///	///	//	LEV	//	1	/
0	6	11	16	20	27	30	31

This instruction calls the system to perform a service. A complete description of this instruction can be found in Book III.

The use of the LEV field is described in Book III. The LEV values greater than 1 are reserved, and bits 0:5 of the LEV field (instruction bits 20:25) are treated as a reserved field.

When control is returned to the program that executed the *System Call* instruction, the contents of the registers will depend on the register conventions used by the program providing the system service.

This instruction is context synchronizing (see Book III).

Special Registers Altered:

Dependent on the system service

Programming Note

sc serves as both a basic and an extended mnemonic. The Assembler will recognize an **sc** mnemonic with one operand as the basic form, and an **sc** mnemonic with no operand as the extended form. In the extended form the LEV operand is omitted and assumed to be 0.

In application programs the value of the LEV operand for **sc** should be 0.

3.1 Fixed-Point Facility Overview

This chapter describes the registers and instructions that make up the Fixed-Point Facility.

3.2 Fixed-Point Facility Registers

3.2.1 General Purpose Registers

All manipulation of information is done in registers internal to the Fixed-Point Facility. The principal storage internal to the Fixed-Point Facility is a set of 32 General Purpose Registers (GPRs). See Figure 45.

Figure 45. General Purpose Registers

Each GPR is a 64-bit register.

3.2.2 Fixed-Point Exception Register

The Fixed-Point Exception Register (XER) is a 64-bit register.

Figure 46. Fixed-Point Exception Register

The bit definitions for the Fixed-Point Exception Register are shown below. Here M=0 in 64-bit mode and M=32 in 32-bit mode.

The bits are set based on the operation of an instruction considered as a whole, not on intermediate results (e.g., the *Subtract From Carrying* instruction, the result of which is specified as the sum of three values, sets bits in the Fixed-Point Exception Register based on the entire operation, not on an intermediate sum).

Bit(s)	Description
--------	-------------

0:31	Reserved
------	----------

32	Summary Overflow (SO)
----	------------------------------

The Summary Overflow bit is set to 1 whenever an instruction (except *mtspr*) sets the Overflow bit. Once set, the SO bit remains set until it is cleared by an *mtspr* instruction (specifying the XER) or an *mcrxr* instruction. It is not altered by *Compare* instructions, nor by other instructions (except *mtspr* to the XER, and *mcrxr*) that cannot overflow. Executing an *mtspr* instruction to the XER, supplying the values 0 for SO and 1 for OV,

causes SO to be set to 0 and OV to be set to 1.

33	Overflow (OV)
----	----------------------

The Overflow bit is set to indicate that an overflow has occurred during execution of an instruction.

XO-form *Add*, *Subtract From*, and *Negate* instructions having OE=1 set it to 1 if the carry out of bit M is not equal to the carry out of bit M+1, and set it to 0 otherwise.

XO-form *Multiply Low* and *Divide* instructions having OE=1 set it to 1 if the result cannot be represented in 64 bits (*mulld*, *divd*, *divde*, *divdu*, *divdeu*) or in 32 bits (*mullw*, *divw*, *divdu*, *divwe*, *divwu*, *divweu*), and set it to 0 otherwise. The OV bit is not altered by *Compare* instructions, nor by other instructions (except *mtspr* to the XER, and *mcrxr*) that cannot overflow.

[Category:

Legacy Integer Multiply-Accumulate]

XO-form *Legacy Integer Multiply-Accumulate* instructions set OV when OE=1 to reflect overflow of the 32-bit result. For signed-integer accumulation, overflow occurs when the add produces a carry out of bit 32 that is not equal to the carry out of bit 33. For unsigned-integer accumulation, overflow occurs when the add produces a carry out of bit 32.

34	Carry (CA)
----	-------------------

The Carry bit is set as follows, during execution of certain instructions. *Add Carrying*, *Subtract From Carrying*, *Add Extended*, and *Subtract From Extended* types of instructions set it to 1 if there is a carry out of bit M, and set it to 0 otherwise. *Shift Right Algebraic* instructions set it to 1 if any 1-bits have been shifted out of a negative operand, and set it to 0 otherwise. The CA bit is not altered by *Compare* instructions, nor by other instructions (except *Shift Right Algebraic*, *mtspr* to the XER, and *mcrxr*) that cannot carry.

35:56	Reserved
-------	----------

57:63	This field specifies the number of bytes to be transferred by a <i>Load String Indexed</i> or <i>Store String Indexed</i> instruction.
-------	--

[Category: Legacy Move Assist]

This field is used as a target by *dmlzb* to indicate the byte location of the leftmost zero byte found.

3.2.3 VR Save Register

The VR Save Register (VRSAVE) is a 32-bit register that can be used as a software use SPR; see Sections 3.2.4 and 6.3.3.

Architecture Note

In versions of the Architecture that precede Version 2.05, the VRSAVE Register was in the Vector category (see Section 6.3.3). It is now included in the Base category to simplify operating system support of and migration between heterogeneous systems containing processors with and without support for the Vector category.

access them and does not define the Device Control Registers themselves.

Device Control Registers may control the use of on-chip peripherals, such as memory controllers (the definition of specific Device Control Registers is implementation-dependent).

The contents of user-mode-accessible Device Control Registers can be read using *mfdcrux* and written using *mtdcruw*.

3.2.4 Software Use SPRs [Category: Embedded]

Software Use SPRs are 64-bit registers that have no defined functionality. SPRG4-7 can be read by application programs. Additional Software Use SPRs are defined in Book III.

Figure 47. Software-use SPRs

Programming Note

USPRG0 was made a 32-bit register and renamed to VRSAVE; see Sections 3.2.3 and 6.3.3.

3.2.5 Device Control Registers [Category: Embedded.Device Control]

Device Control Registers (DCRs) are on-chip registers that exist architecturally outside the processor and thus are not actually part of the processor architecture. This specification simply defines the existence of a Device Control Register 'address space' and the instructions to

3.3 Fixed-Point Facility Instructions

3.3.1 Fixed-Point Storage Access Instructions

The *Storage Access* instructions compute the effective address (EA) of the storage to be accessed as described in Section 1.10.3 on page 27.

Programming Note

The *la* extended mnemonic permits computing an effective address as a *Load* or *Store* instruction would, but loads the address itself into a GPR rather than loading the value that is in storage at that address.

Programming Note

The DS field in DS-form *Storage Access* instructions is a word offset, not a byte offset like the D field in D-form *Storage Access* instructions. However, for programming convenience, Assemblers should support the specification of byte offsets for both forms of instruction.

3.3.1.1 Storage Access Exceptions

Storage accesses will cause the system data storage error handler to be invoked if the program is not allowed to modify the target storage (*Store* only), or if the program attempts to access storage that is unavailable.

3.3.2 Fixed-Point Load Instructions

The byte, halfword, word, or doubleword in storage addressed by EA is loaded into register RT.

Many of the *Load* instructions have an “update” form, in which register RA is updated with the effective address. For these forms, if RA≠0 and RA≠RT, the effective address is placed into register RA and the storage element (byte, halfword, word, or doubleword) addressed by EA is loaded into RT.

Programming Note

In some implementations, the *Load Algebraic* and *Load with Update* instructions may have greater latency than other types of *Load* instructions. Moreover, *Load with Update* instructions may take longer to execute in some implementations than the corresponding pair of a non-update *Load* instruction and an *Add* instruction.

Load Byte and Zero**D-form**

lbz RT,D(RA)

0	34	RT	RA	D	31
	6	11	16		

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + EXTS(D)
RT ← 560 || MEM(EA, 1)

```

Let the effective address (EA) be the sum (RA)0+ D. The byte in storage addressed by EA is loaded into RT_{56:63}. RT_{0:55} are set to 0.

Special Registers Altered:

None

Load Byte and Zero with Update **D-form**

lbzu RT,D(RA)

0	35	RT	RA	D	31
	6	11	16		

```

EA ← (RA) + EXTS(D)
RT ← 560 || MEM(EA, 1)
RA ← EA

```

Let the effective address (EA) be the sum (RA)+ D. The byte in storage addressed by EA is loaded into RT_{56:63}. RT_{0:55} are set to 0.

EA is placed into register RA.

If RA=0 or RA=RT, the instruction form is invalid.

Special Registers Altered:

3.3.3 Fixed-Point Store Instructions

The contents of register RS are stored into the byte, halfword, word, or doubleword in storage addressed by EA.

Many of the *Store* instructions have an “update” form, in which register RA is updated with the effective address. For these forms, the following rules apply.

- If $RA \neq 0$, the effective address is placed into register RA.
- If $RS=RA$, the contents of register RS are copied to the target storage element and then EA is placed into RA (RS).

Store Byte

D-form

stb RS,D(RA)

3.3.5 Fixed-Point Load and Store Multiple Instructions

The *Load/Store Multiple* instructions have preferred forms; see Section 1.8.1, “Preferred Instruction Forms” on page 23. In the preferred forms, storage alignment satisfies the following rule.

- The combination of the EA and RT (RS) is such that the low-order byte of GPR 31 is loaded

(stored) from (into) the last byte of an aligned quadword in storage.

For the Server environment, the *Load/Store Multiple* instructions are not supported in Little-Endian mode. If they are executed in Little-Endian mode, the system alignment error handler is invoked.

Load Multiple Word

D-form

lmw RT,D(RA)

```

if RA = 0 then b ← 0
else            b ← (RA)
EA ← b + EXTS(D)
r ← RT
do while r ≤ 31
  GPR(r) ← 320 || MEM(EA, 4)
  r ← r + 1
  EA ← EA + 4

```

Let $n = (32 - RT)$. Let the effective address (EA) be the sum $(RA \ll 0) + D$.

n consecutive words starting at EA are loaded into the low-order 32 bits of GPRs RT through 31. The high-order 32 bits of these GPRs are set to zero.

If RA is in the range of registers to be loaded, including the case in which $RA=0$, the instruction form is invalid.

Special Registers Altered:

None

Store Multiple Word

D-form

stmw RS,D(RA)

```

if RA = 0 then b ← 0
else            b ← (RA)
EA ← b + EXTS(D)
r ← RS
do while r ≤ 31
  MEM(EA, 4) ← GPR(r)32:63
  r ← r + 1
  EA ← EA + 4

```

Let $n = (32 - RS)$. Let the effective address (EA) be the sum $(RA \ll 0) + D$.

n consecutive words starting at EA are stored from the low-order 32 bits of GPRs RS through 31.

Special Registers Altered:

None

3.3.6 Fixed-Point Move Assist Instructions [Category: Move Assist]

The *Move Assist* instructions allow movement of data from storage to registers or from registers to storage without concern for alignment. These instructions can be used for a short move between arbitrary storage locations or to initiate a long move between unaligned storage fields.

The *Load/Store String* instructions have preferred forms; see Section 1.8.1, “Preferred Instruction Forms” on page 23. In the preferred forms, register usage satisfies the following rules.

- RS = 4 or 5

- RT = 4 or 5
- last register loaded/stored ≤ 12

For some implementations, using GPR 4 for RS and RT may result in slightly faster execution than using GPR 5.

For the Server environment, the *Move Assist* instructions are not supported in Little-Endian mode. If they are executed in Little-Endian mode, the system alignment error handler may be invoked or the instructions may be treated as no-ops if the number of bytes specified by the instruction is 0.

3.3.7 Other Fixed-Point Instructions

The remainder of the fixed-point instructions use the contents of the General Purpose Registers (GPRs) as source operands, and place results into GPRs, into the Fixed-Point Exception Register (XER), and into Condition Register fields. In addition, the *Trap* instructions test the contents of a GPR or XER bit, invoking the system trap handler if the result of the specified test is true.

These instructions treat the source operands as signed integers unless the instruction is explicitly identified as performing an unsigned operation.

The X-form and XO-form instructions with Rc=1, and the D-form instructions *addic.*, *andi.*, and *andis.*, set the first three bits of CR Field 0 to characterize the result placed into the target register. In 64-bit mode,

these bits are set by signed comparison of the result to zero. In 32-bit mode, these bits are set by signed comparison of the low-order 32 bits of the result to zero.

Unless otherwise noted and when appropriate, when CR Field 0 and the XER are set they reflect the value placed into the target register.

Programming Note

Instructions with the OE bit set or that set CA may execute slowly or may prevent the execution of subsequent instructions until the instruction has completed.

3.3.8 Fixed-Point Arithmetic Instructions

The XO-form *Arithmetic* instructions with $Rc=1$, and the D-form *Arithmetic* instruction **addic.**, set the first three bits of CR Field 0 as described in Section 3.3.7, “Other Fixed-Point Instructions”.

addic, **addic.**, **subfic**, **addc**, **subfc**, **adde**, **subfe**, **addme**, **subfme**, **addze**, and **subfze** always set CA, to reflect the carry out of bit 0 in 64-bit mode and out of bit 32 in 32-bit mode. The XO-form *Arithmetic* instructions set SO and OV when OE=1 to reflect overflow of the result. Except for the *Multiply Low* and *Divide* instructions, the setting of these bits is mode-dependent, and reflects overflow of the 64-bit result in 64-bit mode and overflow of the low-order 32-bit result in 32-bit mode. For XO-form *Multiply Low* and *Divide* instructions, the setting of these bits is mode-independent, and reflects overflow of the 64-bit result for **mulld**, **divd**, **divde**, **divdu** and **divdeu**, and overflow of the low-order 32-bit result for **mullw**, **divw**, **divwe**, **divwu**, and **divweu**.

Programming Note

Notice that CR Field 0 may not reflect the “true” (infinitely precise) result if overflow occurs.

Extended mnemonics for addition and subtraction

Several extended mnemonics are provided that use the *Add Immediate* and *Add Immediate Shifted* instructions to load an immediate value or an address into a target register. Some of these are shown as examples with the two instructions.

The Power ISA supplies *Subtract From* instructions, which subtract the second operand from the third. A set of extended mnemonics is provided that use the more “normal” order, in which the third operand is subtracted from the second, with the third operand being either an immediate field or a register. Some of these are shown as examples with the appropriate *Add* and *Subtract From* instructions.

See Appendix E for additional extended mnemonics.

Add Immediate

 $RT_{32:63} \leftarrow dividend \div divisor$
 $RT_{0:31} \leftarrow undefined$

The 64-bit dividend is $(RA)_{32:63} \parallel 32_0$. The 32-bit divisor is $(RB)_{32:63}$. If the quotient can be represented in 32 bits, it is placed into $RT_{32:63}$. The contents of $RT_{0:31}$ are undefined. The remainder is not supplied as a result.

Both operands and the quotient are interpreted as signed integers. The quotient is the unique signed integer that satisfies

$$dividend = (quotient \times divisor) + r$$

where $0 \leq r < |divisor|$ if the dividend is nonnegative, and $-|divisor| < r \leq 0$ if the dividend is negative.

If the quotient cannot be represented in 32 bits, or if an attempt is made to perform the division

$\langle anything \rangle \div 0$

then the contents of register RT are undefined as are (if $Rc=1$) the contents of the LT, GT, and EQ bits of CR Field 0. In these cases, if $OE=1$ then OV is set to 1.

Special Registers Altered:

CR0 (bits 0:2 undefined in 64-bit mode) (if $Rc=1$)
 SO OV (if $OE=1$)

Divide Word Extended Unsigned XO-form

divweu RT,RA,RB (OE=0 Rc=0)
 divweu. RT,RA,RB (OE=0 Rc=1)
 divweuo RT,RA,RB (OE=1 Rc=0)
 divweuo. RT,RA,RB (OE=1 Rc=1)

[Category: Server]

[Category: Embedded.Phased-In]

31	RT	RA	RB	OE	395	Rc
0	6	11	16	21	22	31

$dividend_{0:63} \leftarrow (RA)_{32:63} \parallel 32_0$
 $divisor_{0:31} \leftarrow (RB)_{32:63}$
 $RT_{32:63} \leftarrow dividend \div divisor$
 $RT_{0:31} \leftarrow undefined$

The 64-bit dividend is $(RA)_{32:63} \parallel 32_0$. The 32-bit divisor is $(RB)_{32:63}$. If the quotient can be represented in 32 bits, it is placed into $RT_{32:63}$. The contents of $RT_{0:31}$ are undefined. The remainder is not supplied as a result.

Both operands and the quotient are interpreted as unsigned integers, except that if $Rc=1$ the first three bits of CR Field 0 are set by signed comparison of the result to zero. The quotient is the unique unsigned integer that satisfies

$$dividend = (quotient \times divisor) + r$$

where $0 \leq r < divisor$.

If $(RA) \geq (RB)$, or if an attempt is made to perform the division

$\langle anything \rangle \div 0$

then the contents of register RT are undefined as are (if $Rc=1$) the contents of the LT, GT, and EQ bits of CR Field 0. In these cases, if $OE=1$ then OV is set to 1.

Special Registers Altered:

CR0 (bits 0:2 undefined in 64-bit mode) (if $Rc=1$)
 SO OV (if $OE=1$)

Programming Note

Unsigned long division of a 64-bit dividend contained in two 32-bit registers by a 32-bit divisor can be computed as follows. The algorithm is shown first, followed by Assembler code that implements the algorithm. The dividend is Dh || Dl, the divisor is Dv, and the quotient and remainder are Q and R respectively, where these variables and all intermediate variables represent unsigned 32-bit integers. It is assumed that $Dv > Dh$, and that assigning a value to an intermediate variable assigns the low-order 32 bits of the value and ignores any higher-order bits of the value. (In both the algorithm and the Assembler code, “r1” and “r2” refer to “remainder 1” and “remainder 2”, rather than to GPRs 1 and 2.)

Algorithm:

3. $q1 \leftarrow \text{divweu } Dh, Dv$
4. $r1 \leftarrow -(q1 \times Dv)$ # remainder of step 1
 divide operation
 (see Note 1)
5. $q2 \leftarrow \text{divwu } Dl, Dv$
6. $r2 \leftarrow Dl - (q2 \times Dv)$ # remainder of step 2
 divide operation
7. $Q \leftarrow q1 + q2$
8. $R \leftarrow r1 + r2$
9. if $(R < r2) \vee (R \geq Dv)$ then # (see Note 2)
 - $Q \leftarrow Q + 1$ # increment quotient
 - $R \leftarrow R - Dv$ # decrement rem'der

Assembler Code:

```
# Dh in r4, Dl in r5
# Dv in r6
divweu r3,r4,r6    # q1
divwu  r7,r5,r6    # q2
mullw  r8,r3,r6    # -r1 = q1 * Dv
mullw  r0,r7,r6    # q2 * Dv
subf   r10,r0,r5   # r2 = Dl - (q2 * Dv)
add    r3,r3,r7    # Q = q1 + q2
subf   r4,r8,r10   # R = r1 + r2
cmplw  r4,r10     # R < r2 ?
blt    *+12       # must adjust Q and R if yes
cmplw  r4,r6      # R ≥ Dv ?
blt    *+12       # must adjust Q and R if yes
addi   r3,r3,1    # Q = Q + 1
subf   r4,r6,r4   # R = R - Dv
# Quotient in r3
# Remainder in r4
```

Notes:

1. The remainder is $Dh \parallel^{32} 0 - (q1 \times Dv)$. Because the remainder must be less than Dv and $Dv < 2^{32}$, the remainder is representable in 32 bits. Because the low-order 32 bits of $Dh \parallel^{32} 0$ are 0s, the remainder is therefore equal to the low-order 32 bits of $-(q1 \times Dv)$. Thus assigning $-(q1 \times Dv)$ to r1 yields the correct remainder.
2. R is less than r2 (and also less than r1) if and only if the addition at step 6 carried out of 32 bits — i.e., if and only if the correct sum could not be represented in 32 bits — in which case the correct sum is necessarily greater than Dv .
3. For additional information see the book *Hacker's Delight*, by Henry S. Warren, Jr., as potentially amended at the web site <http://www.hackersdelight.org>.

3.3.8.1 64-bit Fixed-Point Arithmetic Instructions [Category: 64-Bit]

Multiply Low Doubleword

XO-form

mulld RT,RA,RB (OE=0 Rc=0)
 mulld. RT,RA,RB (OE=0 Rc=1)
 mulldo RT,RA,RB (OE=1 Rc=0)
 mulldo. RT,RA,RB (OE=1 Rc=1)

31	RT	RA	RB	OE	233	Rc
0	6	11	16	21	22	31

$prod_{0:127} \leftarrow (RA) \times (RB)$
 $RT \leftarrow prod_{64:127}$

The 64-bit operands are (RA) and (RB). The low-order 64 bits of the 128-bit product of the operands are placed into register RT.

If OE=1 then OV is set to 1 if the product cannot be represented in 64 bits.

Both operands and the product are interpreted as signed integers.

Special Registers Altered:

CR0 (if Rc=1)
 SO OV (if OE=1)

Programming Note

The *XO-form Multiply* instructions may execute faster on some implementations if RB contains the operand having the smaller absolute value.

Multiply High Doubleword

XO-form

mulhd RT,RA,RB (Rc=0)
 mulhd. RT,RA,RB (Rc=1)

31	RT	RA	RB	/	73	Rc
0	6	11	16	21	22	31

$prod_{0:127} \leftarrow (RA) \times (RB)$
 $RT \leftarrow prod_{0:63}$

The 64-bit operands are (RA) and (RB). The high-order 64 bits of the 128-bit product of the operands are placed into register RT.

Both operands and the product are interpreted as signed integers.

Special Registers Altered:

CR0 (if Rc=1)

Multiply High Doubleword Unsigned

XO-form

mulhdu RT,RA,RB (Rc=0)
 mulhdu. RT,RA,RB (Rc=1)

31	RT	RA	RB	/	9	Rc
0	6	11	16	21	22	31

$prod_{0:127} \leftarrow (RA) \times (RB)$
 $RT \leftarrow prod_{0:63}$

The 64-bit operands are (RA) and (RB). The high-order 64 bits of the 128-bit product of the operands are placed into register RT.

Both operands and the product are interpreted as unsigned integers, except that if Rc=1 the first three bits of CR Field 0 are set by signed comparison of the result to zero.

Special Registers Altered:

CR0 (if Rc=1)

Divide Doubleword**XO-form**

divd	RT,RA,RB	(OE=0 Rc=0)
divd.	RT,RA,RB	(OE=0 Rc=1)
divdo	RT,RA,RB	(OE=1 Rc=0)
divdo.	RT,RA,RB	(OE=1 Rc=1)

31	RT	RA	RB	OE	489	Rc
0	6	11	16	21	22	31

dividend_{0:63} ← (RA)
 divisor_{0:63} ← (RB)
 RT ← dividend ÷ divisor

The 64-bit dividend is (RA). The 64-bit divisor is (RB).
 The 64-bit quotient is placed into register RT. The remainder is not supplied as a result.

Both operands and the quotient are interpreted as signed integers. The quotient is the unique signed integer that satisfies

$$\text{dividend} = (\text{quotient} \times \text{divisor}) + r$$

where $0 \leq r < |\text{divisor}|$ if the dividend is nonnegative, and $-|\text{divisor}| < r \leq 0$ if the dividend is negative.

If an attempt is made to perform any of the divisions

```
0x8000_0000_0000_0000 ÷ -1
<anything> ÷ 0
```

then the contents of register RT are undefined as are (if Rc=1) the contents of the LT, GT, and EQ bits of CR Field 0. In these cases, if OE=1 then OV is set to 1.

Special Registers Altered:

CR0 (if Rc=1)
 SO OV (if OE=1)

Programming Note

The 64-bit signed remainder of dividing (RA) by (RB) can be computed as follows, except in the case that (RA) = -2^{63} and (RB) = -1.

```
divd RT,RA,RB # RT = quotient
mulld RT,RT,RB # RT = quotient×divisor
subf RT,RT,RA # RT = remainder
```

Divide Doubleword Unsigned**XO-form**

divdu	RT,RA,RB	(OE=0 Rc=0)
divdu.	RT,RA,RB	(OE=0 Rc=1)
divduo	RT,RA,RB	(OE=1 Rc=0)
divduo.	RT,RA,RB	(OE=1 Rc=1)

0	6	11	16	21	22	31

dividend_{0:63} ← (RA)
 divisor_{0:63} ← (RB)
 RT ← dividend ÷ divisor

The 64-bit dividend is (RA). The 64-bit divisor is (RB).
 The 64-bit quotient is placed into register RT. The remainder is not supplied as a result.

Both operands and the quotient are interpreted as unsigned integers, except that if Rc=1 the first three bits of CR Field 0 are set by signed comparison of the result to zero. The quotient is the unique unsigned integer that satisfies

$$\text{dividend} = (\text{quotient} \times \text{divisor}) + r$$

where $0 \leq r < \text{divisor}$.

If an attempt is made to perform the division

```
<anything> ÷ 0
```

then the contents of register RT are undefined as are (if Rc=1) the contents of the LT, GT, and EQ bits of CR Field 0. In this case, if OE=1 then OV is set to 1.

Special Registers Altered:

CR0 (if Rc=1)
 SO OV (if OE=1)

Programming Note

The 64-bit unsigned remainder of dividing (RA) by (RB) can be computed as follows.

```
divdu RT,RA,RB # RT = quotient
mulld RT,RT,RB # RT = quotient×divisor
subf RT,RT,RA # RT = remainder
```

Divide Doubleword Extended XO-form

0	6	11	16	21	22	31

$\text{dividend}_{0:127} \leftarrow (\text{RA}) \parallel 64_0$
 $\text{divisor}_{0:63} \leftarrow (\text{RB})$
 $\text{RT} \leftarrow \text{dividend} \div \text{divisor}$

The 128-bit dividend is (RA) || 64_0 . The 64-bit divisor is (RB). If the quotient can be represented in 64 bits, it is placed into register RT. The remainder is not supplied as a result.

Both operands and the quotient are interpreted as unsigned integers, except that if Rc=1 the first three bits of CR Field 0 are set by signed comparison of the result to zero. The quotient is the unique unsigned integer that satisfies

$$\text{dividend} = (\text{quotient} \times \text{divisor}) + r$$

where $0 \leq r < \text{divisor}$.

If (RA) \geq (RB), or if an attempt is made to perform the division

<anything> $\div 0$

then the contents of register RT are undefined as are (if Rc=1) the contents of the LT, GT, and EQ bits of CR Field 0. In these cases, if OE=1 then OV is set to 1.

Special Registers Altered:

CR0 (if Rc=1)
 SO OV (if OE=1)

Programming Note

Unsigned long division of a 128-bit dividend contained in two 64-bit registers by a 64-bit divisor can be accomplished using the technique described in the Programming Note with the *divweu* instruction description: *divd[e]u* would be used instead of *divw[e]u* (and *cmpld* instead of *cmplw*, etc.).

3.3.9 Fixed-Point Compare Instructions

The fixed-point *Compare* instructions compare the contents of register RA with (1) the sign-extended value of the SI field, (2) the zero-extended value of the UI field, or (3) the contents of register RB. The comparison is signed for *cmpi* and *cmp*, and unsigned for *cmpui* and *cmpil*.

The L field controls whether the operands are treated as 64-bit or 32-bit quantities, as follows:

L	Operand length
0	32-bit operands
1	64-bit operands

L=1 is part of Category: 64-Bit.

When the operands are treated as 32-bit signed quantities, bit 32 of the register (RA or RB) is the sign bit.

The *Compare* instructions set one bit in the leftmost three bits of the designated CR field to 1, and the other

two to 0. XER_{SO} is copied to bit 3 of the designated CR field.

The CR field is set as follows

Bit	Name	Description
0	LT	(RA) < SI or (RB) (signed comparison) (RA) < ^u UI or (RB) (unsigned comparison)
1	GT	(RA) > SI or (RB) (signed comparison) (RA) > ^u UI or (RB) (unsigned comparison)
2	EQ	(RA) = SI, UI, or (RB)
3	SO	Summary Overflow from the XER

Extended mnemonics for compares

A set of extended mnemonics is provided so that compares can be coded with the operand length as part of the mnemonic rather than as a numeric operand. Some of these are shown as examples with the *Compare* instructions. See Appendix E for additional extended mnemonics.

Compare Immediate

D-form

cmpi BF,L,RA,SI

11	BF	/	L	RA	SI
0	6	9	10	11	16
					31

```
if L = 0 then a ← EXTS((RA)32:63)
    else a ← (RA)
if a < EXTS(SI) then c ← 0b100
else if a > EXTS(SI) then c ← 0b010
else c ← 0b001
CR4×BF+32:4×BF+35 ← c || XERSO
```

The contents of register RA ((RA)_{32:63} sign-extended to 64 bits if L=0) are compared with the sign-extended value of the SI field, treating the operands as signed integers. The result of the comparison is placed into CR field BF.

Special Registers Altered:

CR field BF

Extended Mnemonics:

Examples of extended mnemonics for Compare Immediate:

Extended:	Equivalent to:
cmpld Rx,Ry	cmpl 0,1,Rx,Ry
cmplw cr3,Rx,Ry	cmpl 3,0,Rx,Ry

3.3.10 Fixed-Point Trap Instructions

The *Trap* instructions are provided to test for a specified set of conditions. If any of the conditions tested by a *Trap* instruction are met, the system trap handler is invoked. If none of the tested conditions are met, instruction execution continues normally.

The contents of register RA are compared with either the sign-extended value of the SI field or the contents of register RB, depending on the *Trap* instruction. For *tdi* and *td*, the entire contents of RA (and RB) participate in the comparison; for *twi* and *tw*, only the contents of the low-order 32 bits of RA (and RB) participate in the comparison.

This comparison results in five conditions which are ANDed with TO. If the result is not 0 the system trap handler is invoked. These conditions are as follows.

TO Bit ANDed with Condition

0	Less Than, using signed comparison
1	Greater Than, using signed comparison
2	Equal
3	Less Than, using unsigned comparison
4	Greater Than, using unsigned comparison

Extended mnemonics for traps

A set of extended mnemonics is provided so that traps can be coded with the condition as part of the mnemonic rather than as a numeric operand. Some of these are shown as examples with the Trap instructions. See Appendix E for additional extended mnemonics.

Trap Word Immediate

D-form

twi TO,RA,SI

0	3	TO	RA	SI	31
	6		11	16	

```
a ← EXTS((RA)32:63)
if (a < EXTS(SI)) & TO0 then TRAP
if (a > EXTS(SI)) & TO1 then TRAP
if (a = EXTS(SI)) & TO2 then TRAP
if (a <u EXTS(SI)) & TO3 then TRAP
if (a >u EXTS(SI)) & TO4 then TRAP
```

The contents of RA_{32:63} are compared with the sign-extended value of the SI field. If any bit in the TO field is set to 1 and its corresponding condition is met by the result of the comparison, the system trap handler is invoked.

If the trap conditions are met, this instruction is context synchronizing (see Book III).

Special Registers Altered:

None

Extended Mnemonics:

Examples of extended mnemonics for *Trap Word Immediate*:

Extended:	Equivalent to:
twgti Rx,value	twi 8,Rx,value
twlei Rx,value	twi 6,Rx,value

Trap Word

X-form

tw TO,RA,RB

0	31	TO	RA	RB	4	/	31
	6		11	16	21		

```
a ← EXTS((RA)32:63)
b ← EXTS((RB)32:63)
if (a < b) & TO0 then TRAP
if (a > b) & TO1 then TRAP
if (a = b) & TO2 then TRAP
if (a <u b) & TO3 then TRAP
if (a >u b) & TO4 then TRAP
```

The contents of RA_{32:63} are compared with the contents of RB_{32:63}. If any bit in the TO field is set to 1 and its corresponding condition is met by the result of the comparison, the system trap handler is invoked.

If the trap conditions are met, this instruction is context synchronizing (see Book III).

Special Registers Altered:

None

Extended Mnemonics:

Examples of extended mnemonics for *Trap Word*:

Extended:	Equivalent to:
tweq Rx,Ry	tw 4,Rx,Ry
twlge Rx,Ry	tw 5,Rx,Ry
trap	tw 31,0,0

3.3.10.1 64-bit Fixed-Point Trap Instructions [Category: 64-Bit]

Trap Doubleword Immediate *D-form*

tdi TO,RA,SI

0	2	TO	RA	SI	31
	6	11	16		

```

a ← (RA)
b ← EXTS(SI)
if (a < b) & TO0 then TRAP
if (a > b) & TO1 then TRAP
if (a = b) & TO2 then TRAP
if (a <u b) & TO3 then TRAP
if (a >u b) & TO4 then TRAP

```

The contents of register RA are compared with the sign-extended value of the SI field. If any bit in the TO field is set to 1 and its corresponding condition is met by the result of the comparison, the system trap handler is invoked.

If the trap conditions are met, this instruction is context synchronizing (see Book III).

Special Registers Altered:

None

Extended Mnemonics:

Examples of extended mnemonics for *Trap Doubleword Immediate*:

Extended:	Equivalent to:
tdlti Rx,value	tdi 16,Rx,value
tdnei Rx,value	tdi 24,Rx,value

Trap Doubleword *X-form*

td TO,RA,RB

0	31	TO	RA	RB	68	/	31
	6	11	16	21			

```

a ← (RA)
b ← (RB)
if (a < b) & TO0 then TRAP
if (a > b) & TO1 then TRAP
if (a = b) & TO2 then TRAP
if (a <u b) & TO3 then TRAP
if (a >u b) & TO4 then TRAP

```

The contents of register RA are compared with the contents of register RB. If any bit in the TO field is set to 1 and its corresponding condition is met by the result of the comparison, the system trap handler is invoked.

If the trap conditions are met, this instruction is context synchronizing (see Book III).

Special Registers Altered:

None

Extended Mnemonics:

Examples of extended mnemonics for *Trap Doubleword*:

Extended:	Equivalent to:
tdge Rx,Ry	td 12,Rx,Ry
tdlnl Rx,Ry	td 5,Rx,Ry

3.3.11 Fixed-Point Select [Category: Phased-In (sV2.06)]

Integer Select *A-form*

isel RT,RA,RB,BC

0	31	RT	RA	RB	BC	15	/	31
	6	11	16	21	26			

```

if RA=0 then a ← 0 else a ← (RA)
if CRBC+32=1 then RT ← a
else RT ← (RB)

```

If the contents of bit BC+32 of the Condition Register are equal to 1, then the contents of register RA (or 0) are placed into register RT. Otherwise, the contents of register RB are placed into register RT.

Special Registers Altered:

None

3.3.12 Fixed-Point Logical Instructions

The *Logical* instructions perform bit-parallel operations on 64-bit operands.

The X-form Logical instructions with Rc=1, and the D-form *Logical* instructions *andi.* and *andis.*, set the first three bits of CR Field 0 as described in Section 3.3.7, “Other Fixed-Point Instructions” on page 61. The Logical instructions do not change the SO, OV, and CA bits in the XER.

Extended mnemonics for logical operations

Extended mnemonics are provided that generate two different types of “no-ops” (instructions that do nothing). The first type is the preferred form, which is optimized to minimize its use of the processor's execution

resources. This form is based on the *OR Immediate* instruction. The second type is the executed form, which is intended to consume the same amount of the processor's execution resources as if it were not a no-op. This form is based on the *XOR Immediate* instruction. (There are also no-ops which affect program priority, for which extended mnemonics have not been assigned.)

Extended mnemonics are provided that use the *OR* and *NOR* instructions to copy the contents of one register to another, with and without complementing. These are shown as examples with the two instructions.

See Appendix E, “Assembler Extended Mnemonics” on page 627 for additional extended mnemonics.

AND Immediate

D-form

andi. RA,RS,UI

$$RA \leftarrow (RS) \& (^{48}0 \parallel UI)$$

The contents of register RS are ANDed with $^{48}0 \parallel UI$ and the result is placed into register RA.

Special Registers Altered:

CR0

AND Immediate Shifted

D-form

andis. RA,RS,UI

$$RA \leftarrow (RS) \& (^{32}0 \parallel UI \parallel ^{16}0)$$

The contents of register RS are ANDed with $^{32}0 \parallel UI \parallel ^{16}0$ and the result is placed into register RA.

Special Registers Altered:

CR0

OR Immediate

D-form

ori RA,RS,UI

$$RA \leftarrow (RS) \mid (^{48}0 \parallel UI)$$

The contents of register RS are ORed with $^{48}0 \parallel UI$ and the result is placed into register RA.

The preferred “no-op” (an instruction that does nothing) is:

ori 0,0,0

Special Registers Altered:

None

Extended Mnemonics:

Example of extended mnemonics for *OR Immediate*:

Extended:

no-op

Equivalent to:

ori 0,0,0

OR Immediate Shifted**D-form**

oris RA,RS,UI

25	RS	RA	UI
0	6	11	16
31			

$$RA \leftarrow (RS) \mid (^{32}0 \parallel UI \parallel ^{16}0)$$

The contents of register RS are ORed with $^{32}0 \parallel UI \parallel ^{16}0$ and the result is placed into register RA.

Special Registers Altered:

None

XOR Immediate**D-form**

xori RA,RS,UI

26	RS	RA	UI
0	6	11	16
31			

$$RA \leftarrow (RS) \text{ XOR } (^{48}0 \parallel UI)$$

The contents of register RS are XORed with $^{48}0 \parallel UI$ and the result is placed into register RA.

The executed form of a “no-op” (an instruction that does nothing, but consumes execution resources nevertheless) is:

```
xori 0,0,0
```

Special Registers Altered:

None

Extended Mnemonics:

Example of extended mnemonics for *XOR Immediate*:

Extended:	Equivalent to:
xnop	xori 0,0,0

Programming Note

The executed form of no-op should be used only when the intent is to alter the timing of a program.

XOR Immediate Shifted**D-form**

xoris RA,RS,UI

27	RS	RA	UI
0	6	11	16
31			

$$RA \leftarrow (RS) \text{ XOR } (^{32}0 \parallel UI \parallel ^{16}0)$$

The contents of register RS are XORed with $^{32}0 \parallel UI \parallel ^{16}0$ and the result is placed into register RA.

Special Registers Altered:

None

  n ← 0
  do j = 0 to 7
    if (RS)(i×8)+j = 1 then
      n ← n+1
  RA(i×8):(i×8)+7 ← n

```

A count of the number of one bits in each byte of register RS is placed into the corresponding byte of register RA. This number ranges from 0 to 8, inclusive.

Special Registers Altered:

None

Population Count Words**X-form**

popcntw RA, RS

[Category: Server]

[Category: Embedded.Phased-In]

31	RS	RA	///	378	/
0	6	11	16	21	31

```

do i = 0 to 1
  n ← 0
  do j = 0 to 31
    if (RS)(i×32)+j = 1 then
      n ← n+1
  RA(i×32):(i×32)+31 ← n

```

A count of the number of one bits in each word of register RS is placed into the corresponding word of register RA. This number ranges from 0 to 32, inclusive.

Special Registers Altered:

None

Parity Doubleword**X-form**

prtyd RA,RS
 [Category: 64-bit]

31	RS	RA	///	186	/
0	6	11	16	21	31

```

s ← 0
do i = 0 to 7
  s ← s ⊕ (RS)i×8+7
RA ← 630 || s
  
```

The least significant bit in each byte of the contents of register RS is examined. If there is an odd number of one bits the value 1 is placed into register RA; otherwise the value 0 is placed into register RA.

Special Registers Altered:

None

Parity Word**X-form**

prtyw RA,RS

31	RS	RA	///	154	/
0	6	11	16	21	31

```

s ← 0
t ← 0
do i = 0 to 3
  s ← s ⊕ (RS)i×8+7
do i = 4 to 7
  t ← t ⊕ (RS)i×8+7
RA0:31 ← 310 || s
RA32:63 ← 310 || t
  
```

The least significant bit in each byte of (RS)_{0:31} is examined. If there is an odd number of one bits the value 1 is placed into RA_{0:31}; otherwise the value 0 is placed into RA_{0:31}. The least significant bit in each byte of (RS)_{32:63} is examined. If there is an odd number of one bits the value 1 is placed into RA_{32:63}; otherwise the value 0 is placed into RA_{32:63}.

Special Registers Altered:

None

Programming Note

The *Parity* instructions are designed to be used in conjunction with the *Population Count* instruction to compute the parity of words or a doubleword. The parity of the upper and lower words in (RS) can be computed as follows.

```

popcntb RA, RS
prtyw RA, RA
  
```

The parity of (RS) can be computed as follows.

```

popcntb RA, RS
prtyd RA, RA
  
```

3.3.12.1 64-bit Fixed-Point Logical Instructions [Category: 64-Bit]

Extend Sign Word

X-form

extsw RA,RS (Rc=0)
extsw. RA,RS (Rc=1)

0	31	RS	RA	///	986	Rc
	6	11	16	21		31

$s \leftarrow (RS)_{32}$
 $RA_{32:63} \leftarrow (RS)_{32:63}$
 $RA_{0:31} \leftarrow {}^{32}s$

$(RS)_{32:63}$ are placed into $RA_{32:63}$. $RA_{0:31}$ are filled with a copy of $(RS)_{32}$.

Special Registers Altered:

CR0 (if Rc=1)

Count Leading Zeros Doubleword *X-form*

cntlzd RA,RS (Rc=0)
cntlzd. RA,RS (Rc=1)

0	31	RS	RA	///	58	Rc
	6	11	16	21		31

$n \leftarrow 0$
do while $n < 64$
 if $(RS)_n = 1$ then leave
 $n \leftarrow n + 1$
 $RA \leftarrow n$

A count of the number of consecutive zero bits starting at bit 0 of register RS is placed into register RA. This number ranges from 0 to 64, inclusive.

If Rc=1, CR Field 0 is set to reflect the result.

Special Registers Altered:

CR0 (if Rc=1)

Population Count Doubleword *X-form*

popcntd RA,RS
[Category: Server.64-bit]
[Category: Embedded.64-bit.Phased-In]

0	31	RS	RA	///	506	/
	6	11	16	21		31

$n \leftarrow 0$
do $i = 0$ to 63
 if $(RS)_i = 1$ then
 $n \leftarrow n + 1$
 $RA \leftarrow n$

A count of the number of one bits in register RS is placed into register RA. This number ranges from 0 to 64, inclusive.

Special Registers Altered:

None

Bit Permute Doubleword**X-form**

bpermd RA,RS,RB

[Category: Embedded.Phased-in, Server]

31	RS	RA	RB	252	/
0	6	11	16	21	31

```

For i = 0 to 7
  index ← (RS)8*i:8*i+7
  If index < 64
    then permi ← (RB)index
    else permi ← 0
RA ← 560 || perm0:7

```

Eight permuted bits are produced. For each permuted bit i where i ranges from 0 to 7 and for each byte i of RS, do the following.

If byte i of RS is less than 64, permuted bit i is set to the bit of RB specified by byte i of RS; otherwise permuted bit i is set to 0.

The permuted bits are placed in the least-significant byte of RA, and the remaining bits are filled with 0s.

Special Registers Altered:

None

Programming Note

The fact that the permuted bit is 0 if the corresponding index value exceeds 63 permits the permuted bits to be selected from a 128-bit quantity, using a single index register. For example, assume that the 128-bit quantity Q , from which the permuted bits are to be selected, is in registers $r2$ (high-order 64 bits of Q) and $r3$ (low-order 64 bits of Q), that the index values are in register $r1$, with each byte of $r1$ containing a value in the range 0:127, and that each byte of register $r4$ contains the value 64. The following code sequence selects eight permuted bits from Q and places them into the low-order byte of $r6$.

```

bpermd  r6,r1,r2    # select from high-
                    # order half of Q
xor     r0,r1,r4    # adjust index values
bpermd  r5,r0,r3    # select from low-
                    # order half of Q
or      r6,r6,r5    # merge the two
                    # selections

```

3.3.13 Fixed-Point Rotate and Shift Instructions

The Fixed-Point Facility performs rotation operations on data from a GPR and returns the result, or a portion of the result, to a GPR.

The rotation operations rotate a 64-bit quantity left by a specified number of bit positions. Bits that exit from position 0 enter at position 63.

Two types of rotation operation are supported.

For the first type, denoted rotate_{64} or ROTL_{64} , the value rotated is the given 64-bit value. The rotate_{64} operation is used to rotate a given 64-bit quantity.

For the second type, denoted rotate_{32} or ROTL_{32} , the value rotated consists of two copies of bits 32:63 of the given 64-bit value, one copy in bits 0:31 and the other in bits 32:63. The rotate_{32} operation is used to rotate a given 32-bit quantity.

The *Rotate* and *Shift* instructions employ a mask generator. The mask is 64 bits long, and consists of 1-bits from a start bit, *mstart*, through and including a stop bit, *mstop*, and 0-bits elsewhere. The values of *mstart* and *mstop* range from 0 to 63. If *mstart* > *mstop*, the 1-bits wrap around from position 63 to position 0. Thus the mask is formed as follows:

```

if mstart ≤ mstop then
    maskmstart:mstop = ones
    maskall other bits = zeros
else
    maskmstart:63 = ones
    mask0:mstop = ones
    maskall other bits = zeros

```

There is no way to specify an all-zero mask.

For instructions that use the rotate_{32} operation, the mask start and stop positions are always in the low-order 32 bits of the mask.

The use of the mask is described in following sections.

The *Rotate* and *Shift* instructions with $Rc=1$ set the first three bits of CR field 0 as described in Section 3.3.7, “Other Fixed-Point Instructions” on page 61. *Rotate* and *Shift* instructions do not change the OV and SO bits. *Rotate* and *Shift* instructions, except algebraic right shifts, do not change the CA bit.

Extended mnemonics for rotates and shifts

The *Rotate* and *Shift* instructions, while powerful, can be complicated to code (they have up to five operands). A set of extended mnemonics is provided that allow simpler coding of often-used functions such as clearing the leftmost or rightmost bits of a register, left justifying or right justifying an arbitrary field, and performing simple rotates and shifts. Some of these are shown as examples with the *Rotate* instructions. See Appendix E, “Assembler Extended Mnemonics” on page 627 for additional extended mnemonics.

3.3.13.1 Fixed-Point Rotate Instructions

These instructions rotate the contents of a register. The result of the rotation is

- inserted into the target register under control of a mask (if a mask bit is 1 the associated bit of the rotated data is placed into the target register, and if the mask bit is 0 the associated bit in the target register remains unchanged); or
- ANDed with a mask before being placed into the target register.

The *Rotate Left* instructions allow right-rotation of the contents of a register to be performed (in concept) by a left-rotation of $64-n$, where n is the number of bits by which to rotate right. They allow right-rotation of the contents of the low-order 32 bits of a register to be performed (in concept) by a left-rotation of $32-n$, where n is the number of bits by which to rotate right.

Rotate Left Word Immediate then AND with Mask M-form

rlwinm RA,RS,SH,MB,ME ($Rc=0$)
 rlwinm. RA,RS,SH,MB,ME ($Rc=1$)

21	RS	RA	SH	MB	ME	Rc
0	6	11	16	21	26	31

```

n ← SH
r ← ROTL32((RS)32:63, n)
m ← MASK(MB+32, ME+32)
RA ← r & m

```

The contents of register RS are rotated₃₂ left SH bits. A mask is generated having 1-bits from bit MB+32 through bit ME+32 and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register RA.

Special Registers Altered:

CRO (if $Rc=1$)

Extended Mnemonics:

Examples of extended mnemonics for *Rotate Left Word Immediate then AND with Mask*:

Extended:		Equivalent to:	
extlwi	Rx,Ry,n,b	rlwinm	Rx,Ry,b,0,n-1
srwi	Rx,Ry,n	rlwinm	Rx,Ry,32-n,n,3 1
clrrwi	Rx,Ry,n	rlwinm	Rx,Ry,0,0,31-n

Programming Note

Let RSL represent the low-order 32 bits of register RS, with the bits numbered from 0 through 31.

rlwinm can be used to extract an n-bit field that starts at bit position b in RSL, right-justified into the low-order 32 bits of register RA (clearing the remaining 32-n bits of the low-order 32 bits of RA), by setting SH=b+n, MB=32-n, and ME=31. It can be used to extract an n-bit field that starts at bit position b in RSL, left-justified into the low-order 32 bits of register RA (clearing the remaining 32-n bits of the low-order 32 bits of RA), by setting SH=b, MB=0, and ME=n-1. It can be used to rotate the contents of the low-order 32 bits of a register left (right) by n bits, by setting SH=n (32-n), MB=0, and ME=31. It can be used to shift the contents of the low-order 32 bits of a register right by n bits, by setting SH=32-n, MB=n, and ME=31. It can be used to clear the high-order b bits of the low-order 32 bits of the contents of a register and then shift the result left by n bits, by setting SH=n, MB=b-n, and ME=31-n. It can be used to clear the low-order n bits of the low-order 32 bits of a register, by setting SH=0, MB=0, and ME=31-n.

For all the uses given above, the high-order 32 bits of register RA are cleared.

Extended mnemonics are provided for all of these uses; see Appendix E, "Assembler Extended Mnemonics" on page 627.

Rotate Left Word then AND with Mask
M-form

rlwnm	RA,RS,RB,MB,ME	(Rc=0)
rlwnm.	RA,RS,RB,MB,ME	(Rc=1)

23	RS	RA	RB	MB	ME	Rc
0	6	11	16	21	26	31

$n \leftarrow (RB)_{59:63}$
 $r \leftarrow ROTL_{32}((RS)_{32:63}, n)$
 $m \leftarrow MASK(MB+32, ME+32)$
 $RA \leftarrow r \& m$

The contents of register RS are rotated₃₂ left the number of bits specified by (RB)_{59:63}. A mask is generated having 1-bits from bit MB+32 through bit ME+32 and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register RA.

Special Registers Altered:

CR0 (if Rc=1)

Extended Mnemonics:

Example of extended mnemonics for *Rotate Left Word then AND with Mask*:

Extended:		Equivalent to:	
rotlwi	Rx,Ry,Rz	rlwnm	Rx,Ry,Rz,0,31

Programming Note

Let RSL represent the low-order 32 bits of register RS, with the bits numbered from 0 through 31.

rlwnm can be used to extract an n-bit field that starts at variable bit position b in RSL, right-justified into the low-order 32 bits of register RA (clearing the remaining 32-n bits of the low-order 32 bits of RA), by setting $RB_{59:63}=b+n$, MB=32-n, and ME=31. It can be used to extract an n-bit field that starts at variable bit position b in RSL, left-justified into the low-order 32 bits of register RA (clearing the remaining 32-n bits of the low-order 32 bits of RA), by setting $RB_{59:63}=b$, MB=0, and ME=n-1. It can be used to rotate the contents of the low-order 32 bits of a register left (right) by variable n bits, by setting $RB_{59:63}=n$ (32-n), MB=0, and ME=31.

For all the uses given above, the high-order 32 bits of register RA are cleared.

Extended mnemonics are provided for some of these uses; see Appendix E, "Assembler Extended Mnemonics" on page 627.

Rotate Left Word Immediate then Mask Insert **M-form**

rlwimi RA,RS,SH,MB,ME (Rc=0)
rlwimi. RA,RS,SH,MB,ME (Rc=1)

20	RS	RA	SH	MB	ME	Rc
0	6	11	16	21	26	31

$n \leftarrow SH$
 $r \leftarrow ROTL_{32}((RS)_{32:63}, n)$
 $m \leftarrow MASK(MB+32, ME+32)$
 $RA \leftarrow r \& m \mid (RA) \& \neg m$

The contents of register RS are rotated₃₂ left SH bits. A mask is generated having 1-bits from bit MB+32 through bit ME+32 and 0-bits elsewhere. The rotated data are inserted into register RA under control of the generated mask.

Special Registers Altered:

CR0 (if Rc=1)

Extended Mnemonics:

Example of extended mnemonics for *Rotate Left Word Immediate then Mask Insert*.

Extended: inslwi Rx,Ry,n,b
Equivalent to: rlwimi Rx,Ry,32-b,b,b+n-1

Programming Note

Let RAL represent the low-order 32 bits of register RA, with the bits numbered from 0 through 31.

rlwimi can be used to insert an n-bit field that is left-justified in the low-order 32 bits of register RS, into RAL starting at bit position b, by setting SH=32-b, MB=b, and ME=(b+n)-1. It can be used to insert an n-bit field that is right-justified in the low-order 32 bits of register RS, into RAL starting at bit position b, by setting SH=32-(b+n), MB=b, and ME=(b+n)-1.

Extended mnemonics are provided for both of these uses; see Appendix E, "Assembler Extended Mnemonics" on page 627.

3.3.13.1.1 64-bit Fixed-Point Rotate Instructions [Category: 64-Bit]

Rotate Left Doubleword Immediate then Clear Left
MD-form

rldicl RA,RS,SH,MB (Rc=0)
rldicl. RA,RS,SH,MB (Rc=1)

30	RS	RA	sh	mb	0	sh	Rc
0	6	11	16	21	27	30	31

$n \leftarrow sh_5 \parallel sh_{0:4}$
 $r \leftarrow ROTL_{64}((RS), n)$
 $b \leftarrow mb_5 \parallel mb_{0:4}$
 $m \leftarrow MASK(b, 63)$
 $RA \leftarrow r \& m$

The contents of register RS are rotated₆₄ left SH bits. A mask is generated having 1-bits from bit MB through bit 63 and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register RA.

Special Registers Altered:

CR0 (if Rc=1)

Extended Mnemonics:

Examples of extended mnemonics for *Rotate Left Doubleword Immediate then Clear Left*:

Extended:	Equivalent to:
extrdi Rx,Ry,n,b	rldicl Rx,Ry,b+n,64-n
srdi Rx,Ry,n	rldicl Rx,Ry,64-n,n
clrldi Rx,Ry,n	rldicl Rx,Ry,0,n

Programming Note

rldicl can be used to extract an n-bit field that starts at bit position b in register RS, right-justified into register RA (clearing the remaining 64-n bits of RA), by setting SH=b+n and MB=64-n. It can be used to rotate the contents of a register left (right) by n bits, by setting SH=n (64-n) and MB=0. It can be used to shift the contents of a register right by n bits, by setting SH=64-n and MB=n. It can be used to clear the high-order n bits of a register, by setting SH=0 and MB=n.

Extended mnemonics are provided for all of these uses; see Appendix E, "Assembler Extended Mnemonics" on page 627.

Rotate Left Doubleword Immediate then Clear Right
MD-form

rldicr RA,RS,SH,ME (Rc=0)
rldicr. RA,RS,SH,ME (Rc=1)

30	RS	RA	sh	me	1	sh	Rc
0	6	11	16	21	27	30	31

$n \leftarrow sh_5 \parallel sh_{0:4}$
 $r \leftarrow ROTL_{64}((RS), n)$
 $e \leftarrow me_5 \parallel me_{0:4}$
 $m \leftarrow MASK(0, e)$
 $RA \leftarrow r \& m$

The contents of register RS are rotated₆₄ left SH bits. A mask is generated having 1-bits from bit 0 through bit ME and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register RA.

Special Registers Altered:

CR0 (if Rc=1)

Extended Mnemonics:

Examples of extended mnemonics for *Rotate Left Doubleword Immediate then Clear Right*:

Extended:	Equivalent to:
extldi Rx,Ry,n,b	rldicr Rx,Ry,b,n-1
sldi Rx,Ry,n	rldicr Rx,Ry,n,63-n
clrldi Rx,Ry,n	rldicr Rx,Ry,0,63-n

Programming Note

rldicr can be used to extract an n-bit field that starts at bit position b in register RS, left-justified into register RA (clearing the remaining 64-n bits of RA), by setting SH=b and ME=n-1. It can be used to rotate the contents of a register left (right) by n bits, by setting SH=n (64-n) and ME=63. It can be used to shift the contents of a register left by n bits, by setting SH=n and ME=63-n. It can be used to clear the low-order n bits of a register, by setting SH=0 and ME=63-n.

Extended mnemonics are provided for all of these uses (some devolve to **rldicl**); see Appendix E, "Assembler Extended Mnemonics" on page 627.

Rotate Left Doubleword Immediate then Clear
MD-form

rldic RA,RS,SH,MB (Rc=0)
rldic. RA,RS,SH,MB (Rc=1)

30	RS	RA	sh	mb	2	sh	Rc
0	6	11	16	21	27	30	31

$n \leftarrow sh_5 \parallel sh_{0:4}$
 $r \leftarrow ROTL_{64}((RS), n)$
 $b \leftarrow mb_5 \parallel mb_{0:4}$
 $m \leftarrow MASK(b, \neg n)$
 $RA \leftarrow r \& m$

The contents of register RS are rotated₆₄ left SH bits. A mask is generated having 1-bits from bit MB through bit 63-SH and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register RA.

Special Registers Altered:

CR0 (if Rc=1)

Extended Mnemonics:

Example of extended mnemonics for *Rotate Left Doubleword Immediate then Clear*:

Extended: **Equivalent to:**
 clrlsldi Rx,Ry,b,n rldic Rx,Ry,n,b-n

Programming Note

rldic can be used to clear the high-order b bits of the contents of a register and then shift the result left by n bits, by setting SH=n and MB=b-n. It can be used to clear the high-order n bits of a register, by setting SH=0 and MB=n.

Extended mnemonics are provided for both of these uses (the second devolves to **rldic**); see Appendix E, "Assembler Extended Mnemonics" on page 627.

Rotate Left Doubleword then Clear Left
MDS-form

rldcl RA,RS,RB,MB (Rc=0)
rldcl. RA,RS,RB,MB (Rc=1)

30	RS	RA	RB	mb	8	Rc
0	6	11	16	21	27	31

$n \leftarrow (RB)_{58:63}$
 $r \leftarrow ROTL_{64}((RS), n)$
 $b \leftarrow mb_5 \parallel mb_{0:4}$
 $m \leftarrow MASK(b, 63)$
 $RA \leftarrow r \& m$

The contents of register RS are rotated₆₄ left the number of bits specified by (RB)_{58:63}. A mask is generated having 1-bits from bit MB through bit 63 and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register RA.

Special Registers Altered:

CR0 (if Rc=1)

Extended Mnemonics:

Example of extended mnemonics for *Rotate Left Doubleword then Clear Left*:

Extended: **Equivalent to:**
 rotld Rx,Ry,Rz rldcl Rx,Ry,Rz,0

Programming Note

rldcl can be used to extract an n-bit field that starts at variable bit position b in register RS, right-justified into register RA (clearing the remaining 64-n bits of RA), by setting RB_{58:63}=b+n and MB=64-n. It can be used to rotate the contents of a register left (right) by variable n bits, by setting RB_{58:63}=n (64-n) and MB=0.

Extended mnemonics are provided for some of these uses; see Appendix E, "Assembler Extended Mnemonics" on page 627.

**Rotate Left Doubleword then Clear Right
MDS-form**

rldcr RA,RS,RB,ME (Rc=0)
rldcr. RA,RS,RB,ME (Rc=1)

30	RS	RA	RB	me	9	Rc
0	6	11	16	21	27	31

$n \leftarrow (RB)_{58:63}$
 $r \leftarrow ROTL_{64}((RS), n)$
 $e \leftarrow me_5 \parallel me_{0:4}$
 $m \leftarrow MASK(0, e)$
 $RA \leftarrow r \& m$

The contents of register RS are rotated₆₄ left the number of bits specified by (RB)_{58:63}. A mask is generated having 1-bits from bit 0 through bit ME and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register RA.

Special Registers Altered:

CR0 (if Rc=1)

Programming Note

rldcr can be used to extract an n-bit field that starts at variable bit position b in register RS, left-justified into register RA (clearing the remaining 64-n bits of RA), by setting RB_{58:63}=b and ME=n-1. It can be used to rotate the contents of a register left (right) by variable n bits, by setting RB_{58:63}=n (64-n) and ME=63.

Extended mnemonics are provided for some of these uses (some devolve to **rldcl**); see Appendix E, "Assembler Extended Mnemonics" on page 627.

**Rotate Left Doubleword Immediate then
Mask Insert
MD-form**

rldimi RA,RS,SH,MB (Rc=0)
rldimi. RA,RS,SH,MB (Rc=1)

30	RS	RA	sh	mb	3	sh	Rc
0	6	11	16	21	27	30	31

$n \leftarrow sh_5 \parallel sh_{0:4}$
 $r \leftarrow ROTL_{64}((RS), n)$
 $b \leftarrow mb_5 \parallel mb_{0:4}$
 $m \leftarrow MASK(b, \neg n)$
 $RA \leftarrow r \& m \mid (RA) \& \neg m$

The contents of register RS are rotated₆₄ left SH bits. A mask is generated having 1-bits from bit MB through bit 63-SH and 0-bits elsewhere. The rotated data are inserted into register RA under control of the generated mask.

Special Registers Altered:

CR0 (if Rc=1)

Extended Mnemonics:

Example of extended mnemonics for *Rotate Left Doubleword Immediate then Mask Insert*:

Extended: insrdi Rx,Ry,n,b
Equivalent to: rldimi Rx,Ry,64-(b+n),b

Programming Note

rldimi can be used to insert an n-bit field that is right-justified in register RS, into register RA starting at bit position b, by setting SH=64-(b+n) and MB=b.

An extended mnemonic is provided for this use; see Appendix E, "Assembler Extended Mnemonics" on page 627.

3.3.13.2 Fixed-Point Shift Instructions

The instructions in this section perform left and right shifts.

Extended mnemonics for shifts

Immediate-form logical (unsigned) shift operations are obtained by specifying appropriate masks and shift values for certain *Rotate* instructions. A set of extended mnemonics is provided to make coding of such shifts simpler and easier to understand. Some of these are shown as examples with the *Rotate* instructions. See Appendix E, “Assembler Extended Mnemonics” on page 627 for additional extended mnemonics.

Programming Note

Any Shift Right Algebraic instruction, followed by *addze*, can be used to divide quickly by 2^n . The setting of the CA bit by the Shift Right Algebraic instructions is independent of mode.

Programming Note

Multiple-precision shifts can be programmed as shown in Section F.1, “Multiple-Precision Shifts” on page 641.

Shift Left Word

slw RA,RS,RB (Rc=0)
slw. RA,RS,RB (Rc=1)

	31	RS	RA	RB	24	Rc
0	6	11	16	21	31	

```
n ← (RB)59:63
r ← ROTL32((RS)32:63, n)
if (RB)58 = 0 then
    m ← MASK(32, 63-n)
else m ← 640
RA ← r & m
```

The contents of the low-order 32 bits of register RS are shifted left the number of bits specified by (RB)_{58:63}. Bits shifted out of position 32 are lost. Zeros are supplied to the vacated positions on the right. The 32-bit result is placed into RA_{32:63}. RA_{0:31} are set to zero. Shift amounts from 32 to 63 give a zero result.

Special Registers Altered:

CR0 (if Rc=1)

Shift Right Word

srw RA,RS,RB (Rc=0)
srw. RA,RS,RB (Rc=1)

	31	RS	RA	RB	536	Rc
0	6	11	16	21	31	

```
n ← (RB)59:63
r ← ROTL32((RS)32:63, 64-n)
if (RB)58 = 0 then
    m ← MASK(n+32, 63)
else m ← 640
RA ← r & m
```

The contents of the low-order 32 bits of register RS are shifted right the number of bits specified by (RB)_{58:63}. Bits shifted out of position 63 are lost. Zeros are supplied to the vacated positions on the left. The 32-bit result is placed into RA_{32:63}. RA_{0:31} are set to zero. Shift amounts from 32 to 63 give a zero result.

Special Registers Altered:

CR0 (if Rc=1)

Shift Right Algebraic Word Immediate
X-form

srawi RA,RS,SH (Rc=0)
srawi. RA,RS,SH (Rc=1)

31	RS	RA	SH	824	Rc
0	6	11	16	21	31

$n \leftarrow SH$
 $r \leftarrow ROTL_{32}((RS)_{32:63}, 64-n)$
 $m \leftarrow MASK(n+32, 63)$
 $s \leftarrow (RS)_{32}$
 $RA \leftarrow r \& m \mid ({}^{64}s) \& \neg m$
 $CA \leftarrow s \& ((r \& \neg m)_{32:63} \neq 0)$

The contents of the low-order 32 bits of register RS are shifted right SH bits. Bits shifted out of position 63 are lost. Bit 32 of RS is replicated to fill the vacated positions on the left. The 32-bit result is placed into RA_{32:63}. Bit 32 of RS is replicated to fill RA_{0:31}. CA is set to 1 if the low-order 32 bits of (RS) contain a negative number and any 1-bits are shifted out of position 63; otherwise CA is set to 0. A shift amount of zero causes RA to receive EXTS((RS)_{32:63}), and CA to be set to 0.

Special Registers Altered:

CA
CR0 (if Rc=1)

Shift Right Algebraic Word **X-form**

sraw RA,RS,RB (Rc=0)
sraw. RA,RS,RB (Rc=1)

 $m \leftarrow MASK(n, 63)$
 else $m \leftarrow {}^{64}0$
 $s \leftarrow (RS)_0$
 $RA \leftarrow r \& m \mid ({}^{64}s) \& \neg m$
 $CA \leftarrow s \& ((r \& \neg m) \neq 0)$

The contents of register RS are shifted right the number of bits specified by $(RB)_{57:63}$. Bits shifted out of position 63 are lost. Bit 0 of RS is replicated to fill the vacated positions on the left. The result is placed into register RA. CA is set to 1 if (RS) is negative and any 1-bits are shifted out of position 63; otherwise CA is set to 0. A shift amount of zero causes RA to be set equal to (RS), and CA to be set to 0. Shift amounts from 64 to 127 give a result of 64 sign bits in RA, and cause CA to receive the sign bit of (RS).

Special Registers Altered:

CA
 CR0 (if Rc=1)

3.3.14 Binary Coded Decimal (BCD) Assist Instructions [Category: Embedded.Phased-in, Server]

The *Binary Coded Decimal Assist* instructions operate on Binary Coded Decimal operands (*cbcdtd* and

addg6s) and Decimal Floating-Point operands (*cdt-bcd*) See Chapter 5. for additional information.

Convert Declets To Binary Coded Decimal X-form

cdtbcd RA, RS

```
do i = 0 to 1
  n ← i x 32
  RAn+0:n+7 ← 0
  RAn+8:n+19 ← DEC_TO_BCD( (RS)n+12:n+21 )
  RAn+20:n+31 ← DEC_TO_BCD( (RS)n+22:n+31 )
```

The low-order 20 bits of each word of register RS contain two declets which are converted to six, 4-bit BCD fields; each set of six, 4-bit BCD fields is placed into the low-order 24 bits of the corresponding word in RA. The high-order 8 bits in each word of RA are set to 0.

Special Registers Altered:

None

Convert Binary Coded Decimal To Declets X-form

cbcdtd RA, RS

```
do i = 0 to 1
  n ← i x 32
  RAn+0:n+11 ← 0
  RAn+12:n+21 ← BCD_TO_DEC( (RS)n+8:n+19 )
  RAn+22:n+31 ← BCD_TO_DEC( (RS)n+20:n+31 )
```

The low-order 24 bits of each word of register RS contain six, 4-bit BCD fields which are converted to two declets; each set of two declets is placed into the low-order 20 bits of the corresponding word in RA. The high-order 12 bits in each word of RA are set to 0.

If a 4-bit BCD field has a value greater than 9 the results are undefined.

Special Registers Altered:

None

Add and Generate Sixes XO-Form

addg6s RT,RA,RB

```
do i = 0 to 15
  dci ← carry_out(RA4xi:63 + RB4xi:63)
  c ← 4(dc0) || 4(dc1) || ... || 4(dc15)
  RT ← (¬c) & 0x6666_6666_6666_6666
```

The contents of register RA are added to the contents of register RB. Sixteen carry bits are produced, one for each carry out of decimal position *n* (bit position *4xn*).

A doubleword is composed from the 16 carry bits, and placed into RT. The doubleword consists of a decimal six (0b0110) in every decimal digit position for which the corresponding carry bit is 0, and a zero (0b0000) in every position for which the corresponding carry bit is 1.

Special Registers Altered:

None

Programming Note

addg6s can be used to add or subtract two BCD operands. In these examples it is assumed that r0 contains 0x666...666. (BCD data formats are described in Section 5.3.)

Addition of the unsigned BCD operand in register RA to the unsigned BCD operand in register RB can be accomplished as follows.

```
add    r1,RA,r0
add    r2,r1,RB
addg6s RT,r1,RB
subf   RT,RT,r2# RT = RA +BCD RB
```

Subtraction of the unsigned BCD operand in register RA from the unsigned BCD operand in register RB can be accomplished as follows. (In this example it is assumed that RB is not register 0.)

```
addi   r1,RB,1
nor    r2,RA,RA# one's complement of RA
add    r3,r1,r2
addg6s RT,r1,r2
subf   RT,RT,r3# RT = RB -BCD RA
```

Additional instructions are needed to handle signed BCD operands, and BCD operands that occupy more than one register (e.g., unsigned BCD operands that have more than 16 decimal digits).

3.3.15 Move To/From System Register Instructions

The *Move To Condition Register Fields* instruction has a preferred form; see Section 1.8.1, “Preferred Instruction Forms” on page 23. In the preferred form, the FXM field satisfies the following rule.

- Exactly one bit of the FXM field is set to 1.

Extended mnemonics

Extended mnemonics are provided for the *mtspr* and *mfspr* instructions so that they can be coded with the

SPR name as part of the mnemonic rather than as a numeric operand. An extended mnemonic is provided for the *mtcrf* instruction for compatibility with old software (written for a version of the architecture that precedes Version 2.00) that uses it to set the entire Condition Register. Some of these extended mnemonics are shown as examples with the relevant instructions. See Appendix E, “Assembler Extended Mnemonics” on page 627 for additional extended mnemonics.

Move To Special Purpose Register

XFX-form

mtspr SPR,RS

0	31	RS	spr	467	/
	6		11	21	31

```
n ← spr5:9 || spr0:4
if n = 13 then see Book III-S
else
  if length(SPR(n)) = 64 then
    SPR(n) ← (RS)
  else
    SPR(n) ← (RS)32:63
```

The SPR field denotes a Special Purpose Register, encoded as shown in the table below. Unless the SPR field contains 13 (denoting the AMR<S>), the contents of register RS are placed into the designated Special Purpose Register. For Special Purpose Registers that are 32 bits long, the low-order 32 bits of RS are placed into the SPR.

The AMR (Authority Mask Register) is used for “storage protection” in the Server environment. This use, and operation of *mtspr* for the AMR, are described in Book III-S.

decimal	SPR ¹		Register Name
	spr _{5:9}	spr _{0:4}	
1	00000	00001	XER
8	00000	01000	LR
9	00000	01001	CTR
13	00000	01101	AMR ⁵
256	01000	00000	VRSAVE
512	10000	00000	SPEFSCR ²
896	11100	00000	PPR ³
898	11100	00010	PPR32 ⁴

¹ Note that the order of the two 5-bit halves of the SPR number is reversed.

² Category: SPE.

³ Category: Server; see Book III-S.

⁴ Category: Phased-In. See Section 3.1 of Book II.

If execution of this instruction is attempted specifying an SPR number that is not shown above, or an SPR number that is shown above but is in a category that is not supported by the implementation, one of the following occurs.

- If spr₀ = 0, the illegal instruction error handler is invoked.
- If spr₀ = 1, the system privileged instruction error handler is invoked.

A complete description of this instruction can be found in Book III.

Special Registers Altered:

See above

Extended Mnemonics:

Examples of extended mnemonics for *Move To Special Purpose Register*:

Extended:	Equivalent to:
mtxr Rx	mtspr 1,Rx
mtlr Rx	mtspr 8,Rx
mtctr Rx	mtspr 9,Rx
mtppr Rx	mtspr 896,Rx
mtppr32 Rx	mtspr 898,Rx

Programming Note

The AMR is part of the “context” of the program (see Book III-S). Therefore modification of the AMR requires “synchronization” by software. For this reason, most operating systems provide a system library program that application programs can use to modify the AMR.

Compiler and Assembler Note

For the *mtspr* and *mfspr* instructions, the SPR number coded in Assembler language does not appear directly as a 10-bit binary number in the instruction. The number coded is split into two 5-bit halves that are reversed in the instruction, with the high-order 5 bits appearing in bits 16:20 of the instruction and the low-order 5 bits in bits 11:15.

Move From Special Purpose Register XFX-form

mf spr RT, SPR

31	RT	spr	339	/
0	6	11	21	31

```
n ← spr5:9 || spr0:4
if length(SPR(n)) = 64 then
  RT ← SPR(n)
else
  RT ← 320 || SPR(n)
```

The SPR field denotes a Special Purpose Register, encoded as shown in the table below. The contents of the designated Special Purpose Register are placed into register RT. For Special Purpose Registers that are 32 bits long, the low-order 32 bits of RT receive the contents of the Special Purpose Register and the high-order 32 bits of RT are set to zero.

decimal	SPR ¹		Register Name
	spr _{5:9}	spr _{0:4}	
1	00000	00001	XER
8	00000	01000	LR

¹ Note that the order of the two 5-bit halves of the SPR number is reversed.

² Category: Embedded.

³ See Chapter 5 of Book II.

⁴ Category: SPE.

⁵ Category: Alternate Time Base.

⁶ Category: Server; see Book III-S.

⁷ Category: Phased-In. See Section 3.1 of Book II.

A complete description of this instruction can be found in Book III.

Special Registers Altered:

None

Extended Mnemonics:

Examples of extended mnemonics for Move From Special Purpose Register:

Extended:

mfxer Rx
mflr Rx
mfctr Rx

Equivalent to:

mf spr Rx, 1
mf spr Rx, 8
mf spr Rx, 9

Note

See the Notes that appear with *mtspr*.

If execution of this instruction is attempted specifying an SPR number that is not shown above, or an SPR number that is shown above but is in a category that is not supported by the implementation, one of the following occurs.

- If spr₀ = 0, the illegal instruction error handler is invoked.
- If spr₀ = 1, the system privileged instruction error handler is invoked.

Move To Condition Register Fields XFX-form

mtrcf FXM,RS

31	RS	0	FXM	/	144	/
0	6	11	12	20	21	31

$$\text{mask} \leftarrow {}^4(\text{FXM}_0) \mid \mid {}^4(\text{FXM}_1) \mid \mid \dots \mid {}^4(\text{FXM}_7)$$

$$\text{CR} \leftarrow ((\text{RS})_{32:63} \& \text{mask}) \mid (\text{CR} \& \neg \text{mask})$$

The contents of bits 32:63 of register RS are placed into the Condition Register under control of the field mask specified by FXM. The field mask identifies the 4-bit fields affected. Let i be an integer in the range 0-7. If $\text{FXM}_i=1$ then CR field i (CR bits $4 \times i + 32 : 4 \times i + 35$) is set to the contents of the corresponding field of the low-order 32 bits of RS.

Special Registers Altered:

CR fields selected by mask

Extended Mnemonics:

Example of extended mnemonics for *Move To Condition Register Fields*:

Extended:	Equivalent to:
mtrcf Rx	mtrcf 0xFF,Rx

Programming Note

In the preferred form of this instruction (*mtrcf*), only one Condition Register field is updated.

Move From Condition Register XFX-form

mfcr RT

31	RT	0	///	19	/
0	6	11	12	21	31

$$\text{RT} \leftarrow {}^{32}0 \mid \mid \text{CR}$$

The contents of the Condition Register are placed into $\text{RT}_{32:63}$. $\text{RT}_{0:31}$ are set to 0.

Special Registers Altered:

None

3.3.15.1 Move to/From One Condition Register Field Instructions

Move To One Condition Register Field XFX-form

mtocrf FXM,RS

31	RS	1	FXM	/	144	/
0	6	11	12	20	21	31

```

count ← 0
do i = 0 to 7
  if FXMi = 1 then
    n ← i
    count ← count + 1
if count = 1 then
  CR4×n+32:4×n+35 ← (RS)4×n+32:4×n+35
else CR ← undefined

```

If exactly one bit of the FXM field is set to 1, let n be the position of that bit in the field ($0 \leq n \leq 7$). The contents of bits $4 \times n + 32 : 4 \times n + 35$ of register RS are placed into CR field n (CR bits $4 \times n + 32 : 4 \times n + 35$). Otherwise, the contents of the Condition Register are undefined.

Special Registers Altered:

CR field selected by FXM

Programming Note

These forms of the *mtocrf* and *mfcf* instructions are intended to replace the old forms of the instructions (the forms shown in page 102), which will eventually be phased out of the architecture. The new forms are backward compatible with most processors that comply with versions of the architecture that precede Version 2.00. On those processors, the new forms are treated as the old forms.

However, on some processors that comply with versions of the architecture that precede Version 2.00 the new forms may be treated as follows:

mtocrf: may cause the system illegal instruction error handler to be invoked

mfcf: may place an undefined value into register RT

Move From One Condition Register Field XFX-form

mfcfcrf RT,FXM

31	RT	1	FXM	/	19	/
0	6	11	12	20	21	31

```

RT ← undefined
count ← 0
do i = 0 to 7
  if FXMi = 1 then
    n ← i
    count ← count + 1
if count = 1 then
  RT4×n+32:4×n+35 ← CR4×n+32:4×n+35

```

If exactly one bit of the FXM field is set to 1, let n be the position of that bit in the field ($0 \leq n \leq 7$). The contents of CR field n (CR bits $4 \times n + 32 : 4 \times n + 35$) are placed into bits $4 \times n + 32 : 4 \times n + 35$ of register RT and the contents of the remaining bits of register RT are undefined. Otherwise, the contents of register RT are undefined.

4.1 Floating-Point Facility Overview

This chapter describes the registers and instructions that make up the Floating-Point Facility.

The processor (augmented by appropriate software support, where required) implements a floating-point

system compliant with the ANSI/IEEE Standard 754-1985, "IEEE Standard for Binary Floating-Point Arithmetic" (hereafter referred to as "the IEEE standard"). That standard defines certain required "operations" (addition, subtraction, etc.). Herein, the term "floating-point operation" is used to refer to one of these required operations and to additional operations defined (e.g., those performed by *Multiply-Add* or *Reciprocal Estimate* instructions). A Non-IEEE mode is

also provided. This mode, which may produce results not in strict compliance with the IEEE standard, allows shorter latency.

Instructions are provided to perform arithmetic, rounding, conversion, comparison, and other operations in floating-point registers; to move floating-point data between storage and these registers; and to manipulate the Floating-Point Status and Control Register explicitly.

These instructions are divided into two categories.

- computational instructions

The computational instructions are those that perform addition, subtraction, multiplication, division, extracting the square root, rounding, conversion, comparison, and combinations of these operations. These instructions provide the floating-point operations. They place status information into the Floating-Point Status and Control Register. They are the instructions described in Sections 4.6.6 through 4.6.8.

- non-computational instructions

The non-computational instructions are those that perform loads and stores, move the contents of a floating-point register to another floating-point register possibly altering the sign, manipulate the Floating-Point Status and Control Register explicitly, and select the value from one of two floating-point registers based on the value in a third floating-point register. The operations performed by these instructions are not considered floating-point operations. With the exception of the instructions that manipulate the Floating-Point Status and Control Register explicitly, they do not alter the Floating-Point Status and Control Register. They are the instructions described in Sections 4.6.2 through 4.6.5, and 4.6.10.

A floating-point number consists of a signed exponent and a signed significand. The quantity expressed by this number is the product of the significand and the number 2^{exponent} . Encodings are provided in the data format to represent finite numeric values, \pm Infinity, and values that are “Not a Number” (NaN). Operations involving infinities produce results obeying traditional mathematical conventions. NaNs have no mathematical interpretation. Their encoding permits a variable diagnostic information field. They may be used to indicate such things as uninitialized variables and can be produced by certain invalid operations.

There is one class of exceptional events that occur during instruction execution that is unique to the Floating-Point Facility: the Floating-Point Exception. Floating-point exceptions are signaled with bits set in the Floating-Point Status and Control Register (FPSCR). They can cause the system floating-point enabled exception error handler to be invoked, precisely or imprecisely, if the proper control bits are set.

Floating-Point Exceptions

The following floating-point exceptions are detected by the processor:

- Invalid Operation Exception (VX)
 - SNaN (VXSNAN)
 - Infinity–Infinity (VXISI)
 - Infinity÷Infinity (VXIDI)
 - Zero÷Zero (VXZDZ)
 - Infinity×Zero (VXIMZ)
 - Invalid Compare (VXVC)
 - Software-Defined Condition (VXSOF)
 - Invalid Square Root (VXSQRT)
 - Invalid Integer Convert (VXCVI)
- Zero Divide Exception (ZX)
- Overflow Exception (OX)
- Underflow Exception (UX)
- Inexact Exception (XX)

Each floating-point exception, and each category of Invalid Operation Exception, has an exception bit in the FPSCR. In addition, each floating-point exception has a corresponding enable bit in the FPSCR. See Section 4.2.2, “Floating-Point Status and Control Register” on page 107 for a description of these exception and enable bits, and Section 4.4, “Floating-Point Exceptions” on page 114 for a detailed discussion of floating-point exceptions, including the effects of the enable bits.

4.2 Floating-Point Facility Registers

4.2.1 Floating-Point Registers

Implementations of this architecture provide 32 floating-point registers (FPRs). The floating-point instruction formats provide 5-bit fields for specifying the FPRs to be used in the execution of the instruction. The FPRs are numbered 0-31. See Figure 48 on page 107.

Each FPR contains 64 bits that support the floating-point double format. Every instruction that interprets the contents of an FPR as a floating-point value uses the floating-point double format for this interpretation.

The computational instructions, and the *Move* and *Select* instructions, operate on data located in FPRs and, with the exception of the *Compare* instructions, place the result value into an FPR and optionally (when Rc=1) place status information into the Condition Register. Instruction forms with Rc=1 are part of Category: Floating-Point.Record.

Load Double and *Store Double* instructions are provided that transfer 64 bits of data between storage and the FPRs with no conversion. *Load Single* instructions are provided to transfer and convert floating-point val-

ues in floating-point single format from storage to the same value in floating-point double format in the FPRs. *Store Single* instructions are provided to transfer and convert floating-point values in floating-point double format from the FPRs to the same value in floating-point single format in storage.

Instructions are provided that manipulate the Floating-Point Status and Control Register and the Condition Register explicitly. Some of these instructions copy data from an FPR to the Floating-Point Status and Control Register or vice versa.

The computational instructions and the *Select* instruction accept values from the FPRs in double format. For single-precision arithmetic instructions, all input values must be representable in single format; if they are not, the result placed into the target FPR, and the setting of status bits in the FPSCR and in the Condition Register (if Rc=1), are undefined.

Figure 48. Floating-Point Registers

4.2.2 Floating-Point Status and Control Register

The Floating-Point Status and Control Register (FPSCR) controls the handling of floating-point exceptions and records status resulting from the floating-point operations. Bits 32:55 are status bits. Bits 56:63 are control bits.

The exception bits in the FPSCR (bits 35:44, 53:55) are sticky; that is, once set to 1 they remain set to 1 until they are set to 0 by an *mcrfs*, *mtfsfi*, *mtfsf*, or *mtfsb0* instruction. The exception summary bits in the FPSCR (FX, FEX, and VX, which are bits 32:34) are not considered to be “exception bits”, and only FX is sticky.

FEX and VX are simply the ORs of other FPSCR bits. Therefore these two bits are not listed among the FPSCR bits affected by the various instructions.

Figure 49. Floating-Point Status and Control Register

The bit definitions for the FPSCR are as follows.

Bit(s)	Description
0:31	Reserved
32	Floating-Point Exception Summary (FX) Every floating-point instruction, except <i>mtfsfi</i> and <i>mtfsf</i> , implicitly sets FPSCR _{FX} to 1 if that instruction causes any of the floating-point exception bits in the FPSCR to change from 0 to 1. <i>mcrfs</i> , <i>mtfsfi</i> , <i>mtfsf</i> , <i>mtfsb0</i> , and <i>mtfsb1</i> can alter FPSCR _{FX} explicitly.

Programming Note

FPSCR_{FX} is defined not to be altered implicitly by *mtfsfi* and *mtfsf* because permitting these instructions to alter FPSCR_{FX} implicitly could cause a paradox. An example is an *mtfsfi* or *mtfsf* instruction that supplies 0 for FPSCR_{FX} and 1 for FPSCR_{OX}, and is executed when FPSCR_{OX}=0. See also the Programming Notes with the definition of these two instructions.

33	Floating-Point Enabled Exception Summary (FEX) This bit is the OR of all the floating-point exception bits masked by their respective enable bits. <i>mcrfs</i> , <i>mtfsfi</i> , <i>mtfsf</i> , <i>mtfsb0</i> , and <i>mtfsb1</i> cannot alter FPSCR _{FEX} explicitly.
34	Floating-Point Invalid Operation Exception Summary (VX) This bit is the OR of all the Invalid Operation exception bits. <i>mcrfs</i> , <i>mtfsfi</i> , <i>mtfsf</i> , <i>mtfsb0</i> , and <i>mtfsb1</i> cannot alter FPSCR _{VX} explicitly.
35	Floating-Point Overflow Exception (OX) See Section 4.4.3, “Overflow Exception” on page 117.
36	Floating-Point Underflow Exception (UX) See Section 4.4.4, “Underflow Exception” on page 118.
37	Floating-Point Zero Divide Exception (ZX) See Section 4.4.2, “Zero Divide Exception” on page 117.
38	Floating-Point Inexact Exception (XX) See Section 4.4.5, “Inexact Exception” on page 119. FPSCR _{XX} is a sticky version of FPSCR _{F1} (see below). Thus the following rules completely describe how FPSCR _{XX} is set by a given instruction. <ul style="list-style-type: none"> ■ If the instruction affects FPSCR_{F1}, the new value of FPSCR_{XX} is obtained by ORing the old value of FPSCR_{XX} with the new value of FPSCR_{F1}.

- If the instruction does not affect $FPSCR_{FI}$, the value of $FPSCR_{XX}$ is unchanged.
 - 39 **Floating-Point Invalid Operation Exception (SNaN)** (VXSNaN)
See Section 4.4.1, “Invalid Operation Exception” on page 116.
 - 40 **Floating-Point Invalid Operation Exception ($\infty - \infty$)** (VXISI)
See Section 4.4.1.
 - 41 **Floating-Point Invalid Operation Exception ($\infty \div \infty$)** (VXIDI)
See Section 4.4.1.
 - 42 **Floating-Point Invalid Operation Exception ($0 \div 0$)** (VXZDZ)
See Section 4.4.1.
 - 43 **Floating-Point Invalid Operation Exception ($\infty \times 0$)** (VXIMZ)
See Section 4.4.1.
 - 44 **Floating-Point Invalid Operation Exception (Invalid Compare)** (VXVC)
See Section 4.4.1.
 - 45 **Floating-Point Fraction Rounded** (FR)
The last *Arithmetic* or *Rounding and Conversion* instruction incremented the fraction during rounding. See Section 4.3.6, “Rounding” on page 113. This bit is not sticky.
 - 46 **Floating-Point Fraction Inexact** (FI)
The last *Arithmetic* or *Rounding and Conversion* instruction either produced an inexact result during rounding or caused a disabled Overflow Exception. See Section 4.3.6. This bit is not sticky.

See the definition of $FPSCR_{XX}$, above, regarding the relationship between $FPSCR_{FI}$ and $FPSCR_{XX}$.
 - 47:51 **Floating-Point Result Flags** (FPRF)
Arithmetic, rounding, and *Convert From Integer* instructions set this field based on the result placed into the target register and on the target precision, except that if any portion of the result is undefined then the value placed into FPRF is undefined. Floating-point *Compare* instructions set this field based on the relative values of the operands being compared. For *Convert To Integer* instructions, the value placed into FPRF is undefined. Additional details are given below.
- Programming Note**

A single-precision operation that produces a denormalized result sets FPRF to indicate a denormalized number. When possible, single-precision denormalized numbers are represented in normalized double format in the target register.
- 47 **Floating-Point Result Class Descriptor** (C)
Arithmetic, rounding, and *Convert From Integer* instructions may set this bit with the FPCC bits, to indicate the class of the result as shown in Figure 50 on page 109.
 - 48:51 **Floating-Point Condition Code** (FPCC)
Floating-point *Compare* instructions set one of the FPCC bits to 1 and the other three FPCC bits to 0. Arithmetic, rounding, and *Convert From Integer* instructions may set the FPCC bits with the C bit, to indicate the class of the result as shown in Figure 50 on page 109. Note that in this case the high-order three bits of the FPCC retain their relational significance indicating that the value is less than, greater than, or equal to zero.
 - 48 **Floating-Point Less Than or Negative** (FL or <)
 - 49 **Floating-Point Greater Than or Positive** (FG or >)
 - 50 **Floating-Point Equal or Zero** (FE or =)
 - 51 **Floating-Point Unordered or NaN** (FU or ?)
 - 52 Reserved
 - 53 **Floating-Point Invalid Operation Exception (Software-Defined Condition)** (VXSOF)
This bit can be altered only by *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, or *mtfsb1*. See Section 4.4.1.
- Programming Note**

$FPSCR_{VXSOF}$ can be used by software to indicate the occurrence of an arbitrary, software-defined, condition that is to be treated as an Invalid Operation Exception. For example, the bit could be set by a program that computes a base 10 logarithm if the supplied input is negative.
- 54 **Floating-Point Invalid Operation Exception (Invalid Square Root)** (VXSQRT)
See Section 4.4.1.
 - 55 **Floating-Point Invalid Operation Exception (Invalid Integer Convert)** (VXCVI)
See Section 4.4.1.

- 56 **Floating-Point Invalid Operation Exception Enable (VE)**
See Section 4.4.1.
- 57 **Floating-Point Overflow Exception Enable (OE)**
See Section 4.4.3, “Overflow Exception” on page 117.
- 58 **Floating-Point Underflow Exception Enable (UE)**
See Section 4.4.4, “Underflow Exception” on page 118.
- 59 **Floating-Point Zero Divide Exception Enable (ZE)**
See Section 4.4.2, “Zero Divide Exception” on page 117.
- 60 **Floating-Point Inexact Exception Enable (XE)**
See Section 4.4.5, “Inexact Exception” on page 119.
- 61 **Floating-Point Non-IEEE Mode (NI)**
Floating-point non-IEEE mode is optional. If floating-point non-IEEE mode is not implemented, this bit is treated as reserved, and the remainder of the definition of this bit does not apply.

If floating-point non-IEEE mode is implemented, this bit has the following meaning.

- 0 The processor is not in floating-point non-IEEE mode (i.e., all floating-point operations conform to the IEEE standard).
- 1 The processor is in floating-point non-IEEE mode.

When the processor is in floating-point non-IEEE mode, the remaining FPSCR bits may have meanings different from those given in this document, and floating-point operations need not conform to the IEEE standard. The effects of executing a given floating-point instruction with $FPSCR_{NI}=1$, and any additional requirements for using non-IEEE mode, are implementation-dependent. The results of executing a given instruction in non-IEEE mode may vary between implementations, and between different executions on the same implementation.

Programming Note

When the processor is in floating-point non-IEEE mode, the results of floating-point operations may be approximate, and performance for these operations may be better, more predictable, or less data-dependent than when the processor is not in non-IEEE mode. For example, in non-IEEE mode an implementation may return 0 instead of a denormalized number, and may return a large number instead of an infinity.

- 62:63 **Floating-Point Rounding Control (RN)** See Section 4.3.6, “Rounding” on page 113.

- 00 Round to Nearest
01 Round toward Zero
10 Round toward +Infinity
11 Round toward -Infinity

Result Flags	Result Value Class
C < > = ?	
1 0 0 0 1	Quiet NaN
0 1 0 0 1	- Infinity
0 1 0 0 0	- Normalized Number
1 1 0 0 0	- Denormalized Number
1 0 0 1 0	- Zero

Figure 50. Floating-Point Result Flags

4.3 Floating-Point Data

4.3.1 Data Format

This architecture defines the representation of a floating-point value in two different binary fixed-length formats. The format may be a 32-bit single format for a single-precision value or a 64-bit double format for a double-precision value. The single format may be used for data in storage. The double format may be used for data in storage and for data in floating-point registers.

The lengths of the exponent and the fraction fields differ between these two formats. The structure of the single and double formats is shown below.

Figure 51. Floating-point single format

Figure 52. Floating-point double format

Values in floating-point format are composed of three fields:

S sign bit
 EXP exponent+bias
 FRACTION fraction

Representation of numeric values in the floating-point formats consists of a sign bit (S), a biased exponent (EXP), and the fraction portion (FRACTION) of the significand. The significand consists of a leading implied bit concatenated on the right with the FRACTION. This leading implied bit is 1 for normalized numbers and 0 for denormalized numbers and is located in the unit bit position (i.e., the first bit to the left of the binary point). Values representable within the two floating-point formats can be specified by the parameters listed in Figure 53.

	Format	
	Single	Double
Exponent Bias	+127	+1023
Maximum Exponent	+127	+1023
Minimum Exponent	-126	-1022
Widths (bits)		
Format	32	64
Sign	1	1
Exponent	8	11
Fraction	23	52
Significand	24	53

Figure 53. IEEE floating-point fields

The architecture requires that the FPRs of the Floating-Point Facility support the floating-point double format only.

4.3.2 Value Representation

This architecture defines numeric and non-numeric values representable within each of the two supported formats. The numeric values are approximations to the real numbers and include the normalized numbers, denormalized numbers, and zero values. The non-numeric values representable are the infinities and the Not a Numbers (NaNs). The infinities are adjoined to the real numbers, but are not numbers themselves, and the standard rules of arithmetic do not hold when they are used in an operation. They are related to the real numbers by order alone. It is possible however to define restricted operations among numbers and infi-

ties as defined below. The relative location on the real number line for each of the defined entities is shown in Figure 54.

Figure 54. Approximation to real numbers

The NaNs are not related to the numeric values or infinities by order or value but are encodings used to convey diagnostic information such as the representation of uninitialized variables.

The following is a description of the different floating-point values defined in the architecture:

Binary floating-point numbers

Machine representable values used as approximations to real numbers. Three categories of numbers are supported: normalized numbers, denormalized numbers, and zero values.

Normalized numbers (\pm NOR)

These are values that have a biased exponent value in the range:

1 to 254 in single format
 1 to 2046 in double format

They are values in which the implied unit bit is 1. Normalized numbers are interpreted as follows:

$$\text{NOR} = (-1)^s \times 2^E \times (1.\text{fraction})$$

where s is the sign, E is the unbiased exponent, and 1.fraction is the significand, which is composed of a leading unit bit (implied bit) and a fraction part.

The ranges covered by the magnitude (M) of a normalized floating-point number are approximately equal to:

Single Format:

$$1.2 \times 10^{-38} \leq M \leq 3.4 \times 10^{38}$$

Double Format:

$$2.2 \times 10^{-308} \leq M \leq 1.8 \times 10^{308}$$

Zero values (\pm 0)

These are values that have a biased exponent value of zero and a fraction value of zero. Zeros can have a positive or negative sign. The sign of zero is ignored by comparison operations (i.e., comparison regards +0 as equal to -0).

Denormalized numbers (\pm DEN)

These are values that have a biased exponent value of zero and a nonzero fraction value. They are nonzero numbers smaller in magnitude than the representable normalized numbers. They are values in which the implied unit bit is 0. Denormalized numbers are interpreted as follows:

$$\text{DEN} = (-1)^s \times 2^{E_{\text{min}}} \times (0.\text{fraction})$$

where E_{\min} is the minimum representable exponent value (-126 for single-precision, -1022 for double-precision).

Infinities ($\pm \infty$)

These are values that have the maximum biased exponent value:

255 in single format
2047 in double format

and a zero fraction value. They are used to approximate values greater in magnitude than the maximum normalized value.

Infinity arithmetic is defined as the limiting case of real arithmetic, with restricted operations defined among numbers and infinities. Infinities and the real numbers can be related by ordering in the affine sense:

$$-\infty < \text{every finite number} < +\infty$$

Arithmetic on infinities is always exact and does not signal any exception, except when an exception occurs due to the invalid operations as described in Section 4.4.1, “Invalid Operation Exception” on page 116.

For comparison operations, $+\infty$ compares equal to $+\infty$ and $-\infty$ compares equal to $-\infty$.

Not a Numbers (NaNs)

These are values that have the maximum biased exponent value and a nonzero fraction value. The sign bit is ignored (i.e., NaNs are neither positive nor negative). If the high-order bit of the fraction field is 0 then the NaN is a *Signaling NaN*; otherwise it is a *Quiet NaN*.

Signaling NaNs are used to signal exceptions when they appear as operands of computational instructions.

Quiet NaNs are used to represent the results of certain invalid operations, such as invalid arithmetic operations on infinities or on NaNs, when Invalid Operation Exception is disabled ($FPSCR_{VE}=0$). Quiet NaNs propagate through all floating-point operations except ordered comparison, *Floating Round to Single-Precision*, and conversion to integer. Quiet NaNs do not signal exceptions, except for ordered comparison and conversion to integer operations. Specific encodings in QNaNs can thus be preserved through a sequence of floating-point operations, and used to convey diagnostic information to help identify results from invalid operations.

When a QNaN is the result of a floating-point operation because one of the operands is a NaN or because a QNaN was generated due to a disabled Invalid Operation Exception, then the following rule is applied to determine the NaN with the high-order fraction bit set to 1 that is to be stored as the result.

```
if (FRA) is a NaN
    then FRT ← (FRA)
    else if (FRB) is a NaN
        then if instruction is frsp
```

```
    then FRT ← (FRB)0:34 || 290
    else FRT ← (FRB)
    else if (FRC) is a NaN
        then FRT ← (FRC)
        else if generated QNaN
            then FRT ← generated QNaN
```

If the operand specified by FRA is a NaN, then that NaN is stored as the result. Otherwise, if the operand specified by FRB is a NaN (if the instruction specifies an FRB operand), then that NaN is stored as the result, with the low-order 29 bits of the result set to 0 if the instruction is *frsp*. Otherwise, if the operand specified by FRC is a NaN (if the instruction specifies an FRC operand), then that NaN is stored as the result. Otherwise, if a QNaN was generated due to a disabled Invalid Operation Exception, then that QNaN is stored as the result. If a QNaN is to be generated as a result, then the QNaN generated has a sign bit of 0, an exponent field of all 1s, and a high-order fraction bit of 1 with all other fraction bits 0. Any instruction that generates a QNaN as the result of a disabled Invalid Operation Exception generates this QNaN (i.e., $0x7FF8_0000_0000_0000$).

A double-precision NaN is considered to be representable in single format if and only if the low-order 29 bits of the double-precision NaN's fraction are zero.

4.3.3 Sign of Result

The following rules govern the sign of the result of an arithmetic, rounding, or conversion operation, when the operation does not yield an exception. They apply even when the operands or results are zeros or infinities.

- The sign of the result of an add operation is the sign of the operand having the larger absolute value. If both operands have the same sign, the sign of the result of an add operation is the same as the sign of the operands. The sign of the result of the subtract operation $x-y$ is the same as the sign of the result of the add operation $x+(-y)$.

When the sum of two operands with opposite sign, or the difference of two operands with the same sign, is exactly zero, the sign of the result is positive in all rounding modes except Round toward $-\infty$, in which mode the sign is negative.

- The sign of the result of a multiply or divide operation is the Exclusive OR of the signs of the operands.
- The sign of the result of a *Square Root* or *Reciprocal Square Root Estimate* operation is always positive, except that the square root of -0 is -0 and the reciprocal square root of -0 is $-\infty$.
- The sign of the result of a *Round to Single-Precision*, or *Convert From Integer*, or *Round to Integer* operation is the sign of the operand being converted.

For the *Multiply-Add* instructions, the rules given above are applied first to the multiply operation and then to the add or subtract operation (one of the inputs to the add or subtract operation is the result of the multiply operation).

4.3.4 Normalization and Denormalization

The intermediate result of an arithmetic or *frsp* instruction may require normalization and/or denormalization as described below. Normalization and denormalization do not affect the sign of the result.

When an arithmetic or rounding instruction produces an intermediate result which carries out of the significand, or in which the significand is nonzero but has a leading zero bit, it is not a normalized number and must be normalized before it is stored. For the carry-out case, the significand is shifted right one bit, with a one shifted into the leading significand bit, and the exponent is incremented by one. For the leading-zero case, the significand is shifted left while decrementing its exponent by one for each bit shifted, until the leading significand bit becomes one. The Guard bit and the Round bit (see Section 4.5.1, “Execution Model for IEEE Operations” on page 119) participate in the shift with zeros shifted into the Round bit. The exponent is regarded as if its range were unlimited.

After normalization, or if normalization was not required, the intermediate result may have a nonzero significand and an exponent value that is less than the minimum value that can be represented in the format specified for the result. In this case, the intermediate result is said to be “Tiny” and the stored result is determined by the rules described in Section 4.4.4, “Underflow Exception”. These rules may require denormalization.

A number is denormalized by shifting its significand right while incrementing its exponent by 1 for each bit shifted, until the exponent is equal to the format’s minimum value. If any significant bits are lost in this shifting process then “Loss of Accuracy” has occurred (See Section 4.4.4, “Underflow Exception” on page 118) and Underflow Exception is signaled.

4.3.5 Data Handling and Precision

Most of the *Floating-Point Facility Architecture*, including all computational, *Move*, and *Select* instructions, use the floating-point double format to represent data in the FPRs. Single-precision and integer-valued operands may be manipulated using double-precision operations. Instructions are provided to coerce these values from a double format operand. Instructions are also provided for manipulations which do not require double-precision. In addition, instructions are provided to

access a true single-precision representation in storage, and a fixed-point integer representation in GPRs.

4.3.5.1 Single-Precision Operands

For single format data, a format conversion from single to double is performed when loading from storage into an FPR and a format conversion from double to single is performed when storing from an FPR to storage. No floating-point exceptions are caused by these instructions. An instruction is provided to explicitly convert a double format operand in an FPR to single-precision. Floating-point single-precision is enabled with four types of instruction.

1. Load Floating-Point Single

This form of instruction accesses a single-precision operand in single format in storage, converts it to double format, and loads it into an FPR. No floating-point exceptions are caused by these instructions.

2. Round to Floating-Point Single-Precision

The Floating Round to Single-Precision instruction rounds a double-precision operand to single-precision, checking the exponent for single-precision range and handling any exceptions according to respective enable bits, and places that operand into an FPR in double format. For results produced by single-precision arithmetic instructions, single-precision loads, and other instances of the Floating Round to Single-Precision instruction, this operation does not alter the value.

3. Single-Precision Arithmetic Instructions

This form of instruction takes operands from the FPRs in double format, performs the operation as if it produced an intermediate result having infinite precision and unbounded exponent range, and then coerces this intermediate result to fit in single format. Status bits, in the FPSCR and optionally in the Condition Register, are set to reflect the single-precision result. The result is then converted to double format and placed into an FPR. The result lies in the range supported by the single format.

All input values must be representable in single format; if they are not, the result placed into the target FPR, and the setting of status bits in the FPSCR and in the Condition Register (if Rc=1), are undefined.

4. Store Floating-Point Single

This form of instruction converts a double-precision operand to single format and stores that operand into storage. No floating-point exceptions are caused by these instructions. (The value being stored is effectively assumed to be the result of an instruction of one of the preceding three types.)

When the result of a *Load Floating-Point Single*, *Floating Round to Single-Precision*, or single-precision arithmetic instruction is stored in an FPR, the low-order 29 FRACTION bits are zero.

Programming Note

The *Floating Round to Single-Precision* instruction is provided to allow value conversion from double-precision to single-precision with appropriate exception checking and rounding. This instruction should be used to convert double-precision floating-point values (produced by double-precision load and arithmetic instructions and by *fcfid*) to single-precision values prior to storing them into single format storage elements or using them as operands for single-precision arithmetic instructions. Values produced by single-precision load and arithmetic instructions are already single-precision values and can be stored directly into single format storage elements, or used directly as operands for single-precision arithmetic instructions, without preceding the store, or the arithmetic instruction, by a *Floating Round to Single-Precision* instruction.

Programming Note

A single-precision value can be used in double-precision arithmetic operations. The reverse is true only if the double-precision value is representable in single format.

Some implementations may execute single-precision arithmetic instructions faster than double-precision arithmetic instructions. Therefore, if double-precision accuracy is not required, single-precision data and instructions should be used.

4.3.5.2 Integer-Valued Operands

Instructions are provided to round floating-point operands to integer values in floating-point format. To facilitate exchange of data between the floating-point and fixed-point facilities, instructions are provided to convert between floating-point double format and fixed-point integer format in an FPR. Computation on integer-valued operands may be performed using arithmetic instructions of the required precision. (The results may not be integer values.) The two groups of instructions provided specifically to support integer-valued operands are described below.

1. Floating Round to Integer

The *Floating Round to Integer* instructions round a double-precision operand to an integer value in floating-point double format. These instructions may cause Invalid Operation (VXSNAN) exceptions. See Sections 4.3.6 and 4.5.1 for more information about rounding.

2. Floating Convert To/From Integer

The *Floating Convert To Integer* instructions convert a double-precision operand to a 32-bit or 64-bit signed fixed-point integer format. Variants are provided both to perform rounding based on the value of $FPSCR_{RN}$ and to round toward zero. These instructions may cause Invalid Operation (VXSNAN, VXCVI) and Inexact exceptions. The *Floating Convert From Integer* instruction converts a 64-bit signed fixed-point integer to a double-precision floating-point integer. Because of the limitations of the source format, only an Inexact exception may be generated.

4.3.6 Rounding

The material in this section applies to operations that have numeric operands (i.e., operands that are not infinities or NaNs). Rounding the intermediate result of such an operation may cause an Overflow Exception, an Underflow Exception, or an Inexact Exception. The remainder of this section assumes that the operation causes no exceptions and that the result is numeric. See Section 4.3.2, “Value Representation” and Section 4.4, “Floating-Point Exceptions” for the cases not covered here.

The *Arithmetic* and *Rounding and Conversion* instructions round their intermediate results. With the exception of the *Estimate* instructions, these instructions produce an intermediate result that can be regarded as having infinite precision and unbounded exponent range. All but two groups of these instructions normalize or denormalize the intermediate result prior to rounding and then place the final result into the target FPR in double format. The *Floating Round to Integer* and *Floating Convert To Integer* instructions with biased exponents ranging from 1022 through 1074 are prepared for rounding by repetitively shifting the significant right one position and incrementing the biased exponent until it reaches a value of 1075. (Intermediate results with biased exponents 1075 or larger are already integers, and with biased exponents 1021 or less round to zero.) After rounding, the final result for *Floating Round to Integer* is normalized and put in double format, and for *Floating Convert To Integer* is converted to a signed fixed-point integer.

FPSCR bits FR and FI generally indicate the results of rounding. Each of the instructions which rounds its intermediate result sets these bits. If the fraction is incremented during rounding then FR is set to 1, otherwise FR is set to 0. If the result is inexact then FI is set to 1, otherwise FI is set to zero. The *Round to Integer* instructions are exceptions to this rule, setting FR and FI to 0. The *Estimate* instructions set FR and FI to undefined values. The remaining floating-point instructions do not alter FR and FI.

Four user-selectable rounding modes are provided through the Floating-Point Rounding Control field in the

FPSCR. See Section 4.2.2, “Floating-Point Status and Control Register”. These are encoded as follows.

RN	Rounding Mode
00	Round to Nearest
01	Round toward Zero
10	Round toward +Infinity
11	Round toward -Infinity

Let Z be the intermediate arithmetic result or the operand of a convert operation. If Z can be represented exactly in the target format, then the result in all rounding modes is Z as represented in the target format. If Z cannot be represented exactly in the target format, let $Z1$ and $Z2$ bound Z as the next larger and next smaller numbers representable in the target format. Then $Z1$ or $Z2$ can be used to approximate the result in the target format.

Figure 55 shows the relation of Z , $Z1$, and $Z2$ in this case. The following rules specify the rounding in the four modes. “LSB” means “least significant bit”.

Figure 55. Selection of $Z1$ and $Z2$

Round to Nearest

Choose the value that is closer to Z ($Z1$ or $Z2$). In case of a tie, choose the one that is even (least significant bit 0).

Round toward Zero

Choose the smaller in magnitude ($Z1$ or $Z2$).

Round toward +Infinity

Choose $Z1$.

Round toward -Infinity

Choose $Z2$.

See Section 4.5.1, “Execution Model for IEEE Operations” on page 119 for a detailed explanation of rounding.

4.4 Floating-Point Exceptions

This architecture defines the following floating-point exceptions:

- Invalid Operation Exception
 - SNaN
 - Infinity-Infinity
 - Infinity÷Infinity
 - Zero÷Zero
 - Infinity×Zero
 - Invalid Compare
 - Software-Defined Condition
 - Invalid Square Root
 - Invalid Integer Convert
- Zero Divide Exception
- Overflow Exception
- Underflow Exception
- Inexact Exception

These exceptions, other than Invalid Operation Exception due to Software-Defined Condition, may occur during execution of computational instructions. An Invalid Operation Exception due to Software-Defined Condition occurs when a *Move To FPSCR* instruction sets $FPSCR_{VXSOFT}$ to 1.

Each floating-point exception, and each category of Invalid Operation Exception, has an exception bit in the FPSCR. In addition, each floating-point exception has a corresponding enable bit in the FPSCR. The exception bit indicates occurrence of the corresponding exception. If an exception occurs, the corresponding enable bit governs the result produced by the instruction and, in conjunction with the FE0 and FE1 bits (see page 115), whether and how the system floating-point enabled exception error handler is invoked. (In general, the enabling specified by the enable bit is of invoking the system error handler, not of permitting the exception to occur. The occurrence of an exception depends only on the instruction and its inputs, not on the setting of any control bits. The only deviation from this general rule is that the occurrence of an Underflow Exception may depend on the setting of the enable bit.)

A single instruction, other than *mtfsfi* or *mtfsf*, may set more than one exception bit only in the following cases:

- Inexact Exception may be set with Overflow Exception.
- Inexact Exception may be set with Underflow Exception.
- Invalid Operation Exception (SNaN) is set with Invalid Operation Exception ($\infty \times 0$) for *Multiply-Add* instructions for which the values being multiplied are infinity and zero and the value being added is an SNaN.
- Invalid Operation Exception (SNaN) may be set with Invalid Operation Exception (Invalid Compare) for *Compare Ordered* instructions.
- Invalid Operation Exception (SNaN) may be set with Invalid Operation Exception (Invalid Integer Convert) for *Convert To Integer* instructions.

When an exception occurs the writing of a result to the target register may be suppressed or a result may be delivered, depending on the exception.

The writing of a result to the target register is suppressed for the following kinds of exception, so that there is no possibility that one of the operands is lost:

- Enabled Invalid Operation
- Enabled Zero Divide

For the remaining kinds of exception, a result is generated and written to the destination specified by the instruction causing the exception. The result may be a different value for the enabled and disabled conditions for some of these exceptions. The kinds of exception that deliver a result are the following:

- Disabled Invalid Operation
- Disabled Zero Divide
- Disabled Overflow
- Disabled Underflow
- Disabled Inexact
- Enabled Overflow
- Enabled Underflow
- Enabled Inexact

Subsequent sections define each of the floating-point exceptions and specify the action that is taken when they are detected.

The IEEE standard specifies the handling of exceptional conditions in terms of “traps” and “trap handlers”. In this architecture, an FPSCR exception enable bit of 1 causes generation of the result value specified in the IEEE standard for the “trap enabled” case; the expectation is that the exception will be detected by software, which will revise the result. An FPSCR exception enable bit of 0 causes generation of the “default result” value specified for the “trap disabled” (or “no trap occurs” or “trap is not implemented”) case; the expectation is that the exception will not be detected by software, which will simply use the default result. The result to be delivered in each case for each exception is described in the sections below.

The IEEE default behavior when an exception occurs is to generate a default value and not to notify software. In this architecture, if the IEEE default behavior when an exception occurs is desired for all exceptions, all FPSCR exception enable bits should be set to 0 and Ignore Exceptions Mode (see below) should be used. In this case the system floating-point enabled exception error handler is not invoked, even if floating-point exceptions occur: software can inspect the FPSCR exception bits if necessary, to determine whether exceptions have occurred.

In this architecture, if software is to be notified that a given kind of exception has occurred, the corresponding FPSCR exception enable bit must be set to 1 and a mode other than Ignore Exceptions Mode must be used. In this case the system floating-point enabled exception error handler is invoked if an enabled float-

ing-point exception occurs. The system floating-point enabled exception error handler is also invoked if a *Move To FPSCR* instruction causes an exception bit and the corresponding enable bit both to be 1; the *Move To FPSCR* instruction is considered to cause the enabled exception.

The FE0 and FE1 bits control whether and how the system floating-point enabled exception error handler is invoked if an enabled floating-point exception occurs. The location of these bits and the requirements for altering them are described in Book III. (The system floating-point enabled exception error handler is never invoked because of a disabled floating-point exception.) The effects of the four possible settings of these bits are as follows.

FE0	FE1	Description
0	0	Ignore Exceptions Mode Floating-point exceptions do not cause the system floating-point enabled exception error handler to be invoked.
0	1	Imprecise Nonrecoverable Mode The system floating-point enabled exception error handler is invoked at some point at or beyond the instruction that caused the enabled exception. It may not be possible to identify the excepting instruction or the data that caused the exception. Results produced by the excepting instruction may have been used by or may have affected subsequent instructions that are executed before the error handler is invoked.
1	0	Imprecise Recoverable Mode The system floating-point enabled exception error handler is invoked at some point at or beyond the instruction that caused the enabled exception. Sufficient information is provided to the error handler that it can identify the excepting instruction and the operands, and correct the result. No results produced by the excepting instruction have been used by or have affected subsequent instructions that are executed before the error handler is invoked.
1	1	Precise Mode The system floating-point enabled exception error handler is invoked precisely at the instruction that caused the enabled exception.

In all cases, the question of whether a floating-point result is stored, and what value is stored, is governed by the FPSCR exception enable bits, as described in subsequent sections, and is not affected by the value of the FE0 and FE1 bits.

In all cases in which the system floating-point enabled exception error handler is invoked, all instructions

before the instruction at which the system floating-point enabled exception error handler is invoked have completed, and no instruction after the instruction at which the system floating-point enabled exception error handler is invoked has begun execution. The instruction at which the system floating-point enabled exception error handler is invoked has completed if it is the excepting instruction and there is only one such instruction. Otherwise it has not begun execution (or may have been partially executed in some cases, as described in Book III).

Programming Note

In any of the three non-Precise modes, a *Floating-Point Status and Control Register* instruction can be used to force any exceptions, due to instructions initiated before the *Floating-Point Status and Control Register* instruction, to be recorded in the FPSCR. (This forcing is superfluous for Precise Mode.)

In either of the Imprecise modes, a *Floating-Point Status and Control Register* instruction can be used to force any invocations of the system floating-point enabled exception error handler, due to instructions initiated before the *Floating-Point Status and Control Register* instruction, to occur. (This forcing has no effect in Ignore Exceptions Mode, and is superfluous for Precise Mode.)

The last sentence of the paragraph preceding this Programming Note can apply only in the Imprecise modes, or if the mode has just been changed from Ignore Exceptions Mode to some other mode. (It always applies in the latter case.)

In order to obtain the best performance across the widest range of implementations, the programmer should obey the following guidelines.

- If the IEEE default results are acceptable to the application, Ignore Exceptions Mode should be used with all FPSCR exception enable bits set to 0.
- If the IEEE default results are not acceptable to the application, Imprecise Nonrecoverable Mode should be used, or Imprecise Recoverable Mode if recoverability is needed, with FPSCR exception enable bits set to 1 for those exceptions for which the system floating-point enabled exception error handler is to be invoked.
- Ignore Exceptions Mode should not, in general, be used when any FPSCR exception enable bits are set to 1.
- Precise Mode may degrade performance in some implementations, perhaps substantially, and therefore should be used only for debugging and other specialized applications.

4.4.1 Invalid Operation Exception

4.4.1.1 Definition

An Invalid Operation Exception occurs when an operand is invalid for the specified operation. The invalid operations are:

- Any floating-point operation on a Signaling NaN (SNaN)
- For add or subtract operations, magnitude subtraction of infinities ($\infty - \infty$)
- Division of infinity by infinity ($\infty \div \infty$)
- Division of zero by zero ($0 \div 0$)
- Multiplication of infinity by zero ($\infty \times 0$)
- Ordered comparison involving a NaN (Invalid Compare)
- Square root or reciprocal square root of a negative (and nonzero) number (Invalid Square Root)
- Integer convert involving a number too large in magnitude to be represented in the target format, or involving an infinity or a NaN (Invalid Integer Convert)

An Invalid Operation Exception also occurs when an *mtfsfi*, *mtfsf*, or *mtfsb1* instruction is executed that sets $\text{FPSCR}_{\text{VXSOFT}}$ to 1 (Software-Defined Condition).

4.4.1.2 Action

The action to be taken depends on the setting of the Invalid Operation Exception Enable bit of the FPSCR.

When Invalid Operation Exception is enabled ($\text{FPSCR}_{\text{VE}}=1$) and an Invalid Operation Exception occurs, the following actions are taken:

1. One or two Invalid Operation Exceptions are set

$\text{FPSCR}_{\text{VXSNAN}}$	(if SNaN)
$\text{FPSCR}_{\text{VXISI}}$	(if $\infty - \infty$)
$\text{FPSCR}_{\text{VXIDI}}$	(if $\infty \div \infty$)
$\text{FPSCR}_{\text{VXZDZ}}$	(if $0 \div 0$)
$\text{FPSCR}_{\text{VXIMZ}}$	(if $\infty \times 0$)
$\text{FPSCR}_{\text{VXVC}}$	(if invalid comp)
$\text{FPSCR}_{\text{VXSOFT}}$	(if sfw-def cond)
$\text{FPSCR}_{\text{VXSQRT}}$	(if invalid sqrt)
$\text{FPSCR}_{\text{VXCVI}}$	(if invalid int cvrt)
2. If the operation is an arithmetic, *Floating Round to Single-Precision*, *Floating Round to Integer*, or convert to integer operation,
 - the target FPR is unchanged
 - $\text{FPSCR}_{\text{FR FI}}$ are set to zero
 - $\text{FPSCR}_{\text{FPRF}}$ is unchanged
3. If the operation is a compare,
 - $\text{FPSCR}_{\text{FR FIC}}$ are unchanged
 - $\text{FPSCR}_{\text{FPCC}}$ is set to reflect unordered
4. If an *mtfsfi*, *mtfsf*, or *mtfsb1* instruction is executed that sets $\text{FPSCR}_{\text{VXSOFT}}$ to 1,
 - The FPSCR is set as specified in the instruction description.

When Invalid Operation Exception is disabled ($FPSCR_{VE}=0$) and an Invalid Operation Exception occurs, the following actions are taken:

1. One or two Invalid Operation Exceptions are set

$FPSCR_{VXSNAN}$	(if SNaN)
$FPSCR_{VXISI}$	(if $\infty - \infty$)
$FPSCR_{VXIDI}$	(if $\infty \div \infty$)
$FPSCR_{VXZDZ}$	(if $0 \div 0$)
$FPSCR_{VXIMZ}$	(if $\infty \times 0$)
$FPSCR_{VXVC}$	(if invalid comp)
$FPSCR_{VXSOF}$	(if sfw-def cond)
$FPSCR_{VXSQRT}$	(if invalid sqrt)
$FPSCR_{VXCVI}$	(if invalid int cvrt)
2. If the operation is an arithmetic or *Floating Round to Single-Precision* operation, the target FPR is set to a Quiet NaN
 $FPSCR_{FR FI}$ are set to zero
 $FPSCR_{FPRF}$ is set to indicate the class of the result (Quiet NaN)
3. If the operation is a convert to 64-bit integer operation, the target FPR is set as follows:
 FRT is set to the most positive 64-bit integer if the operand in FRB is a positive number or $+\infty$, and to the most negative 64-bit integer if the operand in FRB is a negative number, $-\infty$, or NaN
 $FPSCR_{FR FI}$ are set to zero
 $FPSCR_{FPRF}$ is undefined
4. If the operation is a convert to 32-bit integer operation, the target FPR is set as follows:
 $FRT_{0:31} \leftarrow$ undefined
 $FRT_{32:63}$ are set to the most positive 32-bit integer if the operand in FRB is a positive number or $+\infty$, and to the most negative 32-bit integer if the operand in FRB is a negative number, $-\infty$, or NaN
 $FPSCR_{FR FI}$ are set to zero
 $FPSCR_{FPRF}$ is undefined
5. If the operation is a compare, $FPSCR_{FR FI C}$ are unchanged
 $FPSCR_{FPCC}$ is set to reflect unordered
6. If an *mtfsfi*, *mtfsf*, or *mtfsb1* instruction is executed that sets $FPSCR_{VXSOF}$ to 1, The FPSCR is set as specified in the instruction description.

4.4.2 Zero Divide Exception

4.4.2.1 Definition

A Zero Divide Exception occurs when a *Divide* instruction is executed with a zero divisor value and a finite nonzero dividend value. It also occurs when a *Reciprocal Estimate* instruction (*fre[s]* or *frsqrt[s]*) is executed with an operand value of zero.

4.4.2.2 Action

The action to be taken depends on the setting of the Zero Divide Exception Enable bit of the FPSCR.

When Zero Divide Exception is enabled ($FPSCR_{ZE}=1$) and a Zero Divide Exception occurs, the following actions are taken:

1. Zero Divide Exception is set
 $FPSCR_{ZX} \leftarrow 1$
2. The target FPR is unchanged
3. $FPSCR_{FR FI}$ are set to zero
4. $FPSCR_{FPRF}$ is unchanged

When Zero Divide Exception is disabled ($FPSCR_{ZE}=0$) and a Zero Divide Exception occurs, the following actions are taken:

1. Zero Divide Exception is set
 $FPSCR_{ZX} \leftarrow 1$
2. The target FPR is set to \pm Infinity, where the sign is determined by the XOR of the signs of the operands
3. $FPSCR_{FR FI}$ are set to zero
4. $FPSCR_{FPRF}$ is set to indicate the class and sign of the result (\pm Infinity)

4.4.3 Overflow Exception

4.4.3.1 Definition

An Overflow Exception occurs when the magnitude of what would have been the rounded result if the exponent range were unbounded exceeds that of the largest finite number of the specified result precision.

4.4.3.2 Action

The action to be taken depends on the setting of the Overflow Exception Enable bit of the FPSCR.

When Overflow Exception is enabled ($FPSCR_{OE}=1$) and an Overflow Exception occurs, the following actions are taken:

1. Overflow Exception is set
 $FPSCR_{OX} \leftarrow 1$
2. For double-precision arithmetic instructions, the exponent of the normalized intermediate result is adjusted by subtracting 1536
3. For single-precision arithmetic instructions and the *Floating Round to Single-Precision* instruction, the exponent of the normalized intermediate result is adjusted by subtracting 192
4. The adjusted rounded result is placed into the target FPR
5. $FPSCR_{FPRF}$ is set to indicate the class and sign of the result (\pm Normal Number)

When Overflow Exception is disabled ($FPSCR_{OE}=0$) and an Overflow Exception occurs, the following actions are taken:

1. Overflow Exception is set
 $FPSCR_{OX} \leftarrow 1$
2. Inexact Exception is set
 $FPSCR_{XX} \leftarrow 1$
3. The result is determined by the rounding mode ($FPSCR_{RN}$) and the sign of the intermediate result as follows:
 - Round to Nearest
 Store \pm Infinity, where the sign is the sign of the intermediate result
 - Round toward Zero
 Store the format's largest finite number with the sign of the intermediate result
 - Round toward + Infinity
 For negative overflow, store the format's most negative finite number; for positive overflow, store +Infinity
 - Round toward - Infinity
 For negative overflow, store -Infinity; for positive overflow, store the format's largest finite number
4. The result is placed into the target FPR
5. $FPSCR_{FR}$ is undefined
6. $FPSCR_{FI}$ is set to 1
7. $FPSCR_{FPRF}$ is set to indicate the class and sign of the result (\pm Infinity or \pm Normal Number)

4.4.4 Underflow Exception

4.4.4.1 Definition

Underflow Exception is defined separately for the enabled and disabled states:

- Enabled:
 Underflow occurs when the intermediate result is "Tiny".
- Disabled:
 Underflow occurs when the intermediate result is "Tiny" and there is "Loss of Accuracy".

A "Tiny" result is detected before rounding, when a nonzero intermediate result computed as though both the precision and the exponent range were unbounded would be less in magnitude than the smallest normalized number.

If the intermediate result is "Tiny" and Underflow Exception is disabled ($FPSCR_{UE}=0$) then the intermediate result is denormalized (see Section 4.3.4, "Normalization and Denormalization" on page 112) and rounded (see Section 4.3.6, "Rounding" on page 113) before being placed into the target FPR.

"Loss of Accuracy" is detected when the delivered result value differs from what would have been computed were both the precision and the exponent range unbounded.

4.4.4.2 Action

The action to be taken depends on the setting of the Underflow Exception Enable bit of the FPSCR.

When Underflow Exception is enabled ($FPSCR_{UE}=1$) and an Underflow Exception occurs, the following actions are taken:

1. Underflow Exception is set
 $FPSCR_{UX} \leftarrow 1$
2. For double-precision arithmetic instructions, the exponent of the normalized intermediate result is adjusted by adding 1536
3. For single-precision arithmetic instructions and the *Floating Round to Single-Precision* instruction, the exponent of the normalized intermediate result is adjusted by adding 192
4. The adjusted rounded result is placed into the target FPR
5. $FPSCR_{FPRF}$ is set to indicate the class and sign of the result (\pm Normalized Number)

Programming Note

The FR and FI bits are provided to allow the system floating-point enabled exception error handler, when invoked because of an Underflow Exception, to simulate a “trap disabled” environment. That is, the FR and FI bits allow the system floating-point enabled exception error handler to unround the result, thus allowing the result to be denormalized.

When Underflow Exception is disabled ($FPSCR_{UE}=0$) and an Underflow Exception occurs, the following actions are taken:

1. Underflow Exception is set
 $FPSCR_{UX} \leftarrow 1$
2. The rounded result is placed into the target FPR
3. $FPSCR_{FPFF}$ is set to indicate the class and sign of the result (\pm Normalized Number, \pm Denormalized Number, or \pm Zero)

4.4.5 Inexact Exception

4.4.5.1 Definition

An Inexact Exception occurs when one of two conditions occur during rounding:

1. The rounded result differs from the intermediate result assuming both the precision and the exponent range of the intermediate result to be unbounded. In this case the result is said to be inexact. (If the rounding causes an enabled Overflow Exception or an enabled Underflow Exception, an Inexact Exception also occurs only if the significands of the rounded result and the intermediate result differ.)
2. The rounded result overflows and Overflow Exception is disabled.

4.4.5.2 Action

The action to be taken does not depend on the setting of the Inexact Exception Enable bit of the FPSCR.

When an Inexact Exception occurs, the following actions are taken:

1. Inexact Exception is set
 $FPSCR_{XX} \leftarrow 1$
2. The rounded or overflowed result is placed into the target FPR
3. $FPSCR_{FPFF}$ is set to indicate the class and sign of the result

Programming Note

In some implementations, enabling Inexact Exceptions may degrade performance more than does enabling other types of floating-point exception.

4.5 Floating-Point Execution Models

All implementations of this architecture must provide the equivalent of the following execution models to ensure that identical results are obtained.

Special rules are provided in the definition of the computational instructions for the infinities, denormalized numbers and NaNs. The material in the remainder of this section applies to instructions that have numeric operands and a numeric result (i.e., operands and result that are not infinities or NaNs), and that cause no exceptions. See Section 4.3.2 and Section 4.4 for the cases not covered here.

Although the double format specifies an 11-bit exponent, exponent arithmetic makes use of two additional bits to avoid potential transient overflow conditions. One extra bit is required when denormalized double-precision numbers are prenormalized. The second bit is required to permit the computation of the adjusted exponent value in the following cases when the corresponding exception enable bit is 1:

- Underflow during multiplication using a denormalized operand.
- Overflow during division using a denormalized divisor.

The IEEE standard includes 32-bit and 64-bit arithmetic. The standard requires that single-precision arithmetic be provided for single-precision operands. The standard permits double-precision floating-point operations to have either (or both) single-precision or double-precision operands, but states that single-precision floating-point operations should not accept double-precision operands. The Power ISA follows these guidelines; double-precision arithmetic instructions can have operands of either or both precisions, while single-precision arithmetic instructions require all operands to be single-precision. Double-precision arithmetic instructions and *fcfid* produce double-precision values, while single-precision arithmetic instructions produce single-precision values.

For arithmetic instructions, conversions from double-precision to single-precision must be done explicitly by software, while conversions from single-precision to double-precision are done implicitly.

4.5.1 Execution Model for IEEE Operations

The following description uses 64-bit arithmetic as an example. 32-bit arithmetic is similar except that the FRACTION is a 23-bit field, and the single-precision Guard, Round, and Sticky bits (described in this section) are logically adjacent to the 23-bit FRACTION field.

IEEE-conforming significant arithmetic is considered to be performed with a floating-point accumulator having the following format, where bits 0:55 comprise the significand of the intermediate result.

Figure 56. IEEE 64-bit execution model

The S bit is the sign bit.

The C bit is the carry bit, which captures the carry out of the significand.

The L bit is the leading unit bit of the significand, which receives the implicit bit from the operand.

The FRACTION is a 52-bit field that accepts the fraction of the operand.

The Guard (G), Round (R), and Sticky (X) bits are extensions to the low-order bits of the accumulator. The G and R bits are required for postnormalization of the result. The G, R, and X bits are required during rounding to determine if the intermediate result is equally near the two nearest representable values. The X bit serves as an extension to the G and R bits by representing the logical OR of all bits that may appear to the low-order side of the R bit, due either to shifting the accumulator right or to other generation of low-order result bits. The G and R bits participate in the left shifts with zeros being shifted into the R bit. Figure 57 shows the significance of the G, R, and X bits with respect to the intermediate result (IR), the representable number next lower in magnitude (NL), and the representable number next higher in magnitude (NH).

G R X	Interpretation
0 0 0	IR is exact
0 0 1	IR closer to NL
0 1 0	
0 1 1	
1 0 0	IR midway between NL and NH
1 0 1	IR closer to NH
1 1 0	
1 1 1	

Figure 57. Interpretation of G, R, and X bits

Figure 58 shows the positions of the Guard, Round, and Sticky bits for double-precision and single-precision floating-point numbers relative to the accumulator illustrated in Figure 56.

Format	Guard	Round	Sticky
Double	G bit	R bit	X bit
Single	24	25	OR of 26:52, G, R, X

Figure 58. Location of the Guard, Round, and Sticky bits in the IEEE execution model

The significand of the intermediate result is prepared for rounding by shifting its contents right, if required, until the least significant bit to be retained is in the low-order bit position of the fraction. Four user-selectable rounding modes are provided through $FPSCR_{RN}$ as described in Section 4.3.6, “Rounding” on page 113. Using Z1 and Z2 as defined on page 113, the rules for rounding in each mode are as follows.

■ **Round to Nearest**

Guard bit = 0

The result is truncated. (Result exact (GRX=000) or closest to next lower value in magnitude (GRX=001, 010, or 011))

Guard bit = 1

Depends on Round and Sticky bits:

Case a

If the Round or Sticky bit is 1 (inclusive), the result is incremented. (Result closest to next higher value in magnitude (GRX=101, 110, or 111))

Case b

If the Round and Sticky bits are 0 (result midway between closest representable values), then if the low-order bit of the result is 1 the result is incremented. Otherwise (the low-order bit of the result is 0) the result is truncated (this is the case of a tie rounded to even).

■ **Round toward Zero**

Choose the smaller in magnitude of Z1 or Z2. If the Guard, Round, or Sticky bit is nonzero, the result is inexact.

■ **Round toward + Infinity**

Choose Z1.

■ **Round toward - Infinity**

Choose Z2.

If rounding results in a carry into C, the significand is shifted right one position and the exponent is incremented by one. This yields an inexact result, and possibly also exponent overflow. If any of the Guard, Round, or Sticky bits is nonzero, then the result is also inexact. Fraction bits are stored to the target FPR. For *Floating Round to Integer*, *Floating Round to Single-Precision*, and single-precision arithmetic instructions, low-order zeros must be appended as appropriate to fill out the double-precision fraction.

4.5.2 Execution Model for Multiply-Add Type Instructions

The Power ISA provides a special form of instruction that performs up to three operations in one instruction (a multiplication, an addition, and a negation). With this added capability comes the special ability to produce a more exact intermediate result as input to the rounder. 32-bit arithmetic is similar except that the FRACTION field is smaller.

Multiply-add significand arithmetic is considered to be performed with a floating-point accumulator having the following format, where bits 0:106 comprise the significand of the intermediate result.

Figure 59. Multiply-add 64-bit execution model

The first part of the operation is a multiplication. The multiplication has two 53-bit significands as inputs, which are assumed to be prenormalized, and produces a result conforming to the above model. If there is a carry out of the significand (into the C bit), then the significand is shifted right one position, shifting the L bit (leading unit bit) into the most significant bit of the FRACTION and shifting the C bit (carry out) into the L bit. All 106 bits (L bit, the FRACTION) of the product take part in the add operation. If the exponents of the two inputs to the adder are not equal, the significand of the operand with the smaller exponent is aligned (shifted) to the right by an amount that is added to that exponent to make it equal to the other input's exponent. Zeros are shifted into the left of the significand as it is aligned and bits shifted out of bit 105 of the significand are ORed into the X' bit. The add operation also produces a result conforming to the above model with the X' bit taking part in the add operation.

The result of the addition is then normalized, with all bits of the addition result, except the X' bit, participating in the shift. The normalized result serves as the intermediate result that is input to the rounder.

For rounding, the conceptual Guard, Round, and Sticky bits are defined in terms of accumulator bits. Figure 60 shows the positions of the Guard, Round, and Sticky bits for double-precision and single-precision floating-point numbers in the multiply-add execution model.

Format	Guard	Round	Sticky
Double	53	54	OR of 55:105, X'
Single	24	25	OR of 26:105, X'

Figure 60. Location of the Guard, Round, and Sticky bits in the multiply-add execution model

The rules for rounding the intermediate result are the same as those given in Section 4.5.1.

If the instruction is *Floating Negative Multiply-Add* or *Floating Negative Multiply-Subtract*, the final result is negated.

| 4.6 Floating-Point Facility Instructions

For each instruction in this section that defines the use of an Rc bit, the behavior defined for the instruction corresponding to Rc=1 is considered part of the Floating-Point.Record category.

4.6.1 Floating-Point Storage Access Instructions

The *Storage Access* instructions compute the effective address (EA) of the storage to be accessed as described in Section 1.10.3, “Effective Address Calculation” on page 27.

Programming Note

The *la* extended mnemonic permits computing an effective address as a *Load* or *Store* instruction would, but loads the address itself into a GPR rather than loading the value that is in storage at that address. This extended mnemonic is described in Section E.9, “Miscellaneous Mnemonics” on page 637.

4.6.1.1 Storage Access Exceptions

Storage accesses will cause the system data storage error handler to be invoked if the program is not allowed to modify the target storage (*Store* only), or if the program attempts to access storage that is unavailable.

4.6.2 Floating-Point Load Instructions

There are three basic forms of load instruction: single-precision, double-precision, and integer. The integer form is provided by the *Load Floating-Point as Integer Word Algebraic* instruction, described on page 126. Because the FPRs support only floating-point double format, single-precision *Load Floating-Point* instructions convert single-precision data to double format prior to loading the operand into the target FPR. The conversion and loading steps are as follows.

Let $WORD_{0:31}$ be the floating-point single-precision operand accessed from storage.

Normalized Operand

if $WORD_{1:8} > 0$ and $WORD_{1:8} < 255$ then

$$\begin{aligned} FRT_{0:1} &\leftarrow WORD_{0:1} \\ FRT_2 &\leftarrow \neg WORD_1 \\ FRT_3 &\leftarrow \neg WORD_1 \\ FRT_4 &\leftarrow \neg WORD_1 \\ FRT_{5:63} &\leftarrow WORD_{2:31} \parallel 29_0 \end{aligned}$$

Denormalized Operand

if $WORD_{1:8} = 0$ and $WORD_{9:31} \neq 0$ then

$$\begin{aligned} \text{sign} &\leftarrow WORD_0 \\ \text{exp} &\leftarrow -126 \\ \text{frac}_{0:52} &\leftarrow 0b0 \parallel WORD_{9:31} \parallel 29_0 \\ &\text{normalize the operand} \\ &\text{do while } \text{frac}_0 = 0 \\ &\quad \text{frac}_{0:52} \leftarrow \text{frac}_{1:52} \parallel 0b0 \end{aligned}$$

$$\begin{aligned} \text{exp} &\leftarrow \text{exp} - 1 \\ FRT_0 &\leftarrow \text{sign} \\ FRT_{1:11} &\leftarrow \text{exp} + 1023 \\ FRT_{12:63} &\leftarrow \text{frac}_{1:52} \end{aligned}$$

Zero / Infinity / NaN

if $WORD_{1:8} = 255$ or $WORD_{1:31} = 0$ then

$$\begin{aligned} FRT_{0:1} &\leftarrow WORD_{0:1} \\ FRT_2 &\leftarrow WORD_1 \\ FRT_3 &\leftarrow WORD_1 \\ FRT_4 &\leftarrow WORD_1 \\ FRT_{5:63} &\leftarrow WORD_{2:31} \parallel 29_0 \end{aligned}$$

For double-precision *Load Floating-Point* instructions and for the *Load Floating-Point as Integer Word Algebraic* instruction no conversion is required, as the data from storage are copied directly into the FPR.

Many of the *Load Floating-Point* instructions have an “update” form, in which register RA is updated with the effective address. For these forms, if $RA \neq 0$, the effective address is placed into register RA and the storage element (word or doubleword) addressed by EA is loaded into FRT.

Note: Recall that RA and RB denote General Purpose Registers, while FRT denotes a Floating-Point Register.

Load Floating-Point Single**D-form**

lfs FRT,D(RA)

0	48	FRT	RA	D	31
	6	11	16		

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + EXTS(D)
FRT ← DOUBLE(MEM(EA, 4))

```

Let the effective address (EA) be the sum (RA)0)+D.

The word in storage addressed by EA is interpreted as a floating-point single-precision operand. This word is converted to floating-point double format (see page 123) and placed into register FRT.

Special Registers Altered:

None

Load Floating-Point Single with Update**D-form**

lfsu FRT,D(RA)

0	49	FRT	RA	D	31
	6	11	16		

```

EA ← (RA) + EXTS(D)
FRT ← DOUBLE(MEM(EA, 4))
RA ← EA

```

Let the effective address (EA) be the sum (RA)+D.

The word in storage addressed by EA is interpreted as a floating-point single-precision operand. This word is converted to floating-point double format (see page 123) and placed into register FRT.

EA is placed into register RA.

If RA=0, the instruction form is invalid.

Special Registers Altered:

FRT ← 320 || MEM(EA, 4)
    
```

Let the effective address (EA) be the sum (RAI0)+(RB).

The word in storage addressed by EA is loaded into FRT_{32:63}. FRT_{0:31} are set to 0.

Special Registers Altered:
None

4.6.3 Floating-Point Store Instructions

There are three basic forms of store instruction: single-precision, double-precision, and integer. The integer form is provided by the *Store Floating-Point as Integer Word* instruction, described on page 130. Because the FPRs support only floating-point double format for floating-point data, single-precision *Store Floating-Point* instructions convert double-precision data to single format prior to storing the operand into storage. The conversion steps are as follows.

Let $WORD_{0:31}$ be the word in storage written to.

No Denormalization Required (includes Zero / Infinity / NaN)

if $FRS_{1:11} > 896$ or $FRS_{1:63} = 0$ then
 $WORD_{0:1} \leftarrow FRS_{0:1}$
 $WORD_{2:31} \leftarrow FRS_{5:34}$

Denormalization Required

if $874 \leq FRS_{1:11} \leq 896$ then
 $sign \leftarrow FRS_0$
 $exp \leftarrow FRS_{1:11} - 1023$
 $frac_{0:52} \leftarrow 0b1 \parallel FRS_{12:63}$
 denormalize operand
 do while $exp < -126$
 $frac_{0:52} \leftarrow 0b0 \parallel frac_{0:51}$
 $exp \leftarrow exp + 1$
 $WORD_0 \leftarrow sign$
 $WORD_{1:8} \leftarrow 0x00$
 $WORD_{9:31} \leftarrow frac_{1:23}$
 else $WORD \leftarrow undefined$

Notice that if the value to be stored by a single-precision *Store Floating-Point* instruction is larger in magnitude than the maximum number representable in single format, the first case above (No Denormalization Required) applies. The result stored in WORD is then a well-defined value, but is not numerically equal to the value in the source register (i.e., the result of a sin-

gle-precision *Load Floating-Point* from WORD will not compare equal to the contents of the original source register).

For double-precision *Store Floating-Point* instructions and for the *Store Floating-Point as Integer Word* instruction no conversion is required, as the data from the FPR are copied directly into storage.

Many of the *Store Floating-Point* instructions have an “update” form, in which register RA is updated with the effective address. For these forms, if $RA \neq 0$, the effective address is placed into register RA.

Note: Recall that RA and RB denote General Purpose Registers, while FRS denotes a Floating-Point Register.

Store Floating-Point Single D-form

stfs FRS,D(RA)

0	52	FRS	RA	D	31
	6	11	16		

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + EXTS(D)
MEM(EA, 4) ← SINGLE((FRS))

```

Let the effective address (EA) be the sum (RA)0)+D.

The contents of register FRS are converted to single format (see page 127) and stored into the word in storage addressed by EA.

Store Floating-Point as Integer Word Indexed X-form

stfiwx FRS,RA,RB

31	FRS	RA	RB	983	/
0	6	11	16	21	31

```
if RA = 0 then b ← 0
else        b ← (RA)
EA ← b + (RB)
MEM(EA, 4) ← (FRS)32:63
```

Let the effective address (EA) be the sum (RAI0)+(RB).

(FRS)_{32:63} are stored, without conversion, into the word in storage addressed by EA.

If the contents of register FRS were produced, either directly or indirectly, by a *Load Floating-Point Single* instruction, a single-precision *Arithmetic* instruction, or *frsp*, then the value stored is undefined. (The contents of register FRS are produced directly by such an instruction if FRS is the target register for the instruction. The contents of register FRS are produced indirectly by such an instruction if FRS is the final target register of a sequence of one or more *Floating-Point Move* instructions, with the input to the sequence having been produced directly by such an instruction.)

Special Registers Altered:

None

4.6.4 Floating-Point Load Store Doubleword Pair Instructions [Category: Floating-Point.Phased-Out]

For *lfdp[x]*, the doubleword-pair in storage addressed by EA is loaded into an even-odd pair of FPRs with the even-numbered FPR being loaded with the leftmost doubleword from storage and the odd-numbered FPR being loaded with the rightmost doubleword.

For *stfdp[x]*, the content of an even-odd pair of FPRs is stored into the doubleword-pair in storage addressed by EA, with the even-numbered FPR being stored into the leftmost doubleword in storage and the

odd-numbered FPR being stored into the rightmost doubleword.

Programming Note

The instructions described in this section should not be used to access an operand in DFP128 format when $MSR_{LE}=1$.

Load Floating-Point Double Pair DS-form

lfdp FRTp,DS(RA)

4.6.5 Floating-Point Move Instructions

These instructions copy data from one floating-point register to another, altering the sign bit (bit 0) as described below for *fneg*, *fabs*, *fnabs*, and *fcpsgn*. These instructions treat NaNs just like any other kind of

value (e.g., the sign bit of a NaN may be altered by *fneg*, *fabs*, *fnabs*, and *fcpsgn*). These instructions do not alter the FPSCR.

fadds. FRT,FRA,FRB (Rc=1)

0	59	FRT	FRA	FRB	///	21	Rc
		6	11	16	21	26	31

The floating-point operand in register FRA is added to the floating-point operand in register FRB.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of the Floating-Point Rounding Control field RN of the FPSCR and placed into register FRT.

Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.

If a carry occurs, the sum's significand is shifted right one bit position and the exponent is increased by one.

FPSCR_{FPRF} is set to the class and sign of the result, except for Invalid Operation Exceptions when FPSCR_{VE}=1.

Programming Note

For the *Floating-Point Estimate* instructions, some implementations might implement a precision higher than the minimum architected precision. Thus, a program may take advantage of the higher precision instructions to increase performance by decreasing the iterations needed for software emulation of floating-point instructions. However, there is no guarantee given about the precision which may vary (up or down) between implementations. Only programs targeted at a specific implementation (i.e., the program will not be migrated to another implementation) should take advantage of the higher precision of the instructions. All other programs should rely on the minimum architected precision, which will guarantee the program to run properly across different implementations.

Programming Note

ftdiv and **ftsqr** are provided to accelerate software emulation of divide and square root operations, by performing the requisite special case checking. Software needs only a single branch, on FE=1 (in CR[BF]), to a special case handler. FG and FL may provide further acceleration opportunities.

4.6.6.2 Floating-Point Multiply-Add Instructions

These instructions combine a multiply and an add operation without an intermediate rounding operation. The fraction part of the intermediate product is 106 bits wide (L bit, FRACTION), and all 106 bits take part in the add/subtract portion of the instruction.

Status bits are set as follows.

- Overflow, Underflow, and Inexact Exception bits, the FR and FI bits, and the FPRF field are set

based on the final result of the operation, and not on the result of the multiplication.

- Invalid Operation Exception bits are set as if the multiplication and the addition were performed using two separate instructions (*fmul[s]*, followed by *fadd[s]* or *fsub[s]*). That is, multiplication of infinity by 0 or of anything by an SNaN, and/or addition of an SNaN, cause the corresponding exception bits to be set.

4.6.7.3 Floating Round to Integer Instructions

The *Floating Round to Integer* instructions provide direct support for rounding functions found in high level languages. For example, *frin*, *friz*, *frip*, and *frim* implement C++ round(), trunc(), ceil(), and floor(), respectively. Note that *frin* does not implement the IEEE Round to Nearest function, which is often further described as “ties to even.” The rounding performed by these instructions is described fully in Section A.4, “Floating-Point Round to Integer Model” on page 612.

Programming Note

These instructions set FPSCR_{FR FI} to 0b00 regardless of whether the result is inexact or rounded because there is a desire to preserve the value of FPSCR_{XX}. Furthermore, it is believed that most programs do not need to know whether these rounding operations produce inexact or rounded results. If it is necessary to determine whether the result is inexact or rounded, software must compare the result with the original source operand.

Floating Round to Integer Nearest X-form

frin FRT,FRB (Rc=0)
 frin. FRT,FRB (Rc=1)

0	63	FRT	///	FRB	392	Rc
		6	11	16	21	31

The floating-point operand in register FRB is rounded to an integral value as follows, with the result placed into register FRT. If the sign of the operand is positive, (FRB) + 0.5 is truncated to an integral value, otherwise (FRB) - 0.5 is truncated to an integral value.

FPSCR_{FPRF} is set to the class and sign of the result, except for Invalid Operation Exceptions when FPSCR_{VE} = 1.

Special Registers Altered:

The floating-point operand in register FRB is rounded to an integral value using the rounding mode round toward -infinity, and the result is placed into register FRT.

FPSCR_{FPRF} is set to the class and sign of the result, except for Invalid Operation Exceptions when FPSCR_{VE} = 1.

Special Registers Altered:

FPRF FR (set to 0) FI (set to 0)
 FX
 VXSNaN
 CR1 (if Rc = 1)

4.6.8 Floating-Point Compare Instructions

The floating-point *Compare* instructions compare the contents of two floating-point registers. Comparison ignores the sign of zero (i.e., regards +0 as equal to -0). The comparison can be ordered or unordered.

The comparison sets one bit in the designated CR field to 1 and the other three to 0. The FPCC is set in the same way.

The CR field and the FPCC are set as follows.

Bit	Name	Description
0	FL	(FRA) < (FRB)
1	FG	(FRA) > (FRB)
2	FE	(FRA) = (FRB)
3	FU	(FRA) ? (FRB) (unordered)

Floating Compare Unordered

X-form

fcm_{pu} BF,FRA,FRB

63	BF	//	FRA	FRB	0	/
0	6	9	11	16	21	31

```

if (FRA) is a NaN or
(FRB) is a NaN then c ← 0b0001
else if (FRA) < (FRB) then c ← 0b1000
else if (FRA) > (FRB) then c ← 0b0100
else
c ← 0b0010
FPCC ← c
CR4×BF:4×BF+3 ← c
if (FRA) is an SNaN or
(FRB) is an SNaN then
VXSNAN ← 1

```

The floating-point operand in register FRA is compared to the floating-point operand in register FRB. The result of the compare is placed into CR field BF and the FPCC.

If either of the operands is a NaN, either quiet or signaling, then CR field BF and the FPCC are set to reflect unordered. If either of the operands is a Signaling NaN, then VXSNAN is set.

Special Registers Altered:

CR field BF
FPCC
FX
VXSNAN

Floating Compare Ordered

X-form

fcm_{po} BF,FRA,FRB

63	BF	//	FRA	FRB	32	/
0	6	9	11	16	21	31

```

if (FRA) is a NaN or
(FRB) is a NaN then c ← 0b0001
else if (FRA) < (FRB) then c ← 0b1000
else if (FRA) > (FRB) then c ← 0b0100
else
c ← 0b0010
FPCC ← c
CR4×BF:4×BF+3 ← c
if (FRA) is an SNaN or
(FRB) is an SNaN then
VXSNAN ← 1
if VE = 0 then VXVC ← 1
else if (FRA) is a QNaN or
(FRB) is a QNaN then VXVC ← 1

```

The floating-point operand in register FRA is compared to the floating-point operand in register FRB. The result of the compare is placed into CR field BF and the FPCC.

If either of the operands is a NaN, either quiet or signaling, then CR field BF and the FPCC are set to reflect unordered. If either of the operands is a Signaling NaN, then VXSNAN is set and, if Invalid Operation is disabled (VE=0), VXVC is set. If neither operand is a Signaling NaN but at least one operand is a Quiet NaN, then VXVC is set.

Special Registers Altered:

CR field BF
FPCC
FX
VXSNAN VXVC

4.6.9 Floating-Point Select Instruction

Floating Select

A-form

fsel FRT,FRA,FRC,FRB (Rc=0)
fsel. FRT,FRA,FRC,FRB (Rc=1)

63	FRT	FRA	FRB	FRC	23	Rc
0	6	11	16	21	26	31

```
if (FRA) ≥ 0.0 then FRT ← (FRC)
else FRT ← (FRB)
```

The floating-point operand in register FRA is compared to the value zero. If the operand is greater than or equal to zero, register FRT is set to the contents of register FRC. If the operand is less than zero or is a NaN, register FRT is set to the contents of register FRB. The comparison ignores the sign of zero (i.e., regards +0 as equal to -0).

Special Registers Altered:

CR1 (if Rc=1)

Programming Note

Examples of uses of this instruction can be found in Sections F.2, “Floating-Point Conversions [Category: Floating-Point]” on page 644 and F.3, “Floating-Point Selection [Category: Floating-Point]” on page 648.

Warning: Care must be taken in using *fsel* if IEEE compatibility is required, or if the values being tested can be NaNs or infinities; see Section F.3.4, “Notes” on page 648.

Move To FPSCR Field Immediate X-form

mtfsfi BF,U,W (Rc=0)
 mtfsfi. BF,U,W (Rc=1)

63	BF	//	///	W	U	/	134	Rc
0	6	9	11	15	16	20	21	31

The value of the U field is placed into FPSCR field BF+8×(1-W).

FPSCR_{FX} is altered only if BF = 0 and W = 0.

Special Registers Altered:

FPSCR field BF + 8×(1-W)
 CR1 (if Rc=1)

Programming Note

mtfsfi serves as both a basic and an extended mnemonic. The Assembler will recognize a *mtfsfi* mnemonic with three operands as the basic form, and a *mtfsfi* mnemonic with two operands as the extended form. In the extended form the W operand is omitted and assumed to be 0.

Programming Note

When FPSCR_{32:35} is specified, bits 32 (FX) and 35 (OX) are set to the values of U₀ and U₃ (i.e., even if this instruction causes OX to change from 0 to 1, FX is set from U₀ and not by the usual rule that FX is set to 1 when an exception bit changes from 0 to 1). Bits 33 and 34 (FEX and VX) are set according to the usual rule, given on page 107, and not from U_{1:2}.

Move To FPSCR Fields**XFL-form**

mtfsf FLM,FRB,L,W (Rc=0)
 mtfsf. FLM,FRB,L,W (Rc=1)

63	L	FLM	W	FRB	711	Rc
0	6	7	15	16	21	31

The FPSCR is modified as specified by the FLM, L, and W fields.

L = 0

The contents of register FRB are placed into the FPSCR under control of the W field and the field mask specified by FLM. W and the field mask identify the 4-bit fields affected. Let i be an integer in the range 0-7. If FLM_i=1 then FPSCR field k is set to the contents of the corresponding field of register FRB, where k = i+8×(1-W).

L = 1

The contents of register FRB are placed into the FPSCR.

FPSCR_{FX} is not altered implicitly by this instruction.

Special Registers Altered:

FPSCR fields selected by mask, L, and W
 CR1 (if Rc=1)

Programming Note

mtfsf serves as both a basic and an extended mnemonic. The Assembler will recognize a *mtfsf* mnemonic with four operands as the basic form, and a *mtfsf* mnemonic with two operands as the extended form. In the extended form the W and L operands are omitted and both are assumed to be 0.

Programming Note

Updating fewer than eight fields of the FPSCR may have substantially poorer performance on some implementations than updating eight fields or all of the fields.

Programming Note

If L=1 or if L=0 and FPSCR_{32:35} is specified, bits 32 (FX) and 35 (OX) are set to the values of (FRB)₃₂ and (FRB)₃₅ (i.e., even if this instruction causes OX to change from 0 to 1, FX is set from (FRB)₃₂ and not by the usual rule that FX is set to 1 when an exception bit changes from 0 to 1). Bits 33 and 34 (FEX and VX) are set according to the usual rule, given on page 107, and not from (FRB)_{33:34}.

Move To FPSCR Bit 0

X-form

mtfsb0 BT (Rc=0)
 mtfsb0. BT (Rc=1)

Bit BT+32 of the FPSCR is set to 0.

Special Registers Altered:

FPSCR bit BT+32
 CR1 (if Rc=1)

Programming Note

Bits 33 and 34 (FEX and VX) cannot be explicitly reset.

Move To FPSCR Bit 1

X-form

mtfsb1 BT (Rc=0)
 mtfsb1. BT (Rc=1)

Bit BT+32 of the FPSCR is set to 1.

Special Registers Altered:

FPSCR bits BT+32 and FX
 CR1 (if Rc=1)

Programming Note

Bits 32 and 34 (FEX and VX) cannot be explicitly set.

5.1 Decimal Floating-Point (DFP) Facility Overview

This chapter describes the behavior of the decimal floating-point facility, the supported data types, formats, and classes, and the usage of registers. Also included are the execution model, exceptions, and instructions supported by the decimal floating-point facility.

The decimal floating-point (DFP) facility shares the 32 floating-point registers (FPRs) and the Floating-Point Status and Control Register (FPSCR) with the floating-point (BFP) facility. However, the interpretation of data formats in the FPRs, and the meaning of some control and status bits in the FPSCR are different between the BFP and DFP facilities.

The DFP facility also shares the Condition Register (CR) with the fixed-Point facility, the BFP facility, and the vector facility.

The DFP facility supports three DFP data formats: DFP Short (single precision), DFP Long (double precision), and DFP Extended (quad precision). Most operations are performed on DFP Long or DFP Extended format directly. Support for DFP Short is limited to conversion to and from DFP Long. Some DFP instructions operate on other data types, including signed or unsigned binary fixed-point data, and signed or unsigned decimal data.

DFP instructions are provided to perform arithmetic, compare, test, quantum-adjustment, conversion, and format operations on operands held in FPRs or FPR pairs.

- Arithmetic instructions
These instructions perform addition, subtraction, multiplication, and division operations.
- Compare instructions
These instructions perform a comparison operation on the numerical value of two DFP operands.
- Test instructions
These instructions test the data class, the data group, the exponent, or the number of significant digits of a DFP operand.
- Quantum-adjustment instructions
These instructions convert a DFP number to a result in the form that has the designated exponent, which may be explicitly or implicitly specified.
- Conversion instructions
These instructions perform conversion between different data formats or data types.
- Format instructions
These instructions facilitate composing or decomposing a DFP operand.

These instructions are described in Section 5.6 “DFP Instruction Descriptions” on page 172.

The three DFP data formats allow finite numbers to be represented with different precision and ranges. Special codes are also provided to represent +Infinity, -Infinity, Quiet NaN (Not-a-Number), and Signaling NaN. Operations involving infinities produce results obeying traditional mathematical conventions. NaNs have no mathematical interpretation. The encoding of NaNs provides a diagnostic information field. This diagnostic field may be used to indicate such things as the source of an uninitialized variable or the reason an invalid result was produced.

The DFP processor recognizes a set of DFP exceptions which are indicated via bits set in the FPSCR. Additionally, the DFP exception actions depend on the setting of the various exception enable bits in the FPSCR.

The following DFP exceptions are detected by the DFP processor. The exception status bits in the FPSCR are indicated in parentheses.

- Invalid Operation Exception (VX)
 - SNaN (VXSNAN)
 - $\infty - \infty$ (VXISI)
 - $\infty \div \infty$ (VXIDI)
 - $0 \div 0$ (VXZDZ)
 - $\infty \times 0$ (VXIMZ)
 - Invalid Compare (VXVC)
 - Invalid conversion (VXCVI)
- Zero Divide Exception (ZX)
- Overflow Exception (OX)
- Underflow Exception (UX)

- Inexact Exception (XX)

Each DFP exception and each category of Invalid Operation Exception has an exception status bit in the FPSCR. In addition, each of the five DFP exceptions has a corresponding enable bit in the FPSCR. These enable bits enable or disable the invocation of the system floating-point enabled exception error handler, and may affect the setting of some exception status bits in the FPSCR.

The usage of these bits by the DFP facility differs from the usage by the BFP facility. Section 5.5.10 “DFP Exceptions” on page 164 provides a detailed discussion of DFP exceptions, including the effects of the enable bits.

5.2 DFP Register Handling

The following sections describe first how the floating-point registers are utilized by the DFP facility. The subsequent section covers the DFP usage of CR and FPSCR.

5.2.1 DFP Usage of Floating-Point Registers

The DFP facility shares the same 32 64-bit FPRs with the BFP facility. Like the FP instructions, DFP instructions also use 5-bit fields for designating the FPRs to hold the source or target operands.

When data in DFP Short format is held in a FPR, it occupies the rightmost 32 bits of the FPR. The *Load Floating-Point as Integer Word Algebraic* instruction is provided to load the rightmost 32 bits of a FPR with a single-word data from storage. The *Store Floating-Point as Integer Word* instruction is available to store the rightmost 32 bits of a FPR to a storage location.

Data in DFP Long format, 64-bit binary fixed-point values, or 64-bit BCD values is held in a FPR using all 64 bits. Data of 64 bits may be loaded from storage via any of the *Load Floating-Point Double* instructions and stored via any of the *Store Floating-Point Double* instructions.

Data in DFP Extended format or 128-bit BCD values is held in an even-odd FPR pair using all 128 bits. Data of 128 bits must be loaded into the desired even-odd pair of floating-point registers using an appropriate sequence of the *Load Floating-Point Double* instructions and stored using an appropriate sequence of the *Store Floating-Point Double* instructions.

Data used as a source operand by any *Decimal Floating-Point* instruction that was produced, either directly or indirectly, by a *Load Floating-Point Single* instruction, a *Floating Round to Single-Precision* instruction,

or a binary floating-point single-precision arithmetic instruction is boundedly undefined.

When an even-odd FPR pair is used to hold a 128-bit operand, the even-numbered FPR is used to hold the leftmost doubleword of the operand and the next higher-numbered FPR is used to hold the rightmost doubleword. A DFP instruction designating an odd-numbered FPR for a 128-bit operand is an invalid instruction form.

Programming Note

The *Floating-Point Move* instructions can be used to move operands between FPRs.

The bit definitions for the FPSCR are as follows.

Bit(s) Description

0:28 Reserved

29:31 **DFP Rounding Control (DRN)**
See Section 5.5.2, “Rounding Mode Specification” on page 161.

000 Round to Nearest, Ties to Even

001 Round toward Zero

010 Round toward +Infinity

011 Round toward -Infinity

100 Round to Nearest, Ties away from 0

101 Round to Nearest, Ties toward 0

110 Round to away from Zero

111 Round to Prepare for Shorter Precision

Programming Note

FPSCR₂₈ is reserved for extension of the DRN field, therefore DRN may be set using the *mtfsfi* instruction to set the rounding mode.

32 **Floating-Point Exception Summary (FX)**
Every floating-point instruction, except *mtfsfi* and *mtfsf*, implicitly sets FPSCR_{FX} to 1 if that instruction causes any of the floating-point exception bits in the FPSCR to change from 0 to 1. *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, and *mtfsb1* can alter FPSCR_{FX} explicitly.

33 **Floating-Point Enabled Exception Summary (FEX)**

This bit is the OR of all the floating-point exception bits masked by their respective enable bits. *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, and *mtfsb1* cannot alter FPSCR_{FEX} explicitly.

34 **Floating-Point Invalid Operation Exception Summary (VX)**

This bit is the OR of all the Invalid Operation exception bits. *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, and *mtfsb1* cannot alter FPSCR_{VX} explicitly.

35 **Floating-Point Overflow Exception (OX)**
See Section 5.5.10.3, “Overflow Exception” on page 167.

36 **Floating-Point Underflow Exception (UX)**
See Section 5.5.10.4, “Underflow Exception” on page 168.

37 **Floating-Point Zero Divide Exception (ZX)**
See Section 5.5.10.2, “Zero Divide Exception” on page 167.

38 **Floating-Point Inexact Exception (XX)**
See Section 5.5.10.5, “Inexact Exception” on page 169.

FPSCR_{XX} is a sticky version of FPSCR_{FI} (see below). Thus the following rules completely describe how FPSCR_{XX} is set by a given instruction.

- If the instruction affects FPSCR_{FI}, the new value of FPSCR_{XX} is obtained by ORing the old value of FPSCR_{XX} with the new value of FPSCR_{FI}.
- If the instruction does not affect FPSCR_{FI}, the value of FPSCR_{XX} is unchanged.

39 **Floating-Point Invalid Operation Exception (SNaN) (VXSNAN)**
See Section 5.5.10.1, “Invalid Operation Exception” on page 166.

40 **Floating-Point Invalid Operation Exception ($\infty - \infty$) (VXISI)**
See Section 5.5.10.1.

41 **Floating-Point Invalid Operation Exception ($\infty \div \infty$) (VXIDI)**
See Section 5.5.10.1.

442 **Floating-Point Invalid Operation Exception ($0 \div 0$) (VXZDZ)**
See Section 5.5.10.1.

43 **Floating-Point Invalid Operation Exception ($\infty \times 0$) (VXIMZ)**
See Section 5.5.10.1.

44 **Floating-Point Invalid Operation Exception (Invalid Compare) (VXVC)**
See Section 5.5.10.1.

45 **Floating-Point Fraction Rounded (FR)**
The last *Arithmetic* or *Rounding and Conversion* instruction incremented the fraction during rounding. See Section 5.5.1, “Rounding” on page 160. This bit is not sticky.

46 **Floating-Point Fraction Inexact (FI)**
The last *Arithmetic* or *Rounding and Conversion* instruction either produced an inexact result during rounding or caused a disabled Overflow Exception. See Section 5.5.1. This bit is not sticky.

- See the definition of $FPSCR_{XX}$, above, regarding the relationship between $FPSCR_{FI}$ and $FPSCR_{XX}$.
- 47:51 **Floating-Point Result Flags (FPRF)**
This field is set as described below. For arithmetic, rounding, and conversion instructions, the field is set based on the result placed into the target register, except that if any portion of the result is undefined then the value placed into FPRF is undefined.
- 47 **Floating-Point Result Class Descriptor (C)**
Arithmetic, rounding, and conversion instructions may set this bit with the FPCC bits, to indicate the class of the result as shown in Figure 61 on page 156.
- 48:51 **Floating-Point Condition Code (FPCC)**
Floating-point *Compare* and *DFP Test* instructions set one of the FPCC bits to 1 and the other three FPCC bits to 0. Arithmetic, rounding, and conversion instructions may set the FPCC bits with the C bit, to indicate the class of the result as shown in Figure 61 on page 156. Note that in this case the high-order three bits of the FPCC retain their relational significance indicating that the value is less than, greater than, or equal to zero.
- 48 **Floating-Point Less Than or Negative (FL or <)**
- 49 **Floating-Point Greater Than or Positive (FG or >)**
- 50 **Floating-Point Equal or Zero (FE or =)**
- 51 **Floating-Point Unordered or NaN (FU or ?)**
- 52 Reserved
- 53 **Floating-Point Invalid Operation Exception (Software Request) (VXSOFT)**
This bit can be altered only by *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, or *mtfsb1*. See Section 5.5.10.1, “Invalid Operation Exception” on page 166.
- 54 Neither used nor changed by DFP.
- 57 **Floating-Point Overflow Exception Enable (OE)**
See Section 5.5.10.3, “Overflow Exception” on page 167.
- 58 **Floating-Point Underflow Exception Enable (UE)**
See Section 5.5.10.4, “Underflow Exception” on page 168.
- 59 **Floating-Point Zero Divide Exception Enable (ZE)**
See Section 5.5.10.2, “Zero Divide Exception” on page 167.
- 60 **Floating-Point Inexact Exception Enable (XE)**
See Section 5.5.10.5, “Inexact Exception” on page 169.
- 61 Reserved (not used by DFP)
- 62:63 **Binary Floating-Point Rounding Control (RN)**
See Section 5.5.1, “Rounding” on page 160.
- 00 Round to Nearest
01 Round toward Zero
10 Round toward +Infinity
11 Round toward -Infinity

Result Flags	Result Value Class
C < > = ?	
0 0 0 0 1	Signaling NaN (DFP only)
1 0 0 0 1	Quiet NaN
0 1 0 0 1	- Infinity
0 1 0 0 0	- Normal Number
1 1 0 0 0	- Subnormal Number
1 0 0 1 0	- Zero
0 0 0 1 0	+ Zero
1 0 1 0 0	+ Subnormal Number
0 0 1 0 0	+ Normal Number
0 0 1 0 1	+ Infinity

Figure 61. Floating-Point Result Flags

5.3 DFP Support for Non-DFP Data Types

In addition to the DFP data types, the DFP processor provides limited support for the following non-DFP data types: signed or unsigned binary fixed-point data, and signed or unsigned decimal data.

In unsigned binary fixed-point data, all bits are used to express the absolute value of the number. For signed binary fixed-point data, the leftmost bit represents the sign, which is followed by the numeric field. Positive numbers are represented in true binary notation with the sign bit set to zero. When the value is zero, all bits

Programming Note

Although the architecture does not provide a DFP square root instruction, if software simulates such an instruction, it should set bit 54 whenever the source operand of the square root function is invalid.

are zeros, including the sign bit. Negative numbers are represented in two's complement binary notation with a one in the sign-bit position.

For decimal data, each byte contains a pair of four-bit nibbles; each four-bit nibble contains a binary-coded-decimal (BCD) code. There are two kinds of BCD codes: digit code and sign code. For unsigned decimal data, all nibbles contain a digit code (D) as shown in Figure 62

D	D	D	D	...	D	D	D	D
---	---	---	---	-----	---	---	---	---

Figure 62. Format for Unsigned Decimal Data

For signed decimal data, the rightmost nibble contains a sign code (S) and all other nibbles contain a digit code as shown in Figure 63.

D	D	D	D	...	D	D	D	S
---	---	---	---	-----	---	---	---	---

Figure 63. Format for Signed Decimal Data

The decimal digits 0-9 have the binary encoding 0000-1001. The preferred plus-sign codes are 1100 and 1111. The preferred minus sign code is 1101. These are the sign codes generated for the results of the *Decode DPD To BCD* instruction. A selection is provided by this instruction to specify which of the two preferred plus sign codes is to be generated. Alternate sign codes are also recognized as valid in the sign position: 1010 and 1110 are alternate sign codes for plus, and 1011 is an alternate sign code for minus. Alternate sign codes are accepted for any source operand, but are not generated as a result by the instruction. When an invalid digit or sign code is detected by the *Encode BCD To DPD* instruction, an invalid-opera-

tion exception occurs. A summary of digit and sign codes are provided in Figure 64.

Binary Code	Recognized As	
	Digit	Sign
0000	0	Invalid
0001	1	Invalid
0010	2	Invalid
0011	3	Invalid
0100	4	Invalid
0101	5	Invalid
0110	6	Invalid
0111	7	Invalid
1000	8	Invalid
1001	9	Invalid
1010	Invalid	Plus
1011	Invalid	Minus
1100	Invalid	Plus (preferred; option 1)
1101	Invalid	Minus (preferred)
1110	Invalid	Plus
1111	Invalid	Plus (preferred; option 2)

Figure 64. Summary of BCD Digit and Sign Codes

5.4 DFP Number Representation

A DFP finite number consists of three components: a sign bit, a signed exponent, and a significand. The signed exponent is a signed binary integer. The *significand* consists of a number of decimal digits, which are to the left of the implied decimal point. The rightmost digit of the significand is called the *units* digit. The numerical value of a DFP finite number is represented as $(-1)^{sign} \times significand \times 10^{exponent}$ and the unit value of this number is (1×10^{exponent}) , which is called the *quantum*.

DFP finite numbers are not normalized. This allows leading zeros and trailing zeros to exist in the significand. This unnormalized DFP number representation allows some values to have redundant forms; each form represents the DFP number with a different combination of the significand value and the exponent value. For example, 1000000×10^5 and 10×10^{10} are two different forms of the same numerical value. A *form* of this number representation carries information about both the numerical value and the quantum of a DFP finite number.

The *significant digits* of a DFP finite number are the digits in the significand beginning with the leftmost non-zero digit and ending with the units digit.

5.4.1 DFP Data Format

DFP numbers and NaNs may be represented in FPRs in any of the three data formats: DFP Short, DFP Long, or DFP Extended. The contents of each data format represent encoded information. Special codes are assigned to NaNs and infinities. Different formats support different sizes in both significand and exponent. Arithmetic, compare, test, quantum-adjustment, and format instructions are provided for DFP Long and DFP Extended formats only.

The *sign* is encoded as a one bit binary value. *Significand* is encoded as an unsigned decimal integer in two distinct parts. The leftmost digit (LMD) of the *significand* is encoded as part of the *combination* field; the remaining digits of the *significand* are encoded in the *trailing significand* field. The *exponent* is contained in the *combination* field in two parts. However, prior to encoding, the *exponent* is converted to an unsigned binary value called the *biased exponent* by adding a *bias* value which is a constant for each format. The two leftmost bits of the *biased exponent* are encoded with the leftmost digit of the significand in the leftmost bits of the *combination* field. The rest of the biased exponent occupies the remaining portion of the *combination* field.

5.4.1.1 Fields Within the Data Format

The DFP data representation comprises three fields, as diagrammed below for each of the three formats:

Figure 65. DFP Short format

Figure 66. DFP Long format

Figure 67. DFP Extended format

The fields are defined as follows:

Sign bit (S)

The sign bit is in bit 0 of each format, and is zero for plus and one for minus.

Combination field (G)

As the name implies, this field provides a combination of the exponent and the left-most digit (LMD) of the significand, for finite numbers, or provides a special code

for denoting the value as either a Not-a-Number or an Infinity.

The first 5 bits of the combination field contain the encoding of NaN or infinity, or the two leftmost bits of the biased exponent and the leftmost digit (LMD) of the significand. The following tables show the encoding:

G _{0:4}	Description
11111	NaN
11110	Infinity
All others	Finite Number (see Figure 69)

Figure 68. Encoding of the G field for Special Symbols

LMD	Leftmost 2-bits of biased exponent		
	00	01	10
0	00000	01000	10000
1	00001	01001	10001
2	00010	01010	10010
3	00011	01011	10011
4	00100	01100	10100
5	00101	01101	10101
6	00110	01110	10110
7	00111	01111	10111
8	11000	11010	11100
9	11001	11011	11101

Figure 69. Encoding of bits 0:4 of the G field for Finite Numbers

For DFP finite numbers, the rightmost N-5 bits of the N-bit combination field contain the remaining bits of the *biased exponent*. For NaNs, bit 5 of the combination field is used to distinguish a Quiet NaN from a Signaling NaN; the remaining bits in a source operand are ignored and they are set to zeros in a target operand by most operations. For infinities, the rightmost N-5 bits of the N-bit combination field of a source operand are ignored and they are set to zeros in a target operand by most operations.

Trailing Significand field (T)

For DFP finite numbers, this field contains the remaining *significand* digits. For NaNs, this field may be used to contain diagnostic information. For infinities, contents in this field of a source operand are ignored and they are set to zeros in a target operand by most operations. The trailing significand field is a multiple of 10-bit blocks. The multiple depends on the format. Each 10-bit block is called a deplet and represents three decimal digits, using the Densely Packed Decimal (DPD) encoding defined in Appendix B.

5.4.1.2 Summary of DFP Data Formats

The properties of the three DFP formats are summarized in the following table:

	Format		
	DFP Short	DFP Long	DFP Extended
Widths (bits):			
Format	32	64	128
Sign (S)	1	1	1
Combination (G)	11	13	17
Trailing Significand (T)	20	50	110
Exponent:			
Maximum biased	191	767	12,287
Maximum (X_{\max})	90	369	6111
Minimum (X_{\min})	-101	-398	-6176
Bias	101	398	6176
Precision (p) (digits)	7	16	34
Magnitude:			
Maximum normal number (N_{\max})	$(10^7 - 1) \times 10^{90}$	$(10^{16} - 1) \times 10^{369}$	$(10^{34} - 1) \times 10^{6111}$
Minimum normal number (N_{\min})	1×10^{-95}	1×10^{-383}	1×10^{-6143}
Minimum subnormal number (D_{\min})	1×10^{-101}	1×10^{-398}	1×10^{-6176}

Figure 70. Summary of DFP Formats

5.4.1.3 Preferred DPD Encoding

Execution of DFP instructions decodes source operands from DFP data formats to an internal format for processing, and encodes the operation result before the final result is returned as the target operand.

As part of the decoding process, declets in the trailing significand field of source operands are decoded to their corresponding BCD digit codes using the DPD-to-BCD decoding algorithm. As part of the encoding process, BCD digit codes to be stored into the trailing significand field of the target operand are encoded into declets using the BCD-to-DPD encoding algorithm. Both the decoding and encoding algorithms are defined in Appendix B.

As explained in Appendix B, there are eight 3-digit decimal values that have redundant DPD codes and one preferred DPD code. All redundant DPD codes are recognized in source operands for the associated 3-digit decimal number. DFP operations will always generate the preferred DPD codes for the trailing significand field of the target operand.

5.4.2 Classes of DFP Data

There are six classes of DFP data, which include numerical and nonnumeric entities. The numerical entities include zero, subnormal number, normal number, and infinity data classes. The nonnumeric entities include quiet and signaling NaNs data classes. The value of a DFP finite number, including zero, subnormal number, and normal number, is a quantization of the real number based on the data format. The *Test Data Class* instruction may be used to determine the class of a DFP operand. In general, an operation that returns a DFP result sets the $FPSCR_{FPRF}$ field to indicate the data class of the result.

The following tables show the value ranges for finite-number data classes, and the codes for NaNs and infinities.

Data Class	Sign	Magnitude
Zero	±	0*
Subnormal	±	$D_{\min} \leq X < N_{\min}$
Normal	±	$N_{\min} \leq Y \leq N_{\max}$
* The significand is zero and the exponent is any representable value		

Figure 71. Value Ranges for Finite Number Data Classes

Data Class	S	G	T
+Infinity	0	11110xxx . . . xxx	xxx . . . xxx
-Infinity	1	11110xxx . . . xxx	xxx . . . xxx
Quiet NaN	x	111110xx . . . xxx	xxx . . . xxx
Signaling NaN	x	111111xx . . . xxx	xxx . . . xxx
x	Don't care		

Figure 72. Encoding of NaN and Infinity Data Classes

Zeros

Zeros have a zero significand and any representable value in the exponent. A +0 is distinct from -0, and zeros with different exponents are distinct, except that comparison treats them as equal.

Subnormal Numbers

Subnormal numbers have values that are smaller than N_{\min} and greater than zero in magnitude.

Normal Numbers

Normal numbers are nonzero finite numbers whose magnitude is between N_{\min} and N_{\max} inclusively.

Infinities

Infinities are represented by 0b11110 in the leftmost 5 bits of the combination field. When an operation is defined to generate an infinity as the result, a default infinity is sometimes supplied. A default infinity has all remaining bits in the combination field and trailing significand field set to zeros.

When infinities are used as source operands, only the leftmost 5 bits of the combination field are interpreted (i.e., 0b11110 indicates the value is an infinity). The trailing significand field of infinities is usually ignored. For generated infinities, the leftmost 5 bits of the combination field are set to 0b11110 and all remaining combination bits are set to zero.

Infinities can participate in most arithmetic operations and give a consistent result. In comparisons, any +Infinity compares greater than any finite number, and any -Infinity compares less than any finite number. All +Infinity are compared equal and all -Infinity are compared equal.

Signaling and Quiet NaNs

There are two types of Not-a-Numbers (NaNs), Signaling (SNaN) and Quiet (QNaN).

0b111110 in the leftmost 6 bits of the combination field indicates a Quiet NaN, whereas 0b111111 indicates a Signaling NaN.

A special QNaN is sometimes supplied as the *default QNaN* for a disabled invalid-operation exception; it has a plus sign, the leftmost 6 bits of the combination field set to 0b111110 and remaining bits in the combination field and the trailing significand field set to zero.

Normally, source QNaNs are *propagated* during operations so that they will remain visible at the end. When a QNaN is propagated, the sign is preserved, the decimal value of the trailing significand field is preserved but reencoded using the preferred DPD codes, and the contents in the rightmost N-6 bits of the combination field set to zero, where N is the width of the combination field for the format.

A source SNaN generally causes an invalid-operation exception. If the exception is disabled, the SNaN is converted to the corresponding QNaN and propagated. The primary encoding difference between an SNaN and a QNaN is that bit 5 of an SNaN is 1 and bit 5 of a QNaN is 0. When an SNaN is propagated as a QNaN, bit 5 is set to 0, and, just as with QNaN propagation, the sign is preserved, the decimal value of the trailing significand field is preserved but reencoded using the preferred DPD codes, and the contents in the rightmost N-6 bits of the combination field set to zero, where N is the width of the combination field for the format. For some format-conversion instructions, a source SNaN does not cause an invalid-operation exception, and an SNaN is returned as the target operand.

For instructions with two source NaNs and a NaN is to be propagated as the result, do the following.

- If there is a QNaN in FRA and an SNaN in FRB, the SNaN in FRB is propagated.
- Otherwise, propagate the NaN is FRA.

5.5 DFP Execution Model

DFP operations are performed as if they first produce an intermediate result correct to infinite precision and with unbounded range. The intermediate result is then rounded to the destination's precision according to one of the eight DFP rounding modes. If the rounded result has only one form, it is delivered as the final result; if the rounded result has redundant forms, then an *ideal exponent* is used to select the form of the final result. The ideal exponent determines the form, not the value, of the final result. (See Section 5.5.3 "Formation of Final Result" on page 162.)

5.5.1 Rounding

Rounding takes a number regarded as infinitely precise and, if necessary, modifies it to fit the destination's precision. The destination's precision of an operation defines the set of permissible resultant values. For

most operations, the destination's precision is the target-format precision and the permissible resultant values are those values representable in the target format. For some special operations, the destination precision is constrained by both the target format and some additional restrictions, and the permissible resultant values are a subset of the values representable in the target format.

Rounding sets FPSCR bits FR and FI. When an inexact exception occurs, FI is set to one; otherwise, FI is set to zero. When an inexact exception occurs and if the rounded result is greater in magnitude than the intermediate result, then FR is set to one; otherwise, FR is set to zero. The exception is the *Round to FP Integer Without Inexact* instruction, which always sets FR and FI to zero. Rounding may cause an overflow exception or underflow exception; it may also cause an inexact exception.

Refer to Figure 73 below for rounding. Let Z be the intermediate result of a DFP operation. Z may or may not fit in the destination's precision. If Z is exactly one of the permissible representable resultant values, then the final result in all rounding modes is Z. Otherwise, either Z1 or Z2 is chosen to approximate the result, where Z1 and Z2 are the next larger and smaller permissible resultant values, respectively.

Figure 73. Rounding

Round to Nearest, Ties to Even

Choose the value that is closer to Z (Z1 or Z2). In case of a tie, choose the one whose units digit would have been even in the form with the largest common quantum of the two permissible resultant values. However, an infinitely precise result with magnitude at least $(N_{\max} + 0.5Q(N_{\max}))$ is rounded to infinity with no change in sign; where $Q(N_{\max})$ is the quantum of N_{\max} .

Round toward 0

Choose the smaller in magnitude (Z1 or Z2).

Round toward $+\infty$

Choose Z1.

Round toward $-\infty$

Choose Z2.

Round to Nearest, Ties away from 0

Choose the value that is closer to Z (Z1 or Z2). In case

of a tie, choose the larger in magnitude (Z1 or Z2). However, an infinitely precise result with magnitude at least $(N_{\max} + 0.5Q(N_{\max}))$ is rounded to infinity with no change in sign; where $Q(N_{\max})$ is the quantum of N_{\max} .

Round to Nearest, Ties toward 0

Choose the value that is closer to Z (Z1 or Z2). In case of a tie, choose the smaller in magnitude (Z1 or Z2). However, an infinitely precise result with magnitude greater than $(N_{\max} + 0.5Q(N_{\max}))$ is rounded to infinity with no change in sign; where $Q(N_{\max})$ is the quantum of N_{\max} .

Round away from 0

Choose the larger in magnitude (Z1 or Z2).

Round to prepare for shorter precision

Choose the smaller in magnitude (Z1 or Z2). If the selected value is inexact and the units digit of the selected value is either 0 or 5, then the digit is incremented by one and the incremented result is delivered. In all other cases, the selected value is delivered. When a value has redundant forms, the units digit is determined by using the form that has the smallest exponent.

5.5.2 Rounding Mode Specification

Unless otherwise specified in the instruction definition, the rounding mode used by an operation is specified in the DFP rounding control (DRN) field of the FPSCR. The eight DFP rounding modes are encoded in the DRN field as specified in the table below.

DRN	Rounding Mode
000	Round to Nearest, Ties to Even
001	Round toward 0
010	Round toward $+\infty$
011	Round toward $-\infty$
100	Round to Nearest, Ties away from 0
101	Round to Nearest, Ties toward 0
110	Round away from 0
111	Round to Prepare for Shorter Precision

Figure 74. Encoding of DFP Rounding-Mode Control (DRN)

For the quantum-adjustment, a 2-bit immediate field, called RMC (*Rounding Mode Control*), in the instruction specifies the rounding mode used. The RMC field may contain a primary encoding or a secondary encoding. For *Quantize*, *Quantize Immediate*, and *Reround*, the RMC field contains the primary encoding. For *Round to FP Integer* the field contains either encoding, depending on the setting of a RMC-encoding-selection

bit. The following tables define the primary encoding and the secondary encoding.

Primary RMC	Rounding Mode
00	Round to nearest, ties to even
01	Round toward 0
10	Round to nearest, ties away from 0
11	Round according to $FPSCR_{DRN}$

Figure 75. Primary Encoding of Rounding-Mode Control

Secondary RMC	Rounding Mode
00	Round to $+\infty$
01	Round to $-\infty$
10	Round away from 0
11	Round to nearest, ties toward 0

Figure 76. Secondary Encoding of Rounding-Mode Control

5.5.3 Formation of Final Result

An ideal exponent is defined for each DFP instruction that returns a DFP data operand.

5.5.3.1 Use of Ideal Exponent

For all DFP operations,

- if the rounded intermediate result has only one form, then that form is delivered as the final result.
- if the rounded intermediate result has redundant forms and is exact, then the form with the exponent closest to the ideal exponent is delivered.
- if the rounded intermediate result has redundant forms and is inexact, then the form with the smallest exponent is delivered.

The following table specifies the ideal exponent for each instruction.

Operations	Ideal Exponent
Add	$\min(E(FRA), E(FRB))$
Subtract	$\min(E(FRA), E(FRB))$
Multiply	$E(FRA) + E(FRB)$
Divide	$E(FRA) - E(FRB)$
Quantize-Immediate	See Instruction Description
Quantize	$E(FRA)$
Reround	See Instruction Description
Round to FP Integer	$\max(0, E(FRA))$
Convert to DFP Long	$E(FRA)$
Convert to DFP Extended	$E(FRA)$
Round to DFP Short	$E(FRA)$
Round to DFP Long	$E(FRA)$
Convert from Fixed	0
Encode BCD to DPD	0
Insert Biased Exponent	$E(FRA)$

Notes:
 $E(x)$ - exponent of the DFP operand in register x.

Figure 77. Summary of Ideal Exponents

5.5.4 Arithmetic Operations

Four arithmetic operations are provided: Add, Subtract, Multiply, and Divide.

5.5.4.1 Sign of Arithmetic Result

The following rules govern the sign of an arithmetic operation when the operation does not yield an exception. They apply even when the operands or results are zeros or infinities.

- The sign of the result of an add operation is the sign of the source operand having the larger absolute value. If both source operands have the same sign, the sign of the result of an add operation is the same as the sign of the source operands. When the sum of two operands with opposite signs is exactly zero, the sign of the result is positive in all rounding modes except Round toward $-\infty$, in which case the sign is negative.
- The sign of the result of the subtract operation $x - y$ is the same as the sign of the result of the add operation $x + (-y)$.
- The sign of the result of a multiply or divide operation is the exclusive-OR of the signs of the source operands.

5.5.5 Compare Operations

Two sets of instructions are provided for comparing numerical values: *Compare Ordered* and *Compare Unordered*. In the absence of NaNs, these instructions work the same. These instructions work differently when either of the followings is true:

1. At least one source operand of the instruction is an SNaN and the invalid-operation exception is disabled.
2. When there is no SNaN in any source operand, at least one source operand of the instruction is a QNaN

In case 1, *Compare Unordered* recognizes an invalid-operation exception and sets the FPSCR_{VXS-NAN} flag, but *Compare Ordered* recognizes the exception and sets both the FPSCR_{VXSNaN} and FPSCR_{VXVC} flags. In case 2, *Compare Unordered* does not recognize an exception, but *Compare Ordered* recognizes an invalid-operation exception and sets the FPSCR_{VXVC} flag.

For finite numbers, comparisons are performed on values, that is, all redundant forms of a DFP number are treated equal.

Comparisons are always exact and cannot cause an inexact exception.

Comparison ignores the sign of zero, that is, +0 equals -0.

Infinities with like sign compare equal, that is, $+\infty$ equals $+\infty$, and $-\infty$ equals $-\infty$.

A NaN compares as unordered with any other operand, whether a finite number, an infinity, or another NaN, including itself.

Execution of a compare instruction always completes, regardless of whether any DFP exception occurs or not, and whether the exception is enabled or not.

5.5.6 Test Operations

Four kinds of test operations are provided: *Test Data Class*, *Test Data Group*, *Test Exponent*, and *Test Significance*.

The *Test Data Class* instruction examines the contents of a source operand and determines if the operand is one of the specified data classes. The test result and the sign of the source operand are indicated in the FPSCR_{FPCC} field and CR field BF.

The *Test Data Group* instruction examines the contents of a source operand and determines if the operand is one of the specified data groups. The test result and the sign of the source operand are indicated in the FPSCR_{FPCC} field and CR field BF.

The *Test Exponent* instruction compares the exponent of the two source operands. The test operation ignores

the sign and significand of operands. Infinities compare equal, and NaNs compare equal. The test result is indicated in the FPSCR_{FPCC} field and CR field BF.

The *Test Significance* instruction compares the number of significant digits of one source operand with the referenced number of significant digits in another source operand. The test result is indicated in the FPSCR_{FPCC} field and CR field BF.

Execution of a test instruction does not cause any DFP exception.

5.5.7 Quantum Adjustment Operations

Four kinds of quantum-adjustment operations are provided: *Quantize*, *Quantize Immediate*, *Reround*, and *Round To FP Integer*. Each of them has an immediate field which specifies whether the rounding mode in FPSCR or a different one is to be used.

The *Quantize* instruction is used to adjust a DFP number to the form that has the specified target exponent. The *Quantize Immediate* instruction is similar to the *Quantize* instruction, except that the target exponent is specified in a 5-bit immediate field as a signed binary integer and has a limited range.

The *Reround* instruction is used to simulate a DFP operation of a precision other than that of DFP Long or DFP Extended. For the *Reround* instruction to produce a result which accurately reflects that which would have resulted from a DFP operation of the desired precision d in the range {1: 33} inclusively, the following conditions must be met:

- The precision of the preceding DFP operation must be at least one digit larger than d .
- The rounding mode used by the preceding DFP operation must be *round-to-prepare-for-shorter-precision*.

The *Round To FP Integer* instruction is used to round a DFP number to an integer value of the same format. The target exponent is implicitly specified, and is greater than or equal to zero.

5.5.8 Conversion Operations

There are two kinds of conversion operations: data-format conversion and data-type conversion.

5.5.8.1 Data-Format Conversion

The instructions *Convert To DFP Long* and *Convert To DFP Extended* convert DFP operands to wider formats; the instructions *Round To DFP Short* and *Round To DFP Long* convert DFP operands to narrower formats.

When converting a finite number to a wider format, the result is exact. When converting a finite number to a

narrower format, the source operand is rounded to the target-format precision, which is specified by the instruction, not by the target register size.

When converting a finite number, the ideal exponent of the result is the source exponent.

Conversion of an infinity or NaN to a different format does not preserve the source combination field. Let N be the width of the target format's combination field.

- When the result is an infinity or a QNaN, the contents of the rightmost $N-5$ bits of the N -bit target combination field are set to zero.
- When the result is an SNaN, bit 5 of the target format's combination field is set to one and the rightmost $N-6$ bits of the N -bit target combination field are set to zero.

When converting a NaN to a wider format or when converting an infinity from DFP Short to DFP Long, digits in the source trailing significand field are reencoded using the preferred DPD codes with sufficient zeros appended on the left to form the target trailing significand field. When converting a NaN to a narrower format or when converting an infinity from DFP Long to DFP Short, the appropriate number of leftmost digits of the source trailing significand field are removed and the remaining digits of the field are reencoded using the preferred DPD codes to form the target trailing significand field.

When converting an infinity between DFP Long and DFP Extended, a default infinity with the same sign is produced.

When converting an SNaN between DFP Short and DFP Long, it is converted to an SNaN without causing an invalid-operation exception. When converting an SNaN between DFP Long and DFP Extended, the invalid-operation exception occurs; if the invalid-operation exception is disabled, the result is converted to the corresponding QNaN.

5.5.8.2 Data-Type Conversion

The instructions *Convert From Fixed* and *Convert To Fixed* are provided to convert a number between the DFP data type and the signed 64-bit binary-integer data type.

Conversion of a signed 64-bit binary integer to a DFP Extended number is always exact.

Conversion of a DFP number to a signed 64-bit binary integer results in an invalid-operation exception when the converted value does not fit into the target format, or when the source operand is an infinity or NaN. When the exception is disabled, the most positive integer is returned if the source operand is a positive number or $+\infty$, and the most negative integer is returned if the source operand is a negative number, $-\infty$, or NaN.

5.5.9 Format Operations

The format instructions are provided to facilitate composing or decomposing a DFP number, and consist of *Encode BCD To DPD*, *Decode DPD To BCD*, *Extract Biased Exponent*, *Insert Biased Exponent*, *Shift Significant Left Immediate*, and *Shift Significant Right Immediate*. A source operand of SNaN does not cause an invalid-operation exception, and an SNaN may be produced as the target operand.

5.5.10 DFP Exceptions

This architecture defines the following DFP exceptions:

- Invalid Operation Exception
 - SNaN
 - $\infty - \infty$
 - $\infty \div \infty$
 - $0 \div 0$
 - $\infty \times 0$
 - Invalid Compare
 - Invalid Conversion
- Zero Divide Exception
- Overflow Exception
- Underflow Exception
- Inexact Exception

These exceptions may occur during execution of a DFP instruction.

Each DFP exception, and each category of the Invalid Operation Exception, has an exception status bit in the FPSCR. In addition, each DFP exception has a corresponding enable bit in the FPSCR. The exception status bit indicates occurrence of the corresponding exception. If an exception occurs, the corresponding enable bit governs the result produced by the instruction and, in conjunction with the FE0 and FE1 bits (see the discussion of FE0 and FE1 below), whether and how the system floating-point enabled exception error handler is invoked. (In general, the enabling specified by the enable bit is of invoking the system error handler, not of permitting the exception to occur. The occurrence of an exception depends only on the instruction and its source operands, not on the setting of any control bits. The only deviation from this general rule is that the occurrence of an Underflow Exception may depend on the setting of the enable bit.)

A single instruction, other than *mtfsfi* or *mtfsf*, may set more than one exception bit only in the following cases:

- Inexact Exception may be set with Overflow Exception.
- Inexact Exception may be set with Underflow Exception.
- Invalid Operation Exception (SNaN) may be set with Invalid Operation Exception (Invalid Compare) for *Compare Ordered* instructions

- Invalid Operation Exception (SNaN) may be set with Invalid Operation Exception (Invalid Conversion) for *Convert To Fixed* instructions.

When an exception occurs the instruction execution may be completed or partially completed, depending on the exception and the operation.

For all instructions, except for the Compare and Test instructions, the following exceptions cause the instruction execution to be partially completed. That is, setting of CR field 1 (when Rc=1) and exception status flags is performed, but no result is stored into the target FPR or FPR pair. For Compare and Test instructions, instruction execution is always completed, regardless of whether any DFP exception occurs or not, and whether the exception is enabled or not.

- Enabled Invalid Operation
- Enabled Zero Divide

For the remaining kinds of exceptions, instruction execution is completed, a result, if specified by the instruction, is generated and stored into the target FPR or FPR pair, and appropriate status flags are set. The result may be a different value for the enabled and disabled conditions for some of these exceptions. The kinds of exceptions that deliver a result in target FPR are the following:

- Disabled Invalid Operation
- Disabled Zero Divide
- Disabled Overflow
- Disabled Underflow
- Disabled Inexact
- Enabled Overflow
- Enabled Underflow
- Enabled Inexact

Subsequent sections define each of the DFP exceptions and specify the action that is taken when they are detected.

The IEEE standard specifies the handling of exceptional conditions in terms of “traps” and “trap handlers”. In this architecture, a FPSCR exception enable bit of 1 causes generation of the result value specified in the IEEE standard for the “trap enabled” case: the expectation is that the exception will be detected by software, which will revise the result. A FPSCR exception enable bit of 0 causes generation of the “default result” value specified for the “trap disabled” (or “no trap occurs” or “trap is not implemented”) case: the expectation is that the exception will not be detected by software, which will simply use the default result. The result to be delivered in each case for each exception is described in the sections below.

The IEEE default behavior when an exception occurs is to generate a default value and not to notify software. In this architecture, if the IEEE default behavior when an exception occurs is desired for all exceptions, all FPSCR exception enable bits should be set to zero and Ignore Exceptions Mode (see below) should be used.

In this case the system floating-point enabled exception error handler is not invoked, even if DFP exceptions occur: software can inspect the FPSCR exception bits if necessary, to determine whether exceptions have occurred.

In this architecture, if software is to be notified that a given kind of exception has occurred, the corresponding FPSCR exception enable bit must be set to one and a mode other than Ignore Exceptions Mode must be used. In this case the system floating-point enabled exception error handler is invoked if an enabled DFP exception occurs. The system floating-point enabled exception error handler is also invoked if a *Move To FPSCR* instruction causes an exception bit and the corresponding enable bit both to be 1; the *Move To FPSCR* instruction is considered to cause the enabled exception.

The FE0 and FE1 bits control whether and how the system floating-point enabled exception error handler is invoked if an enabled DFP exception occurs. The location of these bits and the requirements for altering them are described in Book III, *Power AS Operating Environment Architecture*. (The system floating-point enabled exception error handler is never invoked because of a disabled DFP exception.) The effects of the four possible settings of these bits are as follows.

FE0	FE1	Description
0	0	Ignore Exceptions Mode DFP exceptions do not cause the system floating-point enabled exception error handler to be invoked.
0	1	Imprecise Nonrecoverable Mode The system floating-point enabled exception error handler is invoked at some point at or beyond the instruction that caused the enabled exception. It may not be possible to identify the excepting instruction or the data that caused the exception. Results produced by the excepting instruction may have been used by or may have affected subsequent instructions that are executed before the error handler is invoked.
1	0	Imprecise Recoverable Mode The system floating-point enabled exception error handler is invoked at some point at or beyond the instruction that caused the enabled exception. Sufficient information is provided to the error handler that it can identify the excepting instruction and the operands, and correct the result. No results produced by the excepting instruction have been used by or have affected subsequent instructions that are executed before the error handler is invoked.

FE0 FE1 Description**1 1 Precise Mode**

The system floating-point enabled exception error handler is invoked precisely at the instruction that caused the enabled exception.

In all cases, the question of whether a DFP result is stored, and what value is stored, is governed by the FPSCR exception enable bits, as described in subsequent sections, and is not affected by the value of the FE0 and FE1 bits.

In all cases in which the system floating-point enabled exception error handler is invoked, all instructions before the instruction at which the system floating-point enabled exception error handler is invoked have completed, and no instruction after the instruction at which the system floating-point enabled exception error handler is invoked has begun execution. (Recall that, for the two Imprecise modes, the instruction at which the system floating-point enabled exception error handler is invoked need not be the instruction that caused the exception.) The instruction at which the system floating-point enabled exception error handler is invoked has not been executed unless it is the excepting instruction, in which case it has been executed if the exception is not among those listed on page 164 as suppressed.

Programming Note

In the ignore and both imprecise modes, a *Floating-Point Status and Control Register* instruction can be used to force any exceptions, due to instructions initiated before the *Floating-Point Status and Control Register* instruction, to be recorded in the FPSCR. (This forcing is superfluous for Precise Mode.)

In either of the Imprecise modes, a *Floating-Point Status and Control Register* instruction can be used to force any invocations of the system floating-point enabled exception error handler, due to instructions initiated before the *Floating-Point Status and Control Register* instruction, to occur. (This forcing has no effect in Ignore Exceptions Mode, and is superfluous for Precise Mode.)

In order to obtain the best performance across the widest range of implementations, the programmer should obey the following guidelines.

- If the IEEE default results are acceptable to the application, Ignore Exceptions Mode should be used with all FPSCR exception enable bits set to zero.
- If the IEEE default results are not acceptable to the application, Imprecise Nonrecoverable Mode should be used, or Imprecise Recoverable Mode if recoverability is needed, with FPSCR exception

enable bits set to one for those exceptions for which the system floating-point enabled exception error handler is to be invoked.

- Ignore Exceptions Mode should not, in general, be used when any FPSCR exception enable bits are set to one.
- Precise Mode may degrade performance in some implementations, perhaps substantially, and therefore should be used only for debugging and other specialized applications.

5.5.10.1 Invalid Operation Exception**Definition**

An Invalid Operation Exception occurs when an operand is invalid for the specified DFP operation. The invalid DFP operations are:

- Any DFP operation on a signaling NaN (SNaN), except for *Test*, *Round To DFP Short*, *Convert To DFP Long*, *Decode DPD To BCD*, *Extract Biased Exponent*, *Insert Biased Exponent*, *Shift Significand Left Immediate*, and *Shift Significand Right Immediate*
- For add or subtract operations, magnitude subtraction of infinities $(+\infty) + (-\infty)$
- Division of infinity by infinity $(\infty \div \infty)$
- Division of zero by zero $(0 \div 0)$
- Multiplication of infinity by zero $(\infty \times 0)$
- Ordered comparison involving a NaN (Invalid Compare)
- The *Quantize* operation detects that the significand associated with the specified target exponent would have more significant digits than the target-format precision
- For the *Quantize* operation, when one source operand specifies an infinity and the other specifies a finite number
- The *Reround* operation detects that the target exponent associated with the specified target significance would be greater than X_{\max}
- The *Encode BCD To DPD* operation detects an invalid BCD digit or sign code
- The *Convert To Fixed* operation involving a number too large in magnitude to be represented in the target format, or involving a NaN.

Programming Note

In addition, an Invalid Operation Exception occurs if software explicitly requests this by executing an *mtfsfi*, *mtfsf*, or *mtfsb1* instruction that sets $FPSCR_{VXSOFT}$ to 1 (Software Request). The purpose of $FPSCR_{VXSOFT}$ is to allow software to cause an Invalid Operation Exception for a condition that is not necessarily associated with the execution of a DFP instruction. For example, it might be set by a program that computes a square root, if the source operand is negative.

Action

The action to be taken depends on the setting of the Invalid Operation Exception Enable bit of the FPSCR.

When Invalid Operation Exception is enabled ($FPSCR_{VE}=1$) and Invalid Operation occurs, the following actions are taken:

- One or two Invalid Operation Exceptions are set:

$FPSCR_{VXSNAN}$	(if SNaN)
$FPSCR_{VXISI}$	(if $\infty - \infty$)
$FPSCR_{VXIDI}$	(if $\infty \div \infty$)
$FPSCR_{VXZDZ}$	(if $0 \div 0$)
$FPSCR_{VXIMZ}$	(if $\infty \times 0$)
$FPSCR_{VXVC}$	(if invalid comp)
$FPSCR_{VXCVI}$	(if invalid conversion)
- If the operation is an arithmetic, quantum-adjustment, conversion, or format, the target FPR is unchanged, $FPSCR_{FR FI}$ are set to zero, and $FPSCR_{FPRF}$ is unchanged.
- If the operation is a compare, $FPSCR_{FR FI C}$ are unchanged, and $FPSCR_{FPCC}$ is set to reflect unordered.

When Invalid Operation Exception is disabled ($FPSCR_{VE}=0$) and Invalid Operation occurs, the following actions are taken:

- One or two Invalid Operation Exceptions are set:

$FPSCR_{VXSNAN}$	(if SNaN)
$FPSCR_{VXISI}$	(if $\infty - \infty$)
$FPSCR_{VXIDI}$	(if $\infty \div \infty$)
$FPSCR_{VXZDZ}$	(if $0 \div 0$)
$FPSCR_{VXIMZ}$	(if $\infty \times 0$)
$FPSCR_{VXVC}$	(if invalid comp)
$FPSCR_{VXCVI}$	(if invalid conversion)
- If the operation is an arithmetic, quantum-adjustment, *Round to DFP Long*, *Convert to DFP Extended*, or format the target FPR is set to a Quiet NaN, $FPSCR_{FR FI}$ are set to zero, $FPSCR_{FPRF}$ is set to indicate the class of the result (Quiet NaN)
- If the operation is a *Convert To Fixed* the target FPR is set as follows:

FRT	is set to the most positive 64-bit binary integer if the operand in FRB is a positive or
-------	--

$+\infty$, and to the most negative 64-bit binary integer if the operand in FRB is a negative number, $-\infty$, or NaN.

$FPSCR_{FR FI}$ are set to zero

$FPSCR_{FPRF}$ is unchanged

- If the operation is a compare, $FPSCR_{FR FI C}$ are unchanged, $FPSCR_{FPCC}$ is set to reflect unordered

5.5.10.2 Zero Divide Exception**Definition**

A Zero Divide Exception occurs when a Divide instruction is executed with a zero divisor value and a finite nonzero dividend value.

Action

The action to be taken depends on the setting of the Zero Divide Exception Enable bit of the FPSCR.

When Zero Divide Exception is enabled ($FPSCR_{ZE}=1$) and Zero Divide occurs, the following actions are taken:

- Zero Divide Exception is set
 $FPSCR_{ZX} \leftarrow 1$
- The target FPR is unchanged
- $FPSCR_{FR FI}$ are set to zero
- $FPSCR_{FPRF}$ is unchanged

When Zero Divide Exception is disabled ($FPSCR_{ZE}=0$) and Zero Divide occurs, the following actions are taken:

- Zero Divide Exception is set
 $FPSCR_{ZX} \leftarrow 1$
- The target FPR is set to $\pm\infty$, where the sign is determined by the XOR of the signs of the operands
- $FPSCR_{FR FI}$ are set to zero
- $FPSCR_{FPRF}$ is set to indicate the class and sign of the result ($\pm\infty$)

5.5.10.3 Overflow Exception**Definition**

An overflow exception occurs whenever the target format's largest finite number is exceeded in magnitude by what would have been the rounded result if the exponent range were unbounded.

Action

Except for *Reround*, the following describes the handling of the IEEE overflow exception condition. The *Reround* operation does not recognize an overflow exception condition.

The action to be taken depends on the setting of the Overflow Exception Enable bit of the FPSCR.

When Overflow Exception is enabled ($FPSCR_{OE}=1$) and overflow occurs, the following actions are taken:

1. Overflow Exception is set
 $FPSCR_{OX} \leftarrow 1$
2. The infinitely precise result is divided by 10^α . That is, the exponent adjustment α is subtracted from the exponent. This is called the *wrapped result*. The exponent adjustment for all operations, except for *Round To DFP Short* and *Round To DFP Long*, is 576 for DFP Long and 9216 for DFP Extended. For *Round To DFP Short* and *Round To DFP Long*, the exponent adjustment is 192 for the source format of DFP Long and 3072 for the source format of DFP Extended.
3. The wrapped result is rounded to the target-format precision. This is called the *wrapped rounded result*.
4. If the wrapped rounded result has only one form, it is the delivered result. If the wrapped rounded result has redundant forms and is exact, the result of the form that has the exponent closest to the wrapped ideal exponent is returned. If the wrapped rounded result has redundant forms and is inexact, the result of the form that has the smallest exponent is returned. The wrapped ideal exponent is the result of subtracting the exponent adjustment from the ideal exponent.
5. $FPSCR_{FPRF}$ is set to indicate the class and sign of the result (\pm Normal Number)

When Overflow Exception is disabled ($FPSCR_{OE}=0$) and overflow occurs, the following actions are taken:

1. Overflow Exception is set
 $FPSCR_{OX} \leftarrow 1$
2. Inexact Exception is set
 $FPSCR_{XX} \leftarrow 1$
3. The result is determined by the rounding mode and the sign of the intermediate result as follows.

Rounding Mode	Sign of intermediate result	
	Plus	Minus
Round to Nearest, Ties to Even	$+\infty$	$-\infty$
Round toward 0	$+N_{max}$	$-N_{max}$
Round toward $+\infty$	$+\infty$	$-N_{max}$
Round toward $-\infty$	$+N_{max}$	$-\infty$
Round to Nearest, Ties away from 0	$+\infty$	$-\infty$
Round to Nearest, Ties toward 0	$+\infty$	$-\infty$
Round away from 0	$+\infty$	$-\infty$
Round to prepare for shorter precision	$+N_{max}$	$-N_{max}$

Figure 78. Overflow Results When Exception Is Disabled

4. The result is placed into the target FPR
5. $FPSCR_{FR}$ is set to one if the returned result is $\pm \infty$, and is set to zero if the returned result is $\pm N_{max}$
6. $FPSCR_{FI}$ is set to one
7. $FPSCR_{FPRF}$ is set to indicate the class and sign of the result ($\pm \infty$ or \pm Normal number)

5.5.10.4 Underflow Exception

Definition

Except for *Reround*, the following describes the handling of the IEEE underflow exception condition. The *Reround* operation does not recognize an underflow exception condition.

The Underflow Exception is defined differently for the enabled and disabled states. However, a tininess condition is recognized in both states when a result computed as though both the precision and exponent range were unbounded would be nonzero and less than the target format's smallest normal number, N_{min} , in magnitude.

Unless otherwise defined in the instruction description, an underflow exception occurs as follows:

- Enabled:
When the tininess condition is recognized.
- Disabled:
When the tininess condition is recognized and when the delivered result value differs from what would have been computed were both the precision and the exponent range unbounded.

Action

The action to be taken depends on the setting of the Underflow Exception Enable bit of the FPSCR.

When Underflow Exception is enabled ($FPSCR_{UE}=1$) and underflow occurs, the following actions are taken:

1. Underflow Exception is set
 $FPSCR_{UX} \leftarrow 1$
2. The infinitely precise result is multiplied by 10^α . That is, the exponent adjustment α is added to the exponent. This is called the *wrapped result*. The exponent adjustment for all operations, except for *Round To DFP Short* and *Round To DFP Long*, is 576 for DFP Long and 9216 for DFP Extended. For *Round To DFP Short* and *Round To DFP Long*, the exponent adjustment is 192 for the source format of DFP Long and 3072 for the source format of DFP Extended.
3. The wrapped result is rounded to the target-format precision. This is called the *wrapped rounded result*.
4. If the wrapped rounded result has only one form, it is the delivered result. If the wrapped rounded result has redundant forms and is exact, the result of the form that has the exponent closest to the

wrapped ideal exponent is returned. If the wrapped rounded result has redundant forms and is inexact, the result of the form that has the smallest exponent is returned. The wrapped ideal exponent is the result of adding the exponent adjustment to the ideal exponent.

5. $FPSCR_{FPRF}$ is set to indicate the class and sign of the result (\pm Normal number)

When Underflow Exception is disabled ($FPSCR_{UE}=0$) and underflow occurs, the following actions are taken:

1. Underflow Exception is set
 $FPSCR_{UX} \leftarrow 1$
2. The infinitely precise result is rounded to the target-format precision.
3. The rounded result is returned. If this result has redundant forms, the result of the form that is closest to the ideal exponent is returned.
4. $FPSCR_{FPRF}$ is set to indicate the class and sign of the result (\pm Normal number, \pm Subnormal Number, or \pm Zero)

5.5.10.5 Inexact Exception

Definition

Except for *Round to FP Integer Without Inexact*, the following describes the handling of the IEEE inexact exception condition. The *Round to FP Integer Without Inexact* does not recognize an inexact exception condition.

An Inexact Exception occurs when either of two conditions occur during rounding:

1. The delivered result differs from what would have been computed were both the precision and exponent range unbounded.
2. The rounded result overflows and Overflow Exception is disabled.

Action

The action to be taken does not depend on the setting of the Inexact Exception Enable bit of the FPSCR.

When Inexact Exception occurs, the following actions are taken:

1. Inexact Exception is set
 $FPSCR_{XX} \leftarrow 1$
2. The rounded or overflowed result is placed into the target FPR
3. $FPSCR_{FPRF}$ is set to indicate the class and sign of the result

Programming Note

In some implementations, enabling Inexact Exceptions may degrade performance more than does enabling other types of floating-point exception.

5.5.11 Summary of Normal Rounding And Range Actions

Figure 79 and Figure 80 summarize rounding and range actions, with the following exceptions:

- The *Reround* operation recognizes neither an underflow nor an overflow exception.
- The *Round to FP Integer Without Inexact* operation does not recognize the inexact operation exception.

Range of v	Case	Result (r) when Rounding Mode Is							
		RNE	RNTZ	RNAZ	RAFZ	RTMI	RFSP	RTPI	RTZ
$v < -N_{max}$, $q < -N_{max}$	Overflow	$-\infty^1$	$-\infty^1$	$-\infty^1$	$-\infty^1$	$-\infty^1$	$-N_{max}$	$-N_{max}$	$-N_{max}$

Explanation:

- This situation cannot occur.
- 1 The normal result r is considered to have been incremented.
- * The rounded value, in the extreme case, may be N_{min} . In this case, the exception conditions are underflow, inexact, and incremented.
- b The value derived when the precise result v is rounded to the destination's precision, including both bounded precision and bounded exponent range.
- q The value derived when the precise result v is rounded to the destination's precision, but assuming an unbounded exponent range.
- r This is the returned value when neither overflow nor underflow is enabled.
- v Precise result before rounding, assuming unbounded precision and an unbounded exponent range. For data-format conversion operations, v is the source value.
- D_{min} Smallest (in magnitude) representable subnormal number in the target format.
- EZD The result r of the exact-zero-difference case applies only to ADD and SUBTRACT with both source operands having opposite signs. (For ADD and SUBTRACT, when both source operands have the same sign, the sign of the zero result is the same sign as the sign of the source operands.)
- N_{max} Largest (in magnitude) representable finite number in the target format.
- N_{min} Smallest (in magnitude) representable normalized number in the target format.
- RAFZ Round away from 0.
- RFSP Round to Prepare for Shorter Precision.
- RNAZ Round to Nearest, Ties away from 0.
- RNE Round to Nearest, Ties to even.
- RNTZ Round to Nearest, Ties toward 0.
- RTPI Round toward $+\infty$.
- RTMI Round toward $-\infty$.
- RTZ Round toward 0.

Tiny	Yes	—	Yes	—	—	Yes	Yes	Tw(q•β), UX← 1, FI← 1, FR← 1, XX ← 1, TU

Explanation:

- The results do not depend on this condition.
- ¹ This condition is true by virtue of the state of some condition to the left of this column.
- * Rounding sets only the FI and FR status flags. Setting of the OX, XX, or UX flag is part of the exception actions. They are listed here for reference.
- β Wrap adjust, which depends on the type of operation and operand format. For all operations except *Round to DFP Short* and *Round to DFP Long*, the wrap adjust depends on the target format: $\beta = 10^\alpha$, where α is 576 for DFP Long, and 9216 for DFP Extended. For *Round to DFP Short* and *Round to DFP Long*, the wrap adjust depends on the source format: $\beta = 10^\kappa$ where κ is 192 for DFP Long and 3072 for DFP Extended.
- q The value derived when the precise result v is rounded to destination's precision, but assuming an unbounded exponent range.
- r The result as defined in Part 1 of this figure.
- v Precise result before rounding, assuming unbounded precision and unbounded exponent range.
- FI Floating-Point-Fraction-Inexact status flag, FPSCR_{FI}. This status flag is non-sticky.
- FR Floating-Point-Fraction-Rounded status flag, FPSCR_{FR}.
- OX Floating-Point Overflow Exception status flag, FPSCR_{OX}.
- TO The system floating-point enabled exception error handler is invoked for the overflow exception if the FE0 and FE1 bits in the machine-state register are set to any mode other than the ignore-exception mode.
- TU The system floating-point enabled exception error handler is invoked for the underflow exception if the FE0 and FE1 bits in the machine-state register are set to any mode other than the ignore-exception mode.
- TX The system floating-point enabled exception error handler is invoked for the inexact exception if the FE0 and FE1 bits in the machine-state register are set to any mode other than the ignore-exception mode.
- T(x) The value x is placed at the target operand location.
- Tw(x) The wrapped rounded result x is placed at the target operand location. For all operations except data format conversions, the wrapped rounded result is in the same format and length as normal results at the target location. For data format conversions, the wrapped rounded result is in the same format and length as the source, but rounded to the target-format precision.
- UX Floating-Point-Underflow-Exception status flag, FPSCR_{UX}.
- XX Float-Point-Inexact-Exception Status flag, FPSCR_{XX}. The flag is a sticky version of FPSCR_{FI}. When FPSCR_{FI} is set to a new value, the new value of FPSCR_{XX} is set to the result of ORing the old value of FPSCR_{XX} with the new value of FPSCR_{FI}.

Figure 80. Rounding and Range Actions (Part 2)

5.6 DFP Instruction Descriptions

The following sections describe the DFP instructions. When a 128-bit operand is used, it is held in a FPR pair and the instruction mnemonic uses a letter “q” to mean the quad-precision operation. Note that in the following descriptions, FPXp denotes a FPR pair and must address an even-odd pair. If the FPXp field specifies an odd-numbered register, then the instruction form is invalid. The notation FPX[p] means either a FPR, FPX, or a FPR pair, FPXp.

For DFP instructions, if a DFP operand is returned, the trailing significand field of the target operand is encoded using preferred DPD codes.

5.6.1 DFP Arithmetic Instructions

All DFP arithmetic instructions are X-form instructions. They all set the FI and FR status flags, and also set the FPSCR_{FPRF} field. Furthermore, they all have an ideal exponent assigned and employ the record bit (Rc).

The arithmetic instructions consist of Add, Divide, Multiply, and Subtract.

DFP Add [Quad]

X-form

dadd FRT,FRA,FRB (Rc=0)
dadd. FRT,FRA,FRB (Rc=1)

59	FRT	FRA	FRB	2	Rc
0	6	11	16	21	31

daddq FRTp,FRAp,FRBp (Rc=0)
daddq. FRTp,FRAp,FRBp (Rc=1)

63	FRTp	FRAp	FRBp	2	Rc
0	6	11	16	21	31

The DFP operand in FRA[p] is added to the DFP operand in FRB[p].

The result is rounded to the target-format precision under control of the DRN (bits 29:31) of the FPSCR. An appropriate form of the rounded result is selected based on the ideal exponent and is placed in FRT[p]. The ideal exponent is the smaller exponent of the two source operands.

Figure 81 summarizes the actions for Add. Figure 81 does not include the setting of the FPSCR_{FPRF} field. The FPSCR_{FPRF} field is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

Special Registers Altered:

FPRF FR FI
FX OX UX XX
VXSNAN VXISI
CR1 (if Rc=1)

DFP Subtract [Quad]

X-form

dsub FRT,FRA,FRB (Rc=0)
dsub. FRT,FRA,FRB (Rc=1)

59	FRT	FRA	FRB	514	Rc
0	6	11	16	21	31

dsubq FRTp,FRAp,FRBp (Rc=0)
dsubq. FRTp,FRAp,FRBp (Rc=1)

63	FRTp	FRAp	FRBp	514	Rc
0	6	11	16	21	31

The DFP operand in FRB[p] is subtracted from the DFP operand in FRA[p].

The result is rounded to the target-format precision under control of the DRN (bits 29:31) of the FPSCR. An appropriate form of the rounded result is selected based on the ideal exponent and is placed in FRT[p]. The ideal exponent is the smaller exponent of the two source operands.

The execution of Subtract is identical to that of Add, except that the operand in FRB participates in the operation with its sign bit inverted. See Figure 81. The table does not include the setting of the FPSCR_{FPRF} field. The FPSCR_{FPRF} field is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

SNaN	V _{XSNAN} : U(a)	V _{XSNAN} : U(a)	V _{XSNAN} : U(a)	V _{XSNAN} : U(a)	V _{XSNAN} : U(a)
Explanation:					
a + b	The value a added to b, rounded to the target-format precision and returned in the appropriate form. (See Section 5.5.11 on page 170)				
+dINF	Default plus infinity.				
-dINF	Default minus infinity.				
dNaN	Default quiet NaN.				
F	All finite numbers, including zeros.				
P(x)	The QNaN of operand x is propagated and placed in FRT[p].				
S(x)	The value x is placed in FRT[p] with the sign set by the rules of algebra. When the source operands have the same sign, the sign of the result is the same as the sign of the operands, including the case when the result is zero. When the operands have opposite signs, the sign of a zero result is positive in all rounding modes, except round toward $-\infty$, in which case, the sign is minus.				
T(x)	The value x is placed in FRT[p].				
U(x)	The SNaN of operand x is converted to the corresponding QNaN and placed in FRT[p].				
V _{XISI}	The Invalid-Operation Exception (VXISI) occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 166 for the exception actions.)				
V _{XSNAN}	The Invalid-Operation Exception (VXSNAN) occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 166 for the exception actions.)

SNaN	V _{XSNAN} : U(a)	V _{XSNAN} : U(a)	V _{XSNAN} : U(a)	V _{XSNAN} : U(a)	V _{XSNAN} : U(a)

Explanation:

- a * b The value a multiplied by b, rounded to the target-format precision and returned in the appropriate form. (See Section 5.5.11 on page 170)
- dINF Default infinity.
- dNaN Default quiet NaN.
- Fn Finite nonzero number (includes both normal and subnormal numbers).
- P(x) The QNaN of operand x is propagated and placed in FRT[p].
- S(x) The value x is placed in FRT[p] with the sign set to the exclusive-OR of the source-operand signs.
- T(x) The value x is placed in FRT[p].
- U(x) The SNaN of operand x is converted to the corresponding QNaN and placed in FRT[p].
- V_{XIMZ}: The Invalid-Operation Exception (VXIMZ) occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 166 for the exception actions.)
- V_{XSNAN}: The Invalid-Operation Exception (VXSNAN) occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 166 for the exception actions.)

Figure 82. Actions: Multiply

DFP Divide [Quad]**X-form**

ddiv FRT,FRA,FRB (Rc=0)

 ddivq. FRTp,FRAp,FRBp (Rc=1)

63	FRTp	FRAp	FRBp	546	Rc
0	6	11	16	21	31

The DFP operand in FRA[p] is divided by the DFP operand in FRB[p].

The result is rounded to the target-format precision under control of the DRN (bits 29:31) of the FPSCR. An appropriate form of the rounded result is selected based on the ideal exponent and is placed in FRT[p]. The ideal exponent is the difference of subtracting the exponent of the divisor from the exponent of the dividend.

Figure 83 summarizes the actions for Divide. Figure 83 does not include the setting of the FPSCR_{FPRF} field. The FPSCR_{FPRF} field is always set to the class and sign of the result, except for an enabled invalid-operation and enabled zero-divide exceptions, in which cases the field remains unchanged.

Figure 83. Actions: Divide

5.6.2 DFP Compare Instructions

The DFP compare instructions consist of the *Compare Ordered* and *Compare Unordered* instructions. The compare instructions do not provide the record bit.

The comparison sets the designated CR field to indicate the result. The $FPSCR_{FPCC}$ is set in the same way.

The codes in the CR field BF and $FPSCR_{FPCC}$ are defined for the DFP compare operations as follows.

Bit	Name	Description
0	FL	$(FRA[p]) < (FRB[p])$
1	FG	$(FRA[p]) > (FRB[p])$
2	FE	$(FRA[p]) = (FRB[p])$
3	FU	$(FRA[p]) ? (FRB[p])$

DFP Compare Unordered [Quad] X-form

dcmpu BF,FRA,FRB

5.6.3 DFP Test Instructions

The DFP test instructions consist of the *Test Data Class*, *Test Data Group*, *Test Exponent*, and *Test Significance* instructions, and they do not provide the record bit.

The test instructions set the designated CR field to indicate the result. The $FPSCR_{FPCC}$ is set in the same way.

DFP Test Data Class [Quad] Z22-form

dtstdc BF,FRA,DCM

59	BF	//	FRA	DCM	194	/
0	6	9	11	16	22	31

dtstdcq BF,FRAp,DCM

63	BF	//	FRAp	DCM	194	/
0	6	9	11	16	22	31

Let the DCM (Data Class Mask) field specify one or more of the 6 possible data classes, where each bit corresponds to a specific data class.

DCM Bit	Data Class
0	Zero
1	Subnormal
2	Normal
3	Infinity
4	Quiet NaN
5	Signaling NaN

CR field BF and $FPSCR_{FPCC}$ are set to indicate the sign of the DFP operand in $FRA[p]$ and whether the data class of the DFP operand in $FRA[p]$ matches any of the data classes specified by DCM.

Field	Meaning
0000	Operand positive with no match
0010	Operand positive with match
1000	Operand negative with no match
1010	Operand negative with match

Special Registers Altered:

CR field BF
FPCC

DFP Test Data Group [Quad] Z22-form

dtstdg BF,FRA,DGM

59	BF	//	FRA	DGM	226	/
0	6	9	11	16	22	31

dtstdgq BF,FRAp,DGM

63	BF	//	FRAp	DGM	226	/
0	6	9	11	16	22	31

Let the DGM (Data Group Mask) field specify one or more of the 6 possible data groups, where each bit corresponds to a specific data group.

The term extreme exponent means either the maximum exponent, X_{max} , or the minimum exponent, X_{min} .

DGM Bit Data Group

0	Zero with non-extreme exponent
1	Zero with extreme exponent
2	Subnormal or (Normal with extreme exponent)
3	Normal with non-extreme exponent and leftmost zero digit in significand
4	Normal with non-extreme exponent and leftmost nonzero digit in significand
5	Special symbol (Infinity, QNaN, or SNaN)

CR field BF and $FPSCR_{FPCC}$ are set to indicate the sign of the DFP operand in $FRA[p]$ and whether the data group of the DFP operand in $FRA[p]$ matches any of the data groups specified by DGM.

Field	Meaning
0000	Operand positive with no match
0010	Operand positive with match
1000	Operand negative with no match
1010	Operand negative with match

Special Registers Altered:

	6	9	11	16	21		31

Let k be the contents of bits 58:63 of FRA that specifies the reference significance.

The number of significant digits of the DFP operand in FRB[p], NSDb, is compared to the reference significance, k. For this instruction, the number of significant digits of the value 0 is considered to be zero. The result of the compare is placed into CR field BF and the FPSCR_{FPCC} as follows.

Bit	Description
0	k ≠ 0 and k < NSDb
1	k ≠ 0 and k > NSDb, or k = 0
2	k ≠ 0 and k = NSDb
3	k ? NSDb

Special Registers Altered:

- CR field BF
- FPCC

Programming Note

The reference significance can be loaded into a FPR using a *Load Float as Integer Word Algebraic* instruction

Actions for Test Significance when the operand in FRB[p] is

F	∞	QNaN	SNaN
C(k: NSDb)	AuoB	AuoB	AuoB

Explanation:

C(k: NSDb)	Algebraic comparison. See the table below.
F	All finite numbers, including zeros.

k ≠ 0 and k > NSDb, or k = 0	AgtB

Figure 87. Actions: Test Significance

5.6.4 DFP Quantum Adjustment Instructions

The *Quantum Adjustment* operations consist of the *Quantize*, *Quantize Immediate*, *Reround*, and *Round To FP Integer* operations.

The *Quantum Adjustment* instructions are Z23-form instructions and have an immediate RMC (Rounding-Mode-Control) field, which specifies the rounding mode used. For *Quantize*, *Quantize Immediate*, and *Reround*, the RMC field contains the primary encoding. For *Round to FP Integer*, the field contains either pri-

mary or secondary encoding, depending on the setting of a RMC-encoding-selection bit. See Section 5.5.2 “Rounding Mode Specification” on page 161 for the definition of RMC encoding.

All *Quantum Adjustment* instructions set the FI and FR status flags, and also set the FPSCR_{FPRF} field. The record bit is provided to each of these instructions. They return the target operand in a form with the ideal exponent.

DFP Quantize Immediate [Quad] Z23-form

dquai TE,FRT,FRB,RMC (Rc=0)
dquai. TE,FRT,FRB,RMC (Rc=1)

59	FRT	TE	FRB	RMC	67	Rc
0	6	11	16	21	23	31

dquaiq TE,FRTp,FRBp,RMC (Rc=0)
dquaiq. TE,FRTp,FRBp,RMC (Rc=1)

63	FRTp	TE	FRBp	RMC	67	Rc
0	6	11	16	21	23	31

The DFP operand in FRB[p] is converted and rounded to the form with the exponent specified by TE based on the rounding mode specified in the RMC field. TE is a 5-bit signed binary integer. The result of that form is placed in FRT[p]. The sign of the result is the same as the sign of the operand in FRB[p]. The ideal exponent is the exponent specified by TE.

When the value of the operand in FRB[p] is greater than $(10^p - 1) \times 10^{TE}$, where p is the format precision, an invalid operation exception is recognized.

When the delivered result differs in value from the operand in FRB[p], an inexact exception is recognized. No underflow exception is recognized by this operation, regardless of the value of the operand in FRB[p].

The FPSCR_{FPRF} field is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

Special Registers Altered:

FPRF FR FI
FX XX
VXSNAN VXCVI
CR1 (if Rc=1)

Programming Note

DFP Quantize Immediate can be used to adjust values to a form having the specified exponent in the range -16 to 15. If the adjustment requires the significand to be shifted left, then:

- if the result would cause overflow from the most significant digit, the result is a default QNaN.;
- otherwise the result is the adjusted value (left shifted with matching exponent).

If the adjustment requires the significand to be shifted right, the result is rounded based on the value of the RMC field.

DFP Quantize Immediate can round a value to a specific number of fractional digits. Consider the computation of sales tax. Values expressed in U.S. dollars have 2 fractional digits, and sales tax rates typically have 3 fractional digits. The product of value and rate will yield 5 fractional digits. For example:

$$39.95 * 0.075 = 2.99625$$

This result needs to be rounded to the penny to compute the correct tax of \$3.00.

The following sequence computes the sales tax assuming the pre-tax total is in FRA and the tax rate is in FRB. The *DFP Quantize Immediate* instruction rounds the product (FRA * FRB) to 2 fractional digits (TE field = -2) using Round to nearest, ties away from 0 (RMC field = 2). The quantized and rounded result is placed in FRT.

```
dumul f0, FRA, FRB
dquai -2, FRT, f0, 2
```

DFP Quantize [Quad]

Z23-form

dqua FRT,FRA,FRB,RMC (Rc=0)
 dqua. FRT,FRA,FRB,RMC (Rc=1)

59	FRT	FRA	FRB	RMC	3	Rc
0	6	11	16	21	23	31

 dquaq. FRTp,FRAp,FRBp,RMC (Rc=1)

63	FRTp	FRAp	FRBp	RMC	3	Rc
0	6	11	16	21	23	31

The DFP operand in register FRB[p] is converted and rounded to the form with the same exponent as that of the DFP operand in FRA[p] based on the rounding mode specified in the RMC field. The result of that form is placed in FRT[p]. The sign of the result is the same as the sign of the operand in FRB[p]. The ideal exponent is the exponent specified in FRA[p].

When the value of the operand in FRB[p] is greater than $(10^p-1) \times 10^{Ea}$, where p is the format precision and Ea is the exponent of the operand in FRA[p], an invalid operation exception is recognized.

When the delivered result differs in value from the operand in FRB[p], an inexact exception is recognized. No

underflow exception is recognized by this operation, regardless of the value of the operand in FRB[p].

Figure 89 and Figure 90 summarize the actions. The tables do not include the setting of the FPSCR_{FPRF} field. The FPSCR_{FPRF} field is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

Special Register Altered:

FPRF FR FI
 FX XX
 VXSNaN VXCVI
 CR1 (if Rc=1)

Programming Note

DFP Quantize can be used to adjust one DFP value (FRB[p]) to a form having the same exponent as a second DFP value (FRA[p]). If the adjustment requires the significand to be shifted left, then:

- if the result would cause overflow from the most significant digit, the result is a default QNaN.;
- otherwise the result is the adjusted value (left shifted with matching exponent).

If the adjustment requires the significand to be shifted right, the result is rounded based on the value of the RMC field. Figure 88 shows examples of these adjustments.

Te = Se		E(0)	W(b)
Te > Se		E(0)	QR(b)

Explanation:

- dNaN Default quiet NaN
- E(0) The value of zero with the exponent value Te is placed in FRT[p].
- L(x) The operand x is converted to the form with the exponent value Te.
- p The precision of the format.
- QR(x) The operand x is rounded to the result of the form with the exponent value Te based on the specified rounding mode. The result of that form is placed in FRT[p].
- Se The exponent of the operand in FRB[p].
- Te The target exponent; FRA[p] for *dqua[q]*, or TE, a 5-bit signed binary integer for *dqua[q]*.
- T(x) The value x is placed in FRT[p].
- V_b The value of the operand in FRB[p].
- W(x) The value and the form of operand x is placed in FRT[p].
- V_{XCVI} : The Invalid-Operation Exception (VXCVI) occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 for actions.)

Figure 90. Actions (part2) Quantize

DFP Reround [Quad] Z23-form

drrnd FRT,FRA,FRB,RMC (Rc=0)
 drrnd. FRT,FRA,FRB,RMC (Rc=1)

59	FRT	FRA	FRB	RMC	35	Rc
0	6	11	16	21	23	31

drrndq FRTp,FRA,FRBp,RMC (Rc=0)
 drrndq. FRTp,FRA,FRBp,RMC (Rc=1)

63	FRTp	FRA	FRBp	RMC	35	Rc
0	6	11	16	21	23	31

Let k be the contents of bits 58:63 of FRA that specifies the reference significance.

When the DFP operand in FRB[p] is a finite number, and if the reference significance is zero, or if the reference significance is nonzero and the number of significant digits of the source operand is less than or equal to the reference significance, then the value and the form of the source operand is placed in FRT[p]. If the reference significance is nonzero and the number of significant digits of the source operand is greater than the reference significance, then the source operand is converted and rounded to the number of significant digits specified in the reference significance based on the rounding mode specified in the RMC field. The result of the form with the specified number of significant digits is placed in FRT[p]. The sign of the result is the same as the sign of the operand in FRB[p].

For this instruction, the number of significant digits of the value 0 is considered to be zero. The ideal exponent is the greater value of the exponent of the operand in FRB[p] and the referenced exponent. The referenced exponent is the resultant exponent if the operand in FRB[p] would have been converted and rounded to the number of significant digits specified in the reference significance based on the rounding mode specified in the RMC field.

If the exponent of the rounded result of the form that has the specified number of significant digits would be greater than X_{\max} , an invalid operation exception (VXCVI) occurs. When the invalid-operation exception occurs, and if the exception is disabled, a default QNaN is returned. When an invalid-operation exception occurs, no inexact exception is recognized.

In the absence of an invalid-operation exception, if the result differs in value from the operand in FRB[p], an inexact exception is recognized.

This operation causes neither an overflow nor an underflow exception.

Figure 92 summarizes the actions for *Reround*. The table does not include the setting of the FPSCR_{FPRF} field. The FPSCR_{FPRF} field is always set to the class and sign of the result, except for an enabled

invalid-operation exception, in which case the field remains unchanged.

Special Registers Altered:

FPRF FR FI
 FX XX
 VXSNaN VXCVI
 CR1

(if Rc=1)

Programming Note

DFP Reround can be used to adjust a DFP value (FRB[p]) to have no more than a specified number (FRA[p]58:63) of significant digits. The result (FRT[p]) is right-justified leaving the specified number of digits and rounded as specified by the RMC field. If rounding increases the number of significant digits, the result is adjusted again (the significand is shifted right 1 digit and the exponent is incremented by 1). Figure 91 has example results from *DFP Reround* for 1, 2, and 10 significant digits.

Programming Note

DFP Reround is primarily used to round a DFP value to a specific number of digits before conversion to string format for printing or display. Another use for *DFP Reround* is to obtain the effective exponent of the most significant digit by specifying a reference significance of 1. The exponent can be extracted and used to compute the number of significant digits or to left-justify a value.

For example, the following sequence computes the number of significant digits and returns it as an integer. FRB is the DFP value for which we want the number of significant digits; f13 contains the reference significance value 0x0000000000000001; and r1 is the stack pointer, with free space for doublewords at offsets -8 and -16. These doublewords are used to transfer the biased exponents from the FPRs to GPRs for integer computation. R3 contains the result of $E(\text{reround}(1, \text{FRA})) - E(\text{FRA}) + 1$, where $E(x)$ represents the biased exponent of x .

```

dxex  f0,FRB
stfd  f0,-16(r1)
drrnd f1,f13,FRB,1 # reround 1 digit toward 0
dxex  f1,f1
stfd  f1,-8(r1)
lfd   r11,-16(r1)
lfd   r3,-8(r1)
subf  r3,r11,r3
addi  r3,r3,1
  
```

Given the value 412.34 the result is $E(4 \times 10^2) - E(41234 \times 10^{-2}) + 1 = (398+2) - (398-2) + 1 = 400 - 396 + 1 = 5$. Additional code is required to detect and handle special values like Subnormal, Infinity, and NAN.

FRA _{58:63} (binary)	FRB	FRT when RMC=1	FRT when RMC=2
1	0.41234 (41234×10^{-5})	0.4 (4×10^{-1})	0.4 (4×10^{-1})
1	4.1234 (41234×10^{-4})	4 (4×10^0)	4 (4×10^0)
1	41.234 (41234×10^{-3})	4 (4×10^1)	4 (4×10^1)
1	412.34 (41234×10^{-2})	4 (4×10^2)	4 (4×10^2)
2	0.491234 (491234×10^{-6})	0.49 (49×10^{-2})	0.49 (49×10^{-2})
2	0.499876 (499876×10^{-6})	0.49 (49×10^{-2})	0.50 (50×10^{-2})
2	0.999876 (999876×10^{-6})	0.99 (99×10^{-2})	1.0 (10×10^{-1})

10	999.999 (999999×10^{-3})	999.999 (999999×10^{-3})	999.999 (999999×10^{-3})
10	9999999999999999 ($9999999999999999 \times 10^0$)	9.999999999E+14 (99999999999×10^5)	1.000000000E+15 (1000000000×10^6)

Figure 91. DFP Reround examples

Programming Note

DFP Reround combined with *DFP Quantize* can be used to left justify a value (as needed by the *frexp* function). FRB is the DFP value for which we want to left justify; f13 contains the reference significance value 0x0000000000000001; and r1 is the stack pointer, with free space for a doubleword at offset -8. This doubleword is used to transfer the biased exponents from the FPR to a GPR, for integer computation. The adjusted biased exponent (+ format precision - 1) is transferred back into an FPR so it can be inserted into the rerounded value. The adjusted rerounded value becomes the quantize reference value. The quantize instruction returns the left justified result in FRT.

```

drnd  f1,f13,FRB,1 # reround 1 digit toward 0
dxex  f0,f1
stfd  f0,-8(r1)
lfd   r11,-8(r1)
addi  r11,r11,15 # biased exp + precision - 1
lfd   r11,-8(r1)
stfd  f0,-8(r1)
diex  f1,f0,f1 # adjust exponent
dqua  FRT,f1,f0,1 # quantize to adjusted
                    exponent

```

m	Number of significant digits in the operand in FRB[p].				
P(x)	The QNaN of operand x is propagated and placed in FRT[p].				
RR(x)	The value x is rounded to the form that has the specified number of significant digits. If $RR(x) \leq (10^k - 1) \times 10^{x_{max}}$, then RR(x) is returned; otherwise an invalid-operation exception is recognized.				
T(x)	The value x is placed in FRT[p].				
U(x)	The SNaN of operand x is converted to the corresponding QNaN and placed in FRT[p].				
V _{XCVI}	The Invalid-Operation Exception (VXCVI) occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 for actions.)				
V _{XSNAN} :	The Invalid-Operation Exception (VXSNAN) occurs. The result is produced only when the exception is disabled. See Section 5.5.10.1 for actions.				
W(x)	The value and the form of x is placed in FRT[p].				

Figure 92. Actions: Reround

DFP Round To FP Integer With Inexact [Quad] Z23-form

drintx R,FRT,FRB,RMC (Rc=0)
drintx. R,FRT,FRB,RMC (Rc=1)

59	FRT	///	R	FRB	RMC	99	Rc
0	6	11	15	16	21	23	31

drintxq R,FRTp,FRBp,RMC (Rc=0)
drintxq. R,FRTp,FRBp,RMC (Rc=1)

63	FRTp	///	R	FRBp	RMC	99	Rc
0	6	11	15	16	21	23	31

The DFP operand in FRB[p] is rounded to a floating-point integer and placed into FRT[p]. The sign of the result is the same as the sign of the operand in FRB[p]. The ideal exponent is the larger value of zero and the exponent of the operand in FRB[p].

The rounding mode used is specified in the RMC field. When the RMC-encoding-selection (R) bit is zero, the RMC field contains the primary encoding; when the bit is one, the field contains the secondary encoding.

In addition to coercion of the converted value to fit the target format, the special rounding used by *Round To FP Integer* also coerces the target exponent to the ideal exponent.

When the operand in FRB[p] is a finite number and the exponent is less than zero, the operand is rounded to the result with an exponent of zero. When the exponent is greater than or equal to zero, the result is set to the numerical value and the form of the operand in FRB[p].

When the result differs in value from the operand in FRB[p], an inexact exception is recognized. No underflow exception is recognized by this operation, regardless of the value of the operand in FRB[p].

Figure 93 summarizes the actions for *Round To FP Integer With Inexact*. The table does not include the setting of the FPSCR_{FPRF} field. The FPSCR_{FPRF} field is always set to the class and sign of the result, except for an enabled invalid-operation, in which case the field remains unchanged.

Special Registers Altered:

FPRF FR FI
FX XX
VXSNAN
CR1 (if Rc=1)

Programming Note

The *DFP Round To FP Integer With Inexact* and *DFP Round To FP Integer With Inexact Quad* instructions can be used to implement the decimal equivalent of the C99 rint function by specifying the primary RMC encoding for round according to FPSCR_{DRN} (R=0, RMC=11). The specification for rint requires the inexact exception be raised if detected.

Operand b in FRB is	Is n not precise (n ≠ b)	Inv.-Op. Exception Enabled	Inexact Exception Enabled	Is n Incremented (nl > bl)	Actions*
-∞	No ¹	-	-	-	T(-dINF), FI ← 0, FR ← 0
F	No	-	-	-	W(n), FI ← 0, FR ← 0
F	Yes	-	No	No	W(n), FI ← 1, FR ← 0, XX ← 1
F	Yes	-	No	Yes	W(n), FI ← 1, FR ← 1, XX ← 1
F	Yes	-	Yes	No	W(n), FI ← 1, FR ← 0, XX ← 1, TX
F	Yes	-	Yes	Yes	W(n), FI ← 1, FR ← 1, XX ← 1, TX
+∞	No ¹	-	-	-	T(+dINF), FI ← 0, FR ← 0
QNaN	No ¹	-	-	-	P(b), FI ← 0, FR ← 0
SNaN	No ¹	No	-	-	U(b), FI ← 0, FR ← 0, VXSNAN ← 1
SNaN	No ¹	Yes	-	-	VXSNAN ← 1, TV

Explanation:

- * Setting of XX and VXSNAN is part of the corresponding exception actions. Also, when an invalid-operation exception occurs, setting of FI and FR is part of the exception actions. (See the sections, “Inexact Exception” and “Invalid Operation Exception” for more details.)
- The actions do not depend on this condition.
- ¹ This condition is true by virtue of the state of some condition to the left of this column.
- dINF Default infinity.
- F All finite numbers, including zeros.
- FI Floating-Point-Fraction-Inexact status flag, FPSCR_{FI}.
- FR Floating-Point-Fraction-Rounded status flag, FPSCR_{FR}.
- n The value derived when the source operand, b, is rounded to an integer using the special rounding for *Round To FP Integer*.
- P(x) The QNaN of operand x is propagated and placed in FRT[p].
- T(x) The value x is placed in FRT[p].
- TV The system floating-point enabled exception error handler is invoked for the invalid-operation exception if the FE0 and FE1 bits in the machine-state register are set to any mode other than the ignore-exception mode.
- TX The system floating-point enabled exception error handler is invoked for the inexact exception if the FE0 and FE1 bits in the machine-state register are set to any mode other than the ignore-exception mode.
- U(x) The SNaN of operand x is converted to the corresponding QNaN and placed in FPT[p].
- W(x) The value x in the form of zero exponent or the source exponent is placed in FRT[p].
- XX Floating-Point-Inexact-Exception status flag, FPSCR_{XX}.

Figure 93. Actions: Round to FP Integer With Inexact

DFP Round To FP Integer Without Inexact [Quad] Z23-form

drintn R,FRT,FRB,RMC (Rc=0)
 drintn. R,FRT,FRB,RMC (Rc=1)

63	FRTp	///	R	FRBp	RMC	227	Rc
0	6	11	15	16	21	23	31

This operation is the same as the *Round To FP Integer With Inexact* operation, except that this operation does not recognize an inexact exception.

Figure 94 summarizes the actions for *Round To FP Integer Without Inexact*. The table does not include the setting of the FPSCR_{FPRF} field. The FPSCR_{FPRF} field is always set to the class and sign of the result, except for an enabled invalid-operation, in which case the field remains unchanged.

Special Registers Altered:

FPRF FR (set to 0) FI (set to 0)
 FX
 VXSNAN
 CR1 (if Rc=1)

Programming Note

The *DFP Round To FP Integer Without Inexact* and *DFP Round To FP Integer Without Inexact Quad* instructions can be used to implement decimal equivalents of several C99 rounding functions by specifying the appropriate R and RMC field values.

Function	R	RMC
Ceil	1	0b00
Floor	1	0b01
Nearbyint0		0b11
Round	0	0b10
Trunc	0	0b01

Note that nearbyint is similar to the rint function but without raising the inexact exception. Similarly ceil, floor, round, and trunc do not require the inexact exception.

Operand b in FRB is	Inv.-Op. Exception Enabled	Actions*
$-\infty$	-	T(-dINF), FI \leftarrow 0, FR \leftarrow 0
F	-	W(n), FI \leftarrow 0, FR \leftarrow 0
$+\infty$	-	T(+dINF), FI \leftarrow 0, FR \leftarrow 0
QNaN	-	P(b), FI \leftarrow 0, FR \leftarrow 0
SNaN	No	U(b), FI \leftarrow 0, FR \leftarrow 0, VXSNAN \leftarrow 1
SNaN	Yes	VXSNAN \leftarrow 1, TV

Explanation:

- * Setting of VXSNAN is part of the corresponding exception actions. Also, when an invalid-operation exception occurs, setting of FI and FR bits is part of the exception actions. (See the sections, "Invalid Operation Exception" for more details.)
- The actions do not depend on this condition.
- dINF Default infinity.
- F All finite numbers, including zeros.
- FI Floating-Point-Fraction-Inexact status flag, FPSCR_{FI}.
- FR Floating-Point-Fraction-Rounded status flag, FPSCR_{FR}.
- n The value derived when the source operand, b, is rounded to an integer using the special rounding for Round-To-FP-Integer.
- P(x) The QNaN of operand x is propagated and placed in FRT[p].
- T(x) The value x is placed in FRT[p].
- TV The system floating-point enabled exception error handler is invoked for the invalid-operation exception if the FE0 and FE1 bits in the machine-state register are set to any mode other than the ignore-exception mode.
- U(x) The SNaN of operand x is converted to the corresponding QNaN and placed in FPT[p].
- W(x) The value x in the form of zero exponent or the source exponent is placed in FRT[p].

Figure 94. Actions: Round to FP Integer Without Inexact

5.6.5 DFP Conversion Instructions

The DFP conversion instructions consist of data-format conversion instructions and data-type conversion instructions. They are all X-form instructions and employ the record bit (Rc).

5.6.5.1 DFP Data-Format Conversion Instructions

The data-format conversion instructions consist of *Convert To DFP Long*, *Convert To DFP Extended*, *Round To DFP Short*, and *Round To DFP Long*. Figure 95 summarizes the actions for these instructions.

Programming Note

DFP does not provide operations on short operands, so they must be converted to long format, and then converted back to be stored. Preserving correct signaling NaN semantics requires that signaling NaNs be propagated from the source to the result without recognizing an exception during widening from short to long or narrowing from long to short. Because DFP does not provide equivalents to the FP *Load Floating-Point Single* and *Store Floating-Point Single* functions, the widening is performed by loading the DFP short value with a *Load Floating as Integer Word Indexed* followed by a *DFP Convert to DFP Long*, and narrowing is performed by a *DFP Round to DFP Short* followed by a *Store Floating-Point as Integer Word Indexed*. If the SNaN or infinity in DFP short format uses the preferred DPD encoding, then converting this operand to DFP long format and back to DFP short will result in the original bit pattern.

Instruction	Actions when operand b in FRB[p] is			
	F	∞	QNaN	SNaN
Convert To DFP Long	$T(b)^1$	$P(b)^{2,4}$	$P(b)^{2,4}$	$P(b)^{3,4}$
Convert To DFP Extended	$T(b)^1$	$T(dINF)$	$P(b)^{2,4}$	$V_{XSNAN}: U(b)^{2,4}$
Round To DFP Short	$R(b)^1$	$P(b)^{2,5}$	$P(b)^{2,5}$	$P(b)^{3,5}$
Round To DFP Long	$R(b)^1$	$T(dINF)$	$P(b)^{2,5}$	$V_{XSNAN}: U(b)^{2,5}$

Explanation:

- 1The ideal exponent is the exponent of the source operand.
- 2Bits 5:N-1 of the N-bit combination field are set to zero.
- 3Bit 5 of the N-bit combination field is set to one. Bits 6:N-1 of the combination field are set to zero.
- 4The trailing significand field is padded on the left with zeros.
- 5Leftmost digits in the trailing significand field are removed.
- dINFDefault infinity.
- FAll finite numbers, including zeros.
- P(x)The special symbol in operand x is propagated into FRT[p].
- R(x)The value x is rounded to the target-format precision; see Section 5.5.11
- T(x)The value x is placed in FRT[p].
- U(x)The SNaN of operand x is converted to the corresponding QNaN.
- V_{XSNAN} The Invalid-Operation Exception (VXSNAN) occurs. The result is produced only when the exception is disabled. See Section 5.5.10.1 for actions.

Figure 95. Actions: Data-Format Conversion Instructions

5.6.5.2 DFP Data-Type Conversion Instructions

The DFP data-type conversion instructions are used to convert data type between DFP and fixed.

The data-type conversion instructions consist of *Convert From Fixed* and *Convert To Fixed*.

DFP Convert From Fixed

X-form

dcffix FRT,FRB (Rc=0)
dcffix. FRT,FRB (Rc=1)

59	FRT	///	FRB	802	Rc
0	6	11	16	21	31

The 64-bit signed binary integer in FRB is converted and rounded to a DFP Long value and placed into FRT. The sign of the result is the same as the sign of the source operand. The ideal exponent is zero.

If the source operand is a zero, then a plus zero with a zero exponent is returned.

The FPSCR_{FPRF} field is set to the class and sign of the result.

Special Registers Altered:

FPRF FR FI
FX XX
CR1 (if Rc=1)

DFP Convert From Fixed Quad

X-form

dcffixq FRT_p,FRB (Rc=0)
dcffixq. FRT_p,FRB (Rc=1)

63	FRT _p	///	FRB	802	Rc
0	6	11	16	21	31

The 64-bit signed binary integer in FRB is converted and rounded to a DFP Extended value and placed into FRT_p. The sign of the result is the same as the sign of the source operand. The ideal exponent is zero.

If the source operand is a zero, then a plus zero with a zero exponent is returned.

The FPSCR_{FPRF} field is set to the class and sign of the result.

Special Registers Altered:

FPRF FR (undefined) FI (undefined)

dctfixq. FRT,FRB_p (Rc=1)

63	FRT	///	FRB _p	290	Rc
0	6	11	16	21	31

The DFP operand in FRB_p is rounded to an integer value and is placed into FRT in the 64-bit signed binary integer format. The sign of the result is the same as the sign of the source operand, except when the source operand is a NaN or a zero.

Figure 96 summarizes the actions for *Convert To Fixed*.

Special Registers Altered:

FPRF (undefined) FR FI
FX XX
VXSNAN VXCVI
CR1 (if Rc=1)

Programming Note

It is recommended that software pre-round the operand to a floating-point integral using **drintx[q]** or **drintn[q]** is a rounding mode other than the current rounding mode specified by FPSCR_{DRN} is needed. Saving, modifying and restoring the FPSCR just to temporarily change the rounding mode is less efficient than just employing drintx[p] or drint[p] which override the current rounding mode using an immediate control field.

For example if the desired function rounding is Round to Nearest, Ties away from 0 but the default rounding (from FPSCR_{DRN}) is Round to Nearest, Ties to Even then following is preferred.

```
drintn    0, f1, f1, 2
dctfix    f1, f1
```

Operand b in FRB[p] is	q is	Is n not precise (n ≠ b)	Inv.-Op. Except. Enabled	Inexact Except. Enabled	Is n Incremented (n > b)	Actions *

SNaN	-	-	Yes	-	-	VXCVI ← 1, VXSNaN ← 1, TV

Explanation:

- * Setting of XX, VXCVI, and VXSNaN is part of the corresponding exception actions. Also, when an invalid-operation exception occurs, setting of FI and FR bits is part of the exception actions. (See the sections, “Inexact Exception” and “Invalid Operation Exception” for more details.)
- The actions do not depend on this condition.
- FI Floating-Point-Fraction-Inexact status flag, FPSCR_{FI}.
- FR Floating-Point-Fraction-Rounded status flag, FPSCR_{FR}.
- MN Maximum negative number representable by the 64-bit binary integer format
- MP Maximum positive number representable by the 64-bit binary integer format.
- n The value q converted to a fixed-point result.
- q The value derived when the source value b is rounded to an integer using the specified rounding mode
- T(x) The value x is placed in FRT[p].
- TV The system floating-point enabled exception error handler is invoked for the invalid-operation exception if the FE0 and FE1 bits in the machine-state register are set to any mode other than the ignore-exception mode.
- TX The system floating-point enabled exception error handler is invoked for the inexact exception if the FE0 and FE1 bits in the machine-state register are set to any mode other than the ignore-exception mode.
- VXCVI The FPSCR_{VXCVI} invalid operation exception status bit.
- VXSNaN The FPSCR_{VXSNaN} invalid operation exception status bit.
- XX Floating-Point-Inexact-Exception status flag, FPSCR_{XX}.

Figure 96. Actions: Convert To Fixed

5.6.6 DFP Format Instructions

The DFP format instructions are used to compose or decompose a DFP operand. A source operand of SNaN does not cause an invalid-operation exception. All format instructions employ the record bit (Rc).

The format instructions consist of *Decode DPD To BCD*, *Encode BCD To DPD*, *Extract Biased Exponent*, *Insert Biased Exponent*, *Shift Significand Left Immediate*, and *Shift Significand Right Immediate*.

DFP Decode DPD To BCD [Quad] X-form

ddedpd SP,FRT,FRB (Rc=0)
ddedpd. SP,FRT,FRB (Rc=1)

59	FRT	SP	///	FRB	322	Rc
0	6	11	13	16	21	31

ddedpdq SP,FRTp,FRBp (Rc=0)
ddedpdq. SP,FRTp,FRBp (Rc=1)

63	FRTp	SP	///	FRBp	322	Rc
0	6	11	13	16	21	31

A portion of the significand of the DFP operand in FRB[p] is converted to a signed or unsigned BCD number depending on the SP field. For infinity and NaN, the significand is considered to be the contents in the trailing significand field padded on the left by a zero digit.

SP₀ = 0 (unsigned conversion)

The rightmost 16 digits of the significand (32 digits for **ddedpdq**) is converted to an unsigned BCD number and the result is placed into FRT[p].

SP₀ = 1 (signed conversion)

The rightmost 15 digits of the significand (31 digits for **ddedpdq**) is converted to a signed BCD number with the same sign as the DFP operand, and the result is placed into FRT[p]. If the DFP operand is negative, the sign is encoded as 0b1101. If the DFP operand is positive, SP₁ indicates which preferred plus sign encoding is used. If SP₁ = 0, the plus sign is encoded as 0b1100 (the option-1 preferred sign code), otherwise the plus sign is encoded as 0b1111 (the option-2 preferred sign code).

Special Registers Altered:

DFP Encode BCD To DPD [Quad] X-form

denbcd S,FRT,FRB (Rc=0)
denbcd. S,FRT,FRB (Rc=1)

59	FRT	S	///	FRB	834	Rc
0	6	11	12	16	21	31

denbcdq S,FRTp,FRBp (Rc=0)
denbcdq. S,FRTp,FRBp (Rc=1)

63	FRTp	S	///	FRBp	834	Rc
0	6	11	12	16	21	31

The signed or unsigned BCD operand, depending on the S field, in FRB[p] is converted to a DFP number. The ideal exponent is zero.

S = 0 (unsigned BCD operand)

The unsigned BCD operand in FRB[p] is converted to a positive DFP number of the same magnitude and the result is placed into FRT[p].

S = 1 (signed BCD operand)

The signed BCD operand in FRB[p] is converted to the corresponding DFP number and the result is placed into FRT[p].

If an invalid BCD digit or sign code is detected in the source operand, an invalid-operation exception (VXCVI) occurs.

FPSCR_{FPRF} is set to the class and sign of the result, except for Invalid Operation Exception when FPSCR_{VE}=1.

Special Registers Altered:

dscliq. FRTp,FRAp,SH (Rc=1)

63	FRTp	FRAp	SH	66	Rc
0	6	11	16	22	31

The significand of the DFP operand in FRA[p] is shifted left SH digits. For a NaN or infinity, all significand digits are in the trailing significand field. SH is a 6-bit unsigned binary integer. Digits shifted out of the leftmost digit are lost. Zeros are supplied to the vacated positions on the right. The result is placed into FRT[p]. The sign of the result is the same as the sign of the source operand in FRA[p].

If the source operand in FRA[p] is a finite number, the exponent of the result is the same as the exponent of the source operand.

For an Infinity, QNaN or SNaN result, the target format's N-bit combination field is set as follows.

- For an Infinity result,
 - the leftmost 5 bits are set to 0b11110, and
 - the rightmost N-5 bits are set to zero.
- For a QNaN result,
 - the leftmost 5 bits are set to 0b11111,
 - bit 5 is set to zero, and
 - the rightmost N-6 bits are set to zero.
- For an SNaN result,
 - the leftmost 5 bits are set to 0b11111,
 - bit 5 is set to one, and
 - the rightmost N-6 bits are set to zero.

Special Registers Altered:

Explanation:											
#	FI and FR are set to zeros for these instructions.										
-	Not applicable.										
1	A unique definition of the FPSCR _{FPC} field is provided for the instruction.										
2	These are the only instructions that may generate an SNaN and also set the FPSCR _{FPRF} field. Since the BFP FPSCR _{FPRF} field does not include a code for SNaN, these instructions cause the need for redefining the FPSCR _{FPRF} field for DFP.										
DCM	A 6-bit immediate operand specifying the data-class mask.										
DGM	A 6-bit immediate operand specifying the data-group mask.										
G	An SNaN can be generated as the target operand.										
IE	An ideal exponent is defined for the instruction.										
FI	Setting of the FPSCR _{FI} flag.										
FR	Setting of the FPSCR _{FR} flag.										
N	No.										
O	An overflow exception may be recognized.										
Rc	The record bit, Rc, is provided to record FPSCR _{0:3} in CR field 1.										
RE	The trailing significand field is reencoded using preferred DPD encodings. The preferred DPD encoding are also used for propagated NaNs, or converted NaNs and infinities.										
RMC	A 2-bit immediate operand specifying the rounding-mode control.										
S	An one-bit immediate operand specifying if the operation is signed or unsigned.										
SP	A two-bit immediate operand: one bit specifies if the operation is signed or unsigned and, for signed operations, another bit specifies which preferred plus sign code is generated.										
U	An underflow exception may be recognized.										
V	An invalid-operation exception may be recognized.										
Vs	An input operand of SNaN causes an invalid-operation exception.										
X	An inexact exception may be recognized.										
Y	Yes.										
U	Undefined										
Z	A zero-divide exception may be recognized.

6.1 Vector Facility Overview

This chapter describes the registers and instructions that make up the Vector Facility.

6.2 Chapter Conventions

6.2.1 Description of Instruction Operation

The following notation, in addition to that described in Section 1.3.2, is used in this chapter. Additional RTL functions are described in Appendix C.

Notation Meaning

$x ? y : z$	if the value of x is true, then the value of y , otherwise the value z .
$+_{\text{int}}$	Integer addition.
$+_{\text{fp}}$	Floating-point addition.
$-_{\text{fp}}$	Floating-point subtraction.
\times_{sui}	Multiplication of a signed-integer (first operand) by an unsigned-integer (second operand).
\times_{fp}	Floating-point multiplication.
$=_{\text{int}}$	Integer equals relation.
$=_{\text{fp}}$	Floating-point equals relation.
$<_{\text{ui}}, \leq_{\text{ui}}, >_{\text{ui}}, \geq_{\text{ui}}$	Unsigned-integer comparison relations.
$<_{\text{si}}, \leq_{\text{si}}, >_{\text{si}}, \geq_{\text{si}}$	Signed-integer comparison relations.
$<_{\text{fp}}, \leq_{\text{fp}}, >_{\text{fp}}, \geq_{\text{fp}}$	Floating-point comparison relations.
$\text{LENGTH}(x)$	Length of x , in bits. If x is the word “element”, $\text{LENGTH}(x)$ is the length, in bits, of the element implied by the instruction mnemonic.
$x \ll y$	Result of shifting x left by y bits, filling vacated bits with zeros. $b \leftarrow \text{LENGTH}(x)$ $\text{result} \leftarrow (y < b) ? (x_{y:b-1} \parallel 0^y) : b_0$
$x \gg_{\text{ui}} y$	Result of shifting x right by y bits, filling vacated bits with zeros. $b \leftarrow \text{LENGTH}(x)$ $\text{result} \leftarrow (y < b) ? (x_0 \parallel x_{0:(b-y)-1}) : b_0$
$x \gg y$	Result of shifting x right by y bits, filling vacated bits with copies of bit 0 (sign bit) of x . $b \leftarrow \text{LENGTH}(x)$ $\text{result} \leftarrow (y < b) ? (x_0 \parallel x_{0:(b-y)-1}) : b_{x_0}$
$x \lll y$	Result of rotating x left by y bits. $b \leftarrow \text{LENGTH}(x)$ $\text{result} \leftarrow x_{y:b-1} \parallel x_{0:y-1}$
$\text{Chop}(x, y)$	Result of extending the right-most y bits of x on the left with zeros. $\text{result} \leftarrow x \& ((1 \ll y) - 1)$
$\text{EXTZ}(x)$	Result of extending x on the left with zeros. $b \leftarrow \text{LENGTH}(x)$ $\text{result} \leftarrow x \& ((1 \ll b) - 1)$

$\text{Clamp}(x, y, z)$

x is interpreted as a signed integer. If the value of x is less than y , then the value y is returned, else if the value of x is greater than z , the value z is returned, else the value x is returned.

```
if (x < y) then
  result ← y
  VSCRSAT ← 1
else if (x > z) then
  result ← z
  VSCRSAT ← 1
else result ← x
```

$\text{RoundToSPIntCeil}(x)$

The value x if x is a single-precision floating-point integer; otherwise the smallest single-precision floating-point integer that is greater than x .

$\text{RoundToSPIntFloor}(x)$

The value x if x is a single-precision floating-point integer; otherwise the largest single-precision floating-point integer that is less than x .

$\text{RoundToSPIntNear}(x)$

The value x if x is a single-precision floating-point integer; otherwise the single-precision floating-point integer that is nearest in value to x (in case of a tie, the even single-precision floating-point integer is used).

$\text{RoundToSPIntTrunc}(x)$

The value x if x is a single-precision floating-point integer; otherwise the largest single-precision floating-point integer that is less than x if $x > 0$, or the smallest single-precision floating-point integer that is greater than x if $x < 0$.

$\text{RoundToNearSP}(x)$

The single-precision floating-point number that is nearest in value to the infinitely-precise floating-point intermediate result x (in case of a tie, the single-precision floating-point value with the least-significant bit equal to 0 is used).

$\text{ReciprocalEstimateSP}(x)$

A single-precision floating-point estimate of the reciprocal of the single-precision floating-point number x .

$\text{ReciprocalSquareRootEstimateSP}(x)$

A single-precision floating-point estimate of the reciprocal of the square root of the single-precision floating-point number x .

$\text{LogBase2EstimateSP}(x)$

A single-precision floating-point estimate of the base 2 logarithm of the single-precision floating-point number x .

$\text{Power2EstimateSP}(x)$

A single-precision floating-point estimate of the 2 raised to the power of the single-precision floating-point number x .

Figure 99. Vector Register elements

6.3 Vector Facility Registers

6.3.1 Vector Registers

There are 32 Vector Registers (VRs), each containing 128 bits. See Figure 100. All computations and other data manipulation are performed on data residing in Vector Registers, and results are placed into a VR.

Figure 100. Vector Registers

Depending on the instruction, the contents of a Vector Register are interpreted as a sequence of equal-length elements (bytes, halfwords, or words) or as a quadword. Each of the elements is aligned at its natural boundary within the Vector Register, as shown in Figure 99. Many instructions perform a given operation in parallel on all elements in a Vector Register. Depending on the instruction, a byte, halfword, or word element can be interpreted as a signed-integer, an unsigned-integer, or a logical value; a word element can also be interpreted as a single-precision floating-point value. In the instruction descriptions, phrases like “signed-integer word element” are used as shorthand for “word element, interpreted as a signed-integer”.

Load and *Store* instructions are provided that transfer a byte, halfword, word, or quadword between storage and a Vector Register.

6.3.2 Vector Status and Control Register

The Vector Status and Control Register (VSCR) is a special 32-bit register (not an SPR) that is read and written in a manner similar to the FPSCR in the Power

ISA scalar floating-point unit. Special instructions (*mfvsr* and *mtvsr*) are provided to move the VSCR from and to a vector register. When moved to or from a vector register, the 32-bit VSCR is right justified in the 128-bit vector register. When moved to a vector register, bits 0-95 of the vector register are cleared (set to 0).

Figure 101. Vector Status and Control Register

The bit definitions for the VSCR are as follows.

Bit(s) Description

96:110 Reserved

111 **Vector Non-Java Mode (NJ)**

This bit controls how denormalized values are handled by *Vector Floating-Point* instructions.

0 Denormalized values are handled as specified by Java and the IEEE standard; see Section 6.6.1.

1 If an element in a source VR contains a denormalized value, the value 0 is used instead. If an instruction causes an Underflow Exception, the corresponding element in the target VR is set to 0. In both cases the 0 has the same sign as the denormalized or underflowing value.

112:126 Reserved

127 **Vector Saturation (SAT)**

Every vector instruction having “Saturate” in its name implicitly sets this bit to 1 if any result of that instruction “saturates”; see Section 6.8.

mtvsr can alter this bit explicitly. This bit is sticky; that is, once set to 1 it remains set to 1 until it is set to 0 by an *mtvsr* instruction.

After the *mfvsr* instruction executes, the result in the target vector register will be architecturally precise. That is, it will reflect all updates to the SAT bit that could have been made by vector instructions logically preceding it in the program flow, and further, it will not reflect any SAT updates that may be made to it by vector instructions logically following it in the program flow. To implement this, processors may choose to make the

mfvscr instruction execution serializing within the vector unit, meaning that it will stall vector instruction execution until all preceding vector instructions are complete and have updated the architectural machine state. This is permitted in order to simplify implementation of the sticky status bit (SAT) which would otherwise be difficult to implement in an out-of-order execution machine. The implication of this is that reading the VSCR can be much slower than typical Vector instructions, and therefore care must be taken in reading it, as advised in Section 6.5.1, to avoid performance problems.

The *mtvscr* is context synchronizing. This implies that all Vector instructions logically preceding an *mtvscr* in the program flow will execute in the architectural context (NJ mode) that existed prior to completion of the *mtvscr*, and that all instructions logically following the *mtvscr* will execute in the new context (NJ mode) established by the *mtvscr*.

6.3.3 VR Save Register

The VR Save Register (VRSAVE) is a 32-bit register in the fixed-point processor provided for application and operating system use; see Section 3.2.3.

Programming Note

The VRSAVE register can be used to indicate which VRs are currently being used by a program. If this is done, the operating system could save only those VRs when an “interrupt” occurs (see Book III), and could restore only those VRs when resuming the interrupted program.

If this approach is taken it must be applied rigorously; if a program fails to indicate that a given VR is in use, software errors may occur that will be difficult to detect and correct because they are timing-dependent.

Some operating systems save and restore VRSAVE only for programs that also use other vector registers.

6.4 Vector Storage Access Operations

The *Vector Storage Access* instructions provide the means by which data can be copied from storage to a Vector Register or from a Vector Register to storage. Instructions are provided that access byte, halfword, word, and quadword storage operands. These instructions differ from the fixed-point and floating-point *Storage Access* instructions in that vector storage operands are assumed to be aligned, and vector storage accesses are performed as if the appropriate number of low-order bits of the specified effective address (EA) were zero. For example, the low-order bit of EA is ignored for halfword *Vector Storage Access* instructions, and the low-order four bits of EA are ignored for quadword *Vector Storage Access* instructions. The effect is to load or store the storage operand of the specified length that contains the byte addressed by EA.

If a storage operand is unaligned, additional instructions must be used to ensure that the operand is correctly placed in a Vector Register or in storage. Instructions are provided that shift and merge the contents of two Vector Registers, such that an unaligned quadword storage operand can be copied between storage and the Vector Registers in a relatively efficient manner.

As shown in Figure 99, the elements in Vector Registers are numbered; the high-order (or most significant) byte element is numbered 0 and the low-order (or least significant) byte element is numbered 15. The numbering affects the values that must be placed into the permute control vector for the *Vector Permute* instruction in order for that instruction to achieve the desired effects, as illustrated by the examples in the following subsections.

A vector quadword *Load* instruction for which the effective address (EA) is quadword-aligned places the byte in storage addressed by EA into byte element 0 of the target Vector Register, the byte in storage addressed by EA+1 into byte element 1 of the target Vector Register, etc. Similarly, a vector quadword *Store* instruction for which the EA is quadword-aligned places the contents of byte element 0 of the source Vector Register into the byte in storage addressed by EA, the contents of byte element 1 of the source Vector Register into the byte in storage addressed by EA+1, etc.

Figure 102 shows an aligned quadword in storage. Figure 103 shows the result of loading that quadword into a Vector Register or, equivalently, shows the contents that must be in a Vector Register if storing that Vector Register is to produce the storage contents shown in Figure 102.

When an aligned byte, halfword, or word storage operand is loaded into a Vector Register, the element (byte,

halfword, or word respectively) that receives the data is the element that would have received the data had the entire aligned quadword containing the storage operand and addressed by EA been loaded. Similarly, when a byte, halfword, or word element in a Vector Register is stored into an aligned storage operand (byte, halfword, or word respectively), the element selected to be stored is the element that would have been stored into the storage operand addressed by EA had the entire Vector Register been stored to the aligned quadword containing the storage operand addressed by EA. (Byte storage operands are always aligned.)

For aligned byte, halfword, and word storage operands, if the corresponding element number is known when the program is written, the appropriate *Vector Splat* and *Vector Permute* instructions can be used to copy or replicate the data contained in the storage operand after loading the operand into a Vector Register. An example of this is given in the Programming Note for *Vector Splat*; see page 226. Another example is to replicate the element across an entire Vector Register before storing it into an arbitrary aligned storage operand of the same length; the replication ensures that the correct data are stored regardless of the offset of the storage operand in its aligned quadword in storage.

Figure 105. Vector Register contents

6.4.1 Accessing Unaligned Storage Operands

Figure 104 shows an unaligned quadword storage operand that spans two aligned quadwords. In the remainder of this section, the aligned quadword that contains the most significant bytes of the unaligned quadword is called the most significant quadword (MSQ) and the aligned quadword that contains the least significant bytes of the unaligned quadword is called the least significant quadword (LSQ). Because

the *Vector Storage Access* instructions ignore the low-order bits of the effective address, the unaligned quadword cannot be transferred between storage and a Vector Register using a single instruction. The remainder of this section gives examples of accessing unaligned quadword storage operands. Similar sequences can be used to access unaligned halfword and word storage operands.

Programming Note

The sequence of instructions given below is one approach that can be used to load the unaligned quadword shown in Figure 104 into a Vector Register. In Figure 105 Vhi and Vlo are the Vector Registers that will receive the most significant quadword and least significant quadword respectively. VRT is the target Vector Register.

After the two quadwords have been loaded into Vhi and Vlo, using *Load Vector Indexed* instructions, the alignment is performed by shifting the 32-byte quantity Vhi || Vlo left by an amount determined by the address of the first byte of the desired data. The shifting is done using a *Vector Permute* instruction for which the permute control vector is generated by a *Load Vector for Shift Left* instruction. The *Load Vector for Shift Left* instruction uses the same address specification as the *Load Vector Indexed* instruction that loads the Vhi register; this is the address of the desired unaligned quadword.

The following sequence of instructions copies the unaligned quadword storage operand into register Vt.

```
# Assumptions:
# Rb != 0 and contents of Rb = 0xB
lvx      Vhi,0,Rb      # load MSQ
lvsl     Vp,0,Rb      # set permute control vector
addi     Rb,Rb,16     # address of LSQ
lvx      Vlo,0,Rb     # load LSQ
vperm    Vt,Vhi,Vlo,Vp # align the data
```

The procedure for storing an unaligned quadword is essentially the reverse of the procedure for loading one. However, a read-modify-write sequence is required that inserts the source quadword into two aligned quadwords in storage. The quadword to be stored is assumed to be in Vs; see Figure 105 The contents of Vs are shifted right and split into two parts,

each of which is merged (using a *Vector Select* instruction) with the current contents of the two aligned quadwords (MSQ and LSQ) that will contain the most significant bytes and least significant bytes, respectively, of the unaligned quadword. The resulting two quadwords are stored using *Store Vector Indexed* instructions. A *Load Vector for Shift Right* instruction is used to generate the permute control vector that is used for the shifting. A single register is used for the “shifted” contents; this is possible because the “shifting” is done by means of a right rotation. The rotation is accomplished by specifying Vs for both components of the *Vector Permute* instruction. In addition, the same permute control vector is used on a sequence of 1s and 0s to generate the mask used by the *Vector Select* instructions that do the merging.

The following sequence of instructions copies the contents of Vs into an unaligned quadword in storage.

```
# Assumptions:
# Rb != 0 and contents of Rb = 0xB
lvx      Vhi,0,Rb      # load current MSQ
lvsl     Vp,0,Rb      # set permute control vector
addi     Rb,Rb,16     # address of LSQ
lvx      Vlo,0,Rb     # load current LSQ
vspltisb V1s,-1      # generate the select mask bits
vspltisb V0s,0
vperm    Vmask,V0s,V1s,Vp
                                     # generate the select mask
vperm    Vs,Vs,Vs,Vp  # right rotate the data
vsel     Vlo,Vs,Vlo,Vmask # insert LSQ component
vsel     Vhi,Vhi,Vs,Vmask # insert MSQ component
stvx     Vlo,0,Rb     # store LSQ
addi     Rb,Rb,-16    # address of MSQ
stvx     Vhi,0,Rb     # store MSQ
```

6.5 Vector Integer Operations

Many of the instructions that produce fixed-point integer results have the potential to compute a result value that cannot be represented in the target format. When this occurs, this unrepresentable intermediate value is converted to a representable result value using one of the following methods.

1. The high-order bits of the intermediate result that do not fit in the target format are discarded. This method is used by instructions having names that include the word "Modulo".
2. The intermediate result is converted to the nearest value that is representable in the target format (i.e., to the minimum or maximum representable value, as appropriate). This method is used by instructions having names that include the word "Saturate". An intermediate result that is forced to the minimum or maximum representable value as just described is said to "saturate".

An instruction for which an intermediate result saturates causes $VSCR_{SAT}$ to be set to 1; see Section 6.3.2.

3. If the intermediate result includes non-zero fraction bits it is rounded up to the nearest fixed-point integer value. This method is used by the six *Vector Average Integer* instructions and by the *Vector Multiply-High-Round-Add Signed Halfword Saturate* instruction. The latter instruction then uses method 2, if necessary.

Programming Note

Because $VSCR_{SAT}$ is sticky, it can be used to detect whether any instruction in a sequence of "Saturate"-type instructions produced an inexact result due to saturation. For example, the contents of the VSCR can be copied to a VR (*mfvscr*), bits other than the SAT bit can be cleared in the VR (*vand* with a constant), the result can be compared to zero setting CR6 (*vcmpequb.*), and a branch can be taken according to whether $VSCR_{SAT}$ was set to 1 (*Branch Conditional* that tests CR field 6).

Testing $VSCR_{SAT}$ after each "Saturate"-type instruction would degrade performance considerably. Alternative techniques include the following:

- Retain sufficient information at "checkpoints" that the sequence of computations performed between one checkpoint and the next can be redone (more slowly) in a manner that detects exactly when saturation occurs. Test $VSCR_{SAT}$ only at checkpoints, or when redoing a sequence of computations that saturated.
- Perform intermediate computations using an element length sufficient to prevent saturation, and then use a *Vector Pack Integer Saturate* instruction to pack the final result to the desired length. (Vector Pack Integer Saturate causes results to saturate if necessary, and sets $VSCR_{SAT}$ to 1 if any result saturates.)

6.5.1 Integer Saturation

Saturation occurs whenever the result of a saturating instruction does not fit in the result field. Unsigned saturation clamps results to zero (0) on underflow and to the maximum positive integer value (2^{n-1} , e.g. 255 for byte fields) on overflow. Signed saturation clamps results to the smallest representable negative number (-2^{n-1} , e.g. -128 for byte fields) on underflow, and to the largest representable positive number ($2^{n-1}-1$, e.g. +127 for byte fields) on overflow.

In most cases, the simple maximum/minimum saturation performed by the vector instructions is adequate. However, sometimes, e.g. in the creation of very high quality images, more complex saturation functions must be applied. To support this, the Vector facility provides a mechanism for detecting that saturation has occurred. The VSCR has a bit, the SAT bit, which is set to a one (1) anytime any field in a saturating instruction saturates. The SAT bit can only be cleared by explicitly writing zero to it. Thus SAT accumulates a summary result of any integer overflow or underflow that occurs on a saturating instruction.

Borderline cases that generate results equal to saturation values, for example unsigned $0+0=0$ and unsigned byte $1+254=255$, are not considered saturation conditions and do not cause SAT to be set.

The SAT bit can be set by the following types of instructions:

- Move To VSCR
- Vector Add Integer with Saturation
- Vector Subtract Integer with Saturation
- Vector Multiply-Add Integer with Saturation
- Vector Multiply-Sum with Saturation
- Vector Sum-Across with Saturation
- Vector Pack with Saturation
- Vector Convert to Fixed-point with Saturation

Note that only instructions that explicitly call for “saturation” can set SAT. “Modulo” integer instructions and floating-point arithmetic instructions never set SAT.

Programming Note

The SAT state can be tested and used to alter program flow by moving the VSCR to a vector register (with *mfvschr*), then masking out bits 0:126 (to clear undefined and reserved bits) and performing a vector compare equal-to unsigned byte w/record (*vcmpequb*) with zero to get a testable value into the condition register for consumption by a subsequent branch.

Since *mfvschr* will be slow compared to other Vector instructions, reading and testing SAT after each instruction would be prohibitively expensive. Therefore, software is advised to employ strategies that minimize checking SAT. For example: checking SAT periodically and backtracking to the last checkpoint to identify exactly which field in which instruction saturated; or, working in an element size sufficient to prevent any overflow or underflow during intermediate calculations, then packing down to the desired element size as the final operation (the vector pack instruction saturates the results and updates SAT when a loss of significance is detected).

6.6 Vector Floating-Point Operations

6.6.1 Floating-Point Overview

Unless $VSCR_{NJ}=1$ (see Section 6.3.2), the floating-point model provided by the Vector Facility conforms to The Java Language Specification (hereafter referred to as “Java”), which is a subset of the default environment specified by the IEEE standard (i.e., by ANSI/IEEE Standard 754-1985, “IEEE Standard for Binary Floating-Point Arithmetic”). For aspects of floating-point behavior that are not defined by Java but are defined by the IEEE standard, vector floating-point conforms to the IEEE standard. For aspects of floating-point behavior that are defined neither by Java nor by the IEEE standard but are defined by the “C9X Floating-Point Proposal” (hereafter referred to as “C9X”), vector floating-point conforms to C9X.

The single-precision floating-point data format, value representations, and computational models defined in Chapter 4. “Floating-Point Facility [Category: Floating-Point]” on page 105 apply to vector floating-point except as follows.

- In general, no status bits are set to reflect the results of floating-point operations. The only exception is that $VSCR_{SAT}$ may be set by the *Vector Convert To Fixed-Point Word* instructions.
- With the exception of the two *Vector Convert To Fixed-Point Word* instructions and three of the four *Vector Round to Floating-Point Integer* instructions, all vector floating-point instructions that round use the rounding mode Round to Nearest.
- Floating-point exceptions (see Section 6.6.2) cannot cause the system error handler to be invoked.

Programming Note

If a function is required that is specified by the IEEE standard, is not supported by the Vector Facility, and cannot be emulated satisfactorily using the functions that are supported by the Vector Facility, the functions provided by the Floating-Point Facility should be used; see Chapter 4.

6.6.2 Floating-Point Exceptions

The following floating-point exceptions may occur during execution of vector floating-point instructions.

- NaN Operand Exception
- Invalid Operation Exception
- Zero Divide Exception
- Log of Zero Exception
- Overflow Exception
- Underflow Exception

If an exception occurs, a result is placed into the corresponding target element as described in the following subsections. This result is the default result specified by Java, the IEEE standard, or C9X, as applicable.

Recall that denormalized source values are treated as if they were zero when $VSCR_{NJ}=1$. This has the following consequences regarding exceptions.

- Exceptions that can be caused by a zero source value can be caused by a denormalized source value when $VSCR_{NJ}=1$.
- Exceptions that can be caused by a nonzero source value cannot be caused by a denormalized source value when $VSCR_{NJ}=1$.

6.6.2.1 NaN Operand Exception

A NaN Operand Exception occurs when a source value for any of the following instructions is a NaN.

- A vector instruction that would normally produce floating-point results
- Either of the two *Vector Convert To Fixed-Point Word* instructions
- Any of the four *Vector Floating-Point Compare* instructions

The following actions are taken:

If the vector instruction would normally produce floating-point results, the corresponding result is a source NaN selected as follows. In all cases, if the selected source NaN is a Signaling NaN it is converted to the corresponding Quiet NaN (by setting the high-order bit of the fraction field to 1) before being placed into the target element.

```

if the element in VRA is a NaN
  then the result is that NaN
  else if the element in VRB is a NaN
    then the result is that NaN
    else if the element in VRC is a NaN
      then the result is that NaN
      else if Invalid Operation exception
        (Section 6.6.2.2)
        then the result is the QNaN 0x7FC0_0000
  
```

If the instruction is either of the two *Vector Convert To Fixed-Point Word* instructions, the corresponding result is 0x0000_0000. $VSCR_{SAT}$ is not affected.

If the instruction is *Vector Compare Bounds Floating-Point*, the corresponding result is 0xC000_0000.

If the instruction is one of the other *Vector Floating-Point Compare* instructions, the corresponding result is 0x0000_0000.

6.6.2.2 Invalid Operation Exception

An Invalid Operation Exception occurs when a source value or set of source values is invalid for the specified operation. The invalid operations are:

- Magnitude subtraction of infinities
- Multiplication of infinity by zero
- Reciprocal square root estimate of a negative, nonzero number or -infinity.
- Log base 2 estimate of a negative, nonzero number or -infinity.

The corresponding result is the QNaN 0x7FC0_0000.

6.6.2.3 Zero Divide Exception

A Zero Divide Exception occurs when a *Vector Reciprocal Estimate Floating-Point* or *Vector Reciprocal Square Root Estimate Floating-Point* instruction is executed with a source value of zero.

The corresponding result is an infinity, where the sign is the sign of the source value.

6.6.2.4 Log of Zero Exception

A Log of Zero Exception occurs when a *Vector Log Base 2 Estimate Floating-Point* instruction is executed with a source value of zero.

The corresponding result is -Infinity.

6.6.2.5 Overflow Exception

An Overflow Exception occurs under either of the following conditions.

- For a vector instruction that would normally produce floating-point results, the magnitude of what would have been the result if the exponent range were unbounded exceeds that of the largest finite floating-point number for the target floating-point format.
- For either of the two *Vector Convert To Fixed-Point Word* instructions, either a source value is an infinity or the product of a source value and 2^{UM} is a number too large in magnitude to be represented in the target fixed-point format.

The following actions are taken:

1. If the vector instruction would normally produce floating-point results, the corresponding result is an infinity, where the sign is the sign of the intermediate result.
2. If the instruction is *Vector Convert To Unsigned Fixed-Point Word Saturate*, the corresponding result is 0xFFFF_FFFF if the source value is a positive number or +infinity, and is 0x0000_0000 if the source value is a negative number or -infinity. $VSCR_{SAT}$ is set to 1.

3. If the instruction is *Vector Convert To Signed Fixed-Point Word Saturate*, the corresponding result is 0x7FFF_FFFF if the source value is a positive number or +infinity., and is 0x8000_0000 if the source value is a negative number or -infinity. VSCR_{SAT} is set to 1.

6.6.2.6 Underflow Exception

An Underflow Exception can occur only for vector instructions that would normally produce floating-point results. It is detected before rounding. It occurs when a nonzero intermediate result computed as though both the precision and the exponent range were unbounded is less in magnitude than the smallest normalized floating-point number for the target floating-point format.

The following actions are taken:

1. If VSCR_{NJ}=0, the corresponding result is the value produced by denormalizing and rounding the intermediate result.
2. If VSCR_{NJ}=1, the corresponding result is a zero, where the sign is the sign of the intermediate result.

6.7 Vector Storage Access Instructions

The Storage Access instructions compute the effective address (EA) of the storage to be accessed as described in Section 1.10.3, “Effective Address Calculation” on page 27. The low-order bits of the EA that would correspond to an unaligned storage operand are ignored.

The *Load Vector Element Indexed* and *Store Vector Element Indexed* instructions transfer a byte, halfword, or word element between storage and a Vector Register. The *Load Vector Indexed* and *Store Vector Indexed* instructions transfer an aligned quadword between storage and a Vector Register.

6.7.1 Storage Access Exceptions

Storage accesses will cause the system data storage error handler to be invoked if the program is not allowed to modify the target storage (*Store* only), or if the program attempts to access storage that is unavailable.

6.7.2 Vector Load Instructions

The aligned byte, halfword, word, or quadword in storage addressed by EA is loaded into register VRT.

Programming Note

The *Load Vector Element* instructions load the specified element into the same location in the target register as the location into which it would be loaded using the *Load Vector* instruction.

Load Vector Element Byte Indexed X-form

lvebx VRT,RA,RB

```
if RA = 0 then b ← 0
else b ← (RA)
EA ← b + (RB)
eb ← EA60:63
```

```
VRT ← undefined
if Big-Endian byte ordering then
    VRT8×eb:8×eb+7 ← MEM(EA,1)
else
    VRT120-(8×eb):127-(8×eb) ← MEM(EA,1)
```

Let the effective address (EA) be the sum (RAI0)+(RB).

Let eb be bits 60:63 of EA.

If Big-Endian byte ordering is used for the storage access, the contents of the byte in storage at address EA are placed into byte eb of register VRT. The remaining bytes in register VRT are set to undefined values.

If Category: Vector.Little-Endian is supported, then if Little-Endian byte ordering is used for the storage access, the contents of the byte in storage at address EA are placed into byte 15-eb of register VRT. The remaining bytes in register VRT are set to undefined values.

Special Registers Altered:

None

Load Vector Element Halfword Indexed X-form

lvehx VRT,RA,RB

```
if RA = 0 then b ← 0
else b ← (RA)
EA ← (b + (RB)) & 0xFFFF_FFFF_FFFF_FFFE
eb ← EA60:63
```

```
VRT ← undefined
if Big-Endian byte ordering then
    VRT8×eb:8×eb+15 ← MEM(EA,2)
else
    VRT112-(8×eb):127-(8×eb) ← MEM(EA,2)
```

Let the effective address (EA) be the result of ANDing 0xFFFF_FFFF_FFFF_FFFE with the sum (RAI0)+(RB).

Let eb be bits 60:63 of EA.

If Big-Endian byte ordering is used for the storage access,

- the contents of the byte in storage at address EA are placed into byte eb of register VRT,
- the contents of the byte in storage at address EA+1 are placed into byte eb+1 of register VRT, and
- the remaining bytes in register VRT are set to undefined values.

If Category: Vector.Little-Endian is supported, then if Little-Endian byte ordering is used for the storage access,

- the contents of the byte in storage at address EA are placed into byte 15-eb of register VRT,
- the contents of the byte in storage at address EA+1 are placed into byte 14-eb of register VRT, and
- the remaining bytes in register VRT are set to undefined values.

Special Registers Altered:

None

Load Vector Element Word Indexed
X-form

lvewx VRT,RA,RB

0	31	6	VRT	11	RA	16	RB	21	71	31
---	----	---	-----	----	----	----	----	----	----	----

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← (b + (RB)) & 0xFFFF_FFFF_FFFF_FFFC

```

```

eb ← EA60:63
VRT ← undefined
if Big-Endian byte ordering then
    VRT8×eb:8×eb+31 ← MEM(EA, 4)
else
    VRT96-(8×eb):127-(8×eb) ← MEM(EA, 4)

```

Let the effective address (EA) be the result of ANDing 0xFFFF_FFFF_FFFF_FFFC with the sum (RAI0)+(RB).

Let eb be bits 60:63 of EA.

If Big-Endian byte ordering is used for the storage access,

- the contents of the byte in storage at address EA are placed into byte eb of register VRT,
- the contents of the byte in storage at address EA+1 are placed into byte eb+1 of register VRT,
- the contents of the byte in storage at address EA+2 are placed into byte eb+2 of register VRT,
- the contents of the byte in storage at address EA+3 are placed into byte eb+3 of register VRT, and
- the remaining bytes in register VRT are set to undefined values.

If Category: Vector.Little-Endian is supported, then if Little-Endian byte ordering is used for the storage access,

- the contents of the byte in storage at address EA are placed into byte 15-eb of register VRT,
- the contents of the byte in storage at address EA+1 are placed into byte 14-eb of register VRT,
- the contents of the byte in storage at address EA+2 are placed into byte 13-eb of register VRT,
- the contents of the byte in storage at address EA+3 are placed into byte 12-eb of register VRT, and
- the remaining bytes in register VRT are set to undefined values.

Special Registers Altered:

None

Load Vector Indexed **X-form**

lvx VRT,RA,RB

0	31	6	VRT	11	RA	16	RB	21	103	31
---	----	---	-----	----	----	----	----	----	-----	----

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
VRT ← MEM(EA & 0xFFFF_FFFF_FFFF_FFF0, 16)

```

Let the effective address (EA) be the sum (RAI0)+(RB). The quadword in storage addressed by the result of EA ANDed with 0xFFFF_FFFF_FFFF_FFF0 is loaded into VRT.

Special Registers Altered:

None

Load Vector Indexed LRU **X-form**

lvxl VRT,RA,RB

0	31	6	VRT	11	RA	16	RB	21	359	31
---	----	---	-----	----	----	----	----	----	-----	----

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
VRT ← MEM(EA & 0xFFFF_FFFF_FFFF_FFF0, 16)
mark_as_not_likely_to_be_needed_again_anytime_soon
( EA )

```

Let the effective address (EA) be the sum (RAI0)+(RB). The quadword in storage addressed by the result of EA ANDed with 0xFFFF_FFFF_FFFF_FFF0 is loaded into VRT.

lvxl provides a hint that the quadword in storage addressed by EA will probably not be needed again by the program in the near future.

Special Registers Altered:

None

Programming Note

On some implementations, the hint provided by the *lvxl* instruction and the corresponding hint provided by the *stvxl*, *lvepxl*, and *stvepxl* instructions are applied to the entire cache block containing the specified quadword. On such implementations, the effect of the hint may be to cause that cache block to be considered a likely candidate for replacement when space is needed in the cache for a new block. Thus, on such implementations, the hint should be used with caution if the cache block containing the quadword also contains data that may be needed by the program in the near future. Also, the hint may be used before the last reference in a sequence of references to the quadword if the subsequent references are likely to occur sufficiently soon that the cache block containing the quadword is not likely to be displaced from the cache before the last reference.

6.7.3 Vector Store Instructions

Some portion or all of the contents of VRS are stored into the aligned byte, halfword, word, or quadword in storage addressed by EA.

Programming Note

The *Store Vector Element* instructions store the specified element into the same storage location as the location into which it would be stored using the *Store Vector* instruction.

Store Vector Element Byte Indexed X-form

stvebx VRS,RA,RB

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
eb ← EA60:63
if Big-Endian byte ordering then
    MEM(EA,1) ← VRS8×eb:8×eb+7
else
    MEM(EA,1) ← VRS120-(8×eb):127-(8×eb)

```

Let the effective address (EA) be the sum (RAI0)+(RB).

Let eb be bits 60:63 of EA.

If Big-Endian byte ordering is used for the storage access, the contents of byte eb of register VRS are placed in the byte in storage at address EA.

If Category: Vector.Little-Endian is supported, then if Little-Endian byte ordering is used for the storage access, the contents of byte 15-eb of register VRS are placed in the byte in storage at address EA.

Special Registers Altered:

None

Programming Note

Unless bits 60:63 of the address are known to match the byte offset of the subject byte element in register VRS, software should use *Vector Splat* to splat the subject byte element before performing the store.

Store Vector Element Halfword Indexed X-form

stvehx VRS,RA,RB

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← (b + (RB)) & 0xFFFF_FFFF_FFFF_FFFE
eb ← EA60:63
if Big-Endian byte ordering then
    MEM(EA,2) ← VRS8×eb:8×eb+15
else
    MEM(EA,2) ← VRS112-(8×eb):127-(8×eb)

```

Let the effective address (EA) be the result of ANDing 0xFFFF_FFFF_FFFF_FFFE with the sum (RAI0)+(RB).

Let eb be bits 60:63 of EA.

If Big-Endian byte ordering is used for the storage access,

- the contents of byte eb of register VRS are placed in the byte in storage at address EA, and
- the contents of byte eb+1 of register VRS are placed in the byte in storage at address EA+1.

If Category: Vector.Little-Endian is supported, then if Little-Endian byte ordering is used for the storage access,

- the contents of byte 15-eb of register VRS are placed in the byte in storage at address EA, and
- the contents of byte 14-eb of register VRS are placed in the byte in storage at address EA+1.

Special Registers Altered:

None

Programming Note

Unless bits 60:62 of the address are known to match the halfword offset of the subject halfword element in register VRS software should use *Vector Splat* to splat the subject halfword element before performing the store.

Store Vector Element Word Indexed X-form

stvevx VRS,RA,RB

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← (b + (RB)) & 0xFFFF_FFFF_FFFF_FFFC
eb ← EA60:63
if Big-Endian byte ordering then
    MEM(EA, 4) ← VRS8×eb:8×eb+31
else
    MEM(EA, 4) ← VRS96-(8×eb):127-(8×eb)

```

Let the effective address (EA) be the result of ANDing 0xFFFF_FFFF_FFFF_FFFC with the sum (RAI0)+(RB).

Let eb be bits 60:63 of EA.

If Big-Endian byte ordering is used for the storage access,

- the contents of byte eb of register VRS are placed in the byte in storage at address EA,
- the contents of byte eb+1 of register VRS are placed in the byte in storage at address EA+1,
- the contents of byte eb+2 of register VRS are placed in the byte in storage at address EA+2, and
- the contents of byte eb+3 of register VRS are placed in the byte in storage at address EA+3.

If Category: Vector.Little-Endian is supported, then if Little-Endian byte ordering is used for the storage access,

- the contents of byte 15-eb of register VRS are placed in the byte in storage at address EA,
- the contents of byte 14-eb of register VRS are placed in the byte in storage at address EA+1,
- the contents of byte 13-eb of register VRS are placed in the byte in storage at address EA+2, and
- the contents of byte 12-eb of register VRS are placed in the byte in storage at address EA+3.

Special Registers Altered:

None

Programming Note

Unless bits 60:61 of the address are known to match the word offset of the subject word element in register VRS, software should use *Vector Splat* to splat the subject word element before performing the store.

Store Vector Indexed X-form

stvx VRS,RA,RB

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
MEM(EA & 0xFFFF_FFFF_FFFF_FFF0, 16) ← (VRS)

```

Let the effective address (EA) be the sum (RAI0)+(RB). The contents of VRS are stored into the quadword in storage addressed by the result of EA ANDed with 0xFFFF_FFFF_FFFF_FFF0.

Special Registers Altered:

None

Store Vector Indexed LRU X-form

stvxI VRS,RA,RB

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
MEM(EA & 0xFFFF_FFFF_FFFF_FFF0, 16) ← (VRS)
mark_as_not_likely_to_be_needed_again_anytime_soon
(EA)

```

Let the effective address (EA) be the sum (RAI0)+(RB). The contents of VRS are stored into the quadword in storage addressed by the result of EA ANDed with 0xFFFF_FFFF_FFFF_FFF0.

stvxI provides a hint that the quadword in storage addressed by EA will probably not be needed again by the program in the near future.

Special Registers Altered:

None

Programming Note

See the Programming Note for the *lvxl* instruction on page 214.

6.7.4 Vector Alignment Support Instructions

Programming Note

The *lvsl* and *lvsr* instructions can be used to create the permute control vector to be used by a subsequent *vperm* instruction (see page 227). Let X and Y be the contents of register VRA and VRB specified by the *vperm*. The control vector created by *lvsl* causes the *vperm* to select the high-order 16 bytes of the result of shifting the 32-byte value X || Y left by sh bytes. The control vector created by *lvsr* causes the *vperm* to select the low-order 16 bytes of the result of shifting X || Y right by sh bytes.

Programming Note

Examples of uses of *lvsl*, *lvsr*, and *vperm* to load and store unaligned data are given in Section 6.4.1.

These instructions can also be used to rotate or shift the contents of a Vector Register left (*lvsl*) or right (*lvsr*) by sh bytes. For rotating, the Vector Register to be rotated should be specified as both register VRA and VRB for *vperm*. For shifting left, VRB for *vperm* should be a register containing all zeros and VRA should contain the value to be shifted, and vice versa for shifting right.

Load Vector for Shift Left Indexed X-form

```

Let the source vector be the concatenation of the contents of VRA followed by the contents of VRB.

For each vector element i from 0 to 7, do the following.

Word element i in the source vector is packed to produce a 16-bit value as described below.

- bit 7 of the first byte (bit 7 of the word)
- bits 0:4 of the second byte (bits 8:12 of the word)
- bits 0:4 of the third byte (bits 16:20 of the word)
- bits 0:4 of the fourth byte (bits 24:28 of the word)

The result is placed into halfword element i of VRT.

Special Registers Altered:

None

Programming Note

Each source word can be considered to be a 32-bit "pixel", consisting of four 8-bit "channels". Each target halfword can be considered to be a 16-bit pixel, consisting of one 1-bit channel and three 5-bit channels. A channel can be used to specify the intensity of a particular color, such as red, green, or blue, or to provide other information needed by the application.

Programming Note

The source and target elements can be considered to be 16-bit and 32-bit “pixels” respectively, having the formats described in the Programming Note for the *Vector Pack Pixel* instruction on page 219.

Programming Note

Notice that the unpacking done by the *Vector Unpack Pixel* instructions does not reverse the packing done by the *Vector Pack Pixel* instruction. Specifically, if a 16-bit pixel is unpacked to a 32-bit pixel which is then packed to a 16-bit pixel, the resulting 16-bit pixel will not, in general, be equal to the original 16-bit pixel (because, for each channel except the first, *Vector Unpack Pixel* inserts high-order bits while *Vector Pack Pixel* discards low-order bits).

0	6	11	16	21
31				

```
do i=0 to 127 by 16
  VRTi:i+15 ← EXTS(SIM, 16)
```

For each vector element i from 0 to 7, do the following.
The value of the SIM field, sign-extended to 16 bits, is placed into halfword element i of VRT.

Special Registers Altered:

None

Vector Splat Immediate Signed Word

VX-form

vspltswh VRT,SIM

4	VRT	SIM	///	908
0	6	11	16	21
31				

```
do i=0 to 127 by 32
  VRTi:i+31 ← EXTS(SIM, 32)
```

For each vector element i from 0 to 3, do the following.
The value of the SIM field, sign-extended to 32 bits, is placed into word element i of VRT.

Special Registers Altered:

None

6.8.4 Vector Permute Instruction

The *Vector Permute* instruction allows any byte in two source Vector Registers to be copied to any byte in the target Vector Register. The bytes in a third source Vector Register specify from which byte in the first two source Vector Registers the corresponding target byte is to be copied. The contents of the third source Vector Register are sometimes referred to as the “permute control vector”.

Vector Permute **VA-form**

vperm VRT,VRA,VRB,VRC

4	VRT	VRA	VRB	VRC	43
0	6	11	16	21	26
31					

```
temp0:255 ← (VRA) || (VRB)
do i=0 to 127 by 8
  b ← (VRC)i+3:i+7 || 0b000
  VRTi:i+7 ← tempb:b+7
```

Let the source vector be the concatenation of the contents of VRA followed by the contents of VRB.

For each vector element i from 0 to 15, do the following.

The contents of the byte element in the source vector specified by bits 3:7 of byte element i of VRC are placed into byte element i of VRT.

Special Registers Altered:

None

Programming Note

See the Programming Notes with the *Load Vector for Shift Left* and *Load Vector for Shift Right* instructions on page 218 for examples of uses of **vperm**.

6.8.5 Vector Select Instruction

Vector Select **VA-form**

vsel VRT,VRA,VRB,VRC

4	VRT	VRA	VRB	VRC	42
0	6	11	16	21	26
31					

do i=0 to 127

$VRT_i \leftarrow ((VRC)_i=0) ? (VRA)_i : (VRB)_i$

For each bit in VRC that contains the value 0, the corresponding bit in VRA is placed into the corresponding bit of VRT. Otherwise, the corresponding bit in VRB is placed into the corresponding bit of VRT.

Special Registers Altered:

None

6.8.6 Vector Shift Instructions

The *Vector Shift* instructions rotate or shift the contents of a Vector Register or a pair of Vector Registers left or right by a specified number of bytes (*vslo*, *vsro*, *vsldoi*) or bits (*vsl*, *vsr*). Depending on the instruction, this “shift count” is specified either by the contents of a Vector Register or by an immediate field in the instruction. In the former case, 7 bits of the shift count register give the shift count in bits ($0 \leq \text{count} \leq 127$). Of these 7 bits, the high-order 4 bits give the number of complete bytes by which to shift and are used by *vslo* and *vsro*; the low-order 3 bits give the number of remaining bits by which to shift and are used by *vsl* and *vsr*.

Programming Note

A pair of these instructions, specifying the same shift count register, can be used to shift the contents of a Vector Register left or right by the number of bits (0-127) specified in the shift count register. The following example shifts the contents of register Vx left by the number of bits specified in register Vy and places the result into register Vz.

```
vslo    Vz, Vx, Vy
vsl     Vz, Vz, Vy
```

Vector Shift Left

VX-form

vsl VRT,VRA,VRB

4	VRT	VRA	VRB	452
0	6	11	16	21
				31

```
sh ← (VRB)125:127
t ← 1
do i=0 to 127 by 8
    t ← t & ((VRB)i+5:i+7=sh)
if t=1 then VRT ← (VRA) << sh
else      VRT ← undefined
```

The contents of VRA are shifted left by the number of bits specified in (VRB)_{125:127}.

- Bits shifted out of bit 0 are lost.
- Zeros are supplied to the vacated bits on the right.

The result is placed into VRT, except if, for any byte element in register VRB, the low-order 3 bits are not equal to the shift amount, then VRT is undefined.

Special Registers Altered:

None

Vector Shift Left Double by Octet Immediate

VA-form

vsldoi VRT,VRA,VRB,SHB

4	VRT	VRA	VRB	SHB	44
0	6	11	16	21	26
					31

$$\text{VRT} \leftarrow ((\text{VRA}) \parallel (\text{VRB}))_{8 \times \text{SHB} : 8 \times \text{SHB} + 127}$$

Let the source vector be the concatenation of the contents of VRA followed by the contents of VRB. Bytes SHB:SHB+15 of the source vector are placed into VRT.

Special Registers Altered:

None

Vector Shift Left by Octet

VX-form

vslo VRT,VRA,VRB

4	VRT	VRA	VRB	1036
0	6	11	16	21
				31

```
shb ← (VRB)121:124
VRT ← (VRA) << ( shb || 0b000 )
```

The contents of VRA are shifted left by the number of bytes specified in (VRB)_{121:124}.

- Bytes shifted out of byte 0 are lost.
- Zeros are supplied to the vacated bytes on the right.

The result is placed into VRT.

Special Registers Altered:

None

Vector Shift Right**VX-form**

vsr VRT,VRA,VRB

	4	VRT	VRA	VRB	708	
0	6	11	16	21	31	

```
sh ← (VRB)125:127
t ← 1
do i=0 to 127 by 8
  t ← t & ((VRB)i+5:i+7=sh)
if t=1 then VRT ← (VRA) >>ui sh
else      VRT ← undefined
```

The contents of VRA are shifted right by the number of bits specified in (VRB)_{125:127}.

- Bits shifted out of bit 127 are lost.
- Zeros are supplied to the vacated bits on the left.

The result is placed into VRT, except if, for any byte element in register VRB, the low-order 3 bits are not equal to the shift amount, then VRT is undefined.

Special Registers Altered:

None

Programming Note

A double-register shift by a dynamically specified number of bits (0-127) can be performed in six instructions. The following example shifts Vw || Vx left by the number of bits specified in Vy and places the high-order 128 bits of the result into Vz.

```
vslo  Vt1,Vw,Vy  #shift high-order reg left
vs1   Vt1,Vt1,Vy
vsubum Vt3,V0,Vy #adjust shift count ((V0)=0)
vsro  Vt2,Vx,Vt3 #shift low-order reg right
vsr   Vt2,Vt2,Vt3
vor   Vz,Vt1,Vt2 #merge to get final result
```

Vector Shift Right by Octet**VX-form**

vsro VRT,VRA,VRB

	4	VRT	VRA	VRB	1100	
0	6	11	16	21	31	

```
shb ← (VRB)121:124
VRT ← (VRA) >>ui ( shb || 0b000 )
```

The contents of VRA are shifted right by the number of bytes specified in (VRB)_{121:124}.

- Bytes shifted out of byte 15 are lost.
- Zeros are supplied to the vacated bytes on the left.

The result is placed into VRT.

Special Registers Altered:

6.9.2 Vector Integer Compare Instructions

The *Vector Integer Compare* instructions compare two Vector Registers element by element, interpreting the elements as unsigned or signed-integers depending on the instruction, and set the corresponding element of the target Vector Register to all 1s if the relation being tested is true and to all 0s if the relation being tested is false.

If Rc=1 CR Field 6 is set to reflect the result of the comparison, as follows.

Bit	Description
0	The relation is true for all element pairs (i.e., VRT is set to all 1s)
1	0
2	The relation is false for all element pairs (i.e., VRT is set to all 0s)
3	0

Programming Note

vcmpaqub[], *vcmpaquh*[] and *vcmpaquw*[] can be used for unsigned or signed-integers.

Vector Compare Equal To Unsigned Byte VC-form

vcmpaqub VRT,VRA,VRB (Rc=0)

6.9.3 Vector Logical Instructions

Extended mnemonics for vector logical operations

Extended mnemonics are provided that use the Vector OR and Vector NOR instructions to copy the contents of one Vector Register to another, with and without complementing. These are shown as examples with the two instructions.

Vector Move Register

Several vector instructions can be coded in a way such that they simply copy the contents of one Vector Register to another. An extended mnemonic is provided to convey the idea that no computation is being performed but merely data movement (from one register to another).

The following instruction copies the contents of register Vy to register Vx.

`vmr Vx,Vy` (equivalent to: `vor Vx,Vy,Vy`)

Vector Complement Register

The *Vector NOR* instruction can be coded in a way such that it complements the contents of one Vector Register and places the result into another Vector Register. An extended mnemonic is provided that allows this operation to be coded easily.

The following instruction complements the contents of register Vy and places the result into register Vx.

`vnot Vx,Vy` (equivalent to: `vnor Vx,Vy,Vy`)

Vector Logical AND VX-form

`vand` VRT,VRA,VRB

0	4	VRT	VRA	VRB	1028	31
		6	11	16	21	

$VRT \leftarrow (VRA) \& (VRB)$

The contents of VRA are ANDed with the contents of VRB and the result is placed into VRT.

Special Registers Altered:
None

Vector Logical AND with Complement VX-form

`vandc` VRT,VRA,VRB

0	4	VRT	VRA	VRB	1092	31
		6	11	16	21	

$VRT \leftarrow (VRA) \& \neg(VRB)$

The contents of VRA are ANDed with the complement of the contents of VRB and the result is placed into VRT.

Special Registers Altered:
None

Vector Logical NOR VX-form

`vnor` VRT,VRA,VRB

0	4	VRT	VRA	VRB	1284	31
		6	11	16	21	

$VRT \leftarrow \neg((VRA) | (VRB))$

The contents of VRA are ORed with the contents of VRB and the complemented result is placed into VRT.

Special Registers Altered:
None

Vector Logical OR VX-form

`vor` VRT,VRA,VRB

0	4	VRT	VRA	VRB	1156	31
		6	11	16	21	

$VRT \leftarrow (VRA) | (VRB)$

The contents of VRA are ORed with the contents of VRB and the result is placed into VRT.

Special Registers Altered:
None

Vector Logical XOR VX-form

`vxor` VRT,VRA,VRB

0	4	VRT	VRA	VRB	1220	31
		6	11	16	21	

$VRT \leftarrow (VRA) \oplus (VRB)$

The contents of VRA are XORed with the contents of VRB and the result is placed into VRT.

Special Registers Altered:
None

6.9.4 Vector Integer Rotate and Shift Instructions

Vector Rotate Left Byte

VX-form

vrlb VRT,VRA,VRB

```
do i=0 to 127 by 8
  sh ← (VRB)i+5:i+7
  VRTi:i+7 ← (VRA)i:i+7 <<< sh
```

For each vector element i from 0 to 15, do the following.

Byte element i in VRA is rotated left by the number of bits specified in the low-order 3 bits of the corresponding byte element i in VRB.

The result is placed into byte element i in VRT.

Special Registers Altered:

None

Vector Rotate Left Word

VX-form

vrlw VRT,VRA,VRB

```
do i=0 to 127 by 32
  sh ← (VRB)i+27:i+31
  VRTi:i+31 ← (VRA)i:i+31 <<< sh
```

For each vector element i from 0 to 3, do the following.

Word element i in VRA is rotated left by the number of bits specified in the low-order 5 bits of the corresponding word element i in VRB.

The result is placed into word element i in VRT.

Special Registers Altered:

None

Vector Rotate Left Halfword

VX-form

vrlh VRT,VRA,VRB

```
do i=0 to 127 by 16
  sh ← (VRB)i+12:i+15
  VRTi:i+15 ← (VRA)i:i+15 <<< sh
```

For each vector element i from 0 to 7, do the following.

Halfword element i in VRA is rotated left by the number of bits specified in the low-order 4 bits of the corresponding halfword element i in VRB.

The result is placed into halfword element i in VRT.

Special Registers Altered:

```
do i=0 to 127 by 32
  prod ← (VRA)i:i+31 ×fp (VRC)i:i+31
  VRTi:i+31 ← RoundToNearSP( prod +fp (VRB)i:i+31 )
```

For each vector element i from 0 to 3, do the following.

Single-precision floating-point element i in VRA is multiplied by single-precision floating-point element i in VRC. Single-precision floating-point element i in VRB is added to the infinitely-precise product. The intermediate result is rounded to the nearest single-precision floating-point number and placed into word element i of VRT.

Special Registers Altered:

None

Programming Note

To use a multiply-add to perform an IEEE or Java compliant multiply, the addend must be -0.0. This is necessary to insure that the sign of a zero result will be correct when the product is -0.0 ($+0.0 + -0.0 \geq +0.0$, and $-0.0 + -0.0 \geq -0.0$). When the sign of a resulting 0.0 is not important, then +0.0 can be used as an addend which may, in some cases, avoid the need for a second register to hold a -0.0 in addition to the integer 0/floating-point +0.0 that may already be available.

Vector Negative Multiply-Subtract Single-Precision VA-form

vnmsubfp VRT,VRA,VRC,VRB

4	VRT	VRA	VRB	VRC	47
0	6	11	16	21	26 31

```
do i=0 to 127 by 32

Single-precision floating-point element i in VRB is rounded to a single-precision floating-point integer using the rounding mode Round toward Zero.

The result is placed into the corresponding word element i of VRT.

Special Registers Altered:

None

6.10.4 Vector Floating-Point Compare Instructions

The *Vector Floating-Point Compare* instructions compare two Vector Registers word element by word element, interpreting the elements as single-precision floating-point numbers. With the exception of the *Vector Compare Bounds Floating-Point* instruction, they set the target Vector Register, and CR Field 6 if Rc=1, in the same manner as do the *Vector Integer Compare* instructions; see Section 6.9.2.

The *Vector Compare Bounds Floating-Point* instruction sets the target Vector Register, and CR Field 6 if Rc=1, to indicate whether the elements in VRA are within the bounds specified by the corresponding element in VRB, as explained in the instruction description. A single-precision floating-point value x is said to be “within the bounds” specified by a single-precision floating-point value y if $-y \leq x \leq y$.

Vector Compare Bounds Single-Precision VC-form

vcmpbfp VRT,VRA,VRB (Rc=0)
vcmpbfp VRT,VRA,VRB (Rc=1)

4	VRT	VRA	VRB	Rc	966
0	6	11	16	21 22	31

```
do i=0 to 127 by 32
  le ← ( (VRA)i:i+31 ≤fp (VRB)i:i+31 )
  ge ← ( (VRA)i:i+31 ≥fp -(VRB)i:i+31 )
  VRTi:i+31 ← ¬le || ¬ge || 300
if Rc=1 then do
  ib ← (VRT=1280)
  CR6 ← 0b00 || ib || 0b0
```

For each vector element i from 0 to 3, do the following.

Single-precision floating-point word element i in VRA is compared to single-precision floating-point word element i in VRB. A 2-bit value is formed that indicates whether the element in VRA is within the bounds specified by the element in VRB, as follows.

- Bit 0 of the 2-bit value is set to 0 if the element in VRA is less than or equal to the element in VRB, and is set to 1 otherwise.
- Bit 1 of the 2-bit value is set to 0 if the element in VRA is greater than or equal to the negation of the element in VRB, and is set to 1 otherwise.

The 2-bit value is placed into the high-order two bits of word element i of VRT and the remaining bits of element i are set to 0.

If Rc=1, CR field 6 is set as follows.

Bit Description

- | | |
|---|---|
| 0 | Set to 0 |
| 1 | Set to 0 |
| 2 | Set to indicate whether all four elements in VRA are within the bounds specified by the corresponding element in VRB, otherwise set to 0. |
| 3 | Set to 0 |

Special Registers Altered:

CR6 (if Rc=1)

Programming Note

Each single-precision floating-point word element in VRB should be non-negative; if it is negative, the corresponding element in VRA will necessarily be out of bounds.

One exception to this is when the value of an element in VRB is -0.0 and the value of the corresponding element in VRA is either +0.0 or -0.0. +0.0 and -0.0 compare equal to -0.0.

Vector Compare Equal To Single-Precision VC-form

vcmppeqfp VRT,VRA,VRB (Rc=0)
vcmppeqfp VRT,VRA,VRB (Rc=1)

4	VRT	VRA	VRB	Rc	198
0	6	11	16	21 22	31

do i=0 to 127 by 32

$VRT_{i:i+31} \leftarrow \text{LogBase2EstimateSP}((VRB)_{i:i+31})$

For each vector element i from 0 to 3, do the following.

The single-precision floating-point estimate of the base 2 logarithm of single-precision floating-point element i in VRB is placed into the corresponding word element of VRT.

Let x be any single-precision floating-point input value. Unless $|x-1|$ is less than or equal to 0.125 or the single-precision floating-point result of computing the base 2 logarithm of x would be an infinity or a QNaN, the estimate has an absolute error in precision (absolute value of the difference between the estimate and the infinitely precise value) no greater than 2^{-5} . Under the same conditions, the estimate has a relative error in precision no greater than one part in 8.

The most significant 12 bits of the estimate's significand are monotonic. The estimate is exact if $x=2^y$, where y is an integer between -149 and +127 inclusive. Otherwise the value placed into the element of register VRT may vary between implementations, and between different executions on the same implementation.

The result for various special cases of the source value is given below.

Value	Result
- Infinity	QNaN
< 0	QNaN
- 0	- Infinity
+0	- Infinity
+Infinity	+Infinity
NaN	QNaN

Special Registers Altered:

7.1 Introduction

7.1.1 Overview of the Vector-Scalar Extension

Category Vector-Scalar Extension (VSX) provides facilities supporting vector and scalar binary floating-point operations. The following VSX features are provided to increase opportunities for vectorization.

- A unified register file, a set of Vector-Scalar Registers (VSR), supporting both scalar and vector operations is provided, eliminating the overhead of vector-scalar data transfer through storage.
- Support for word-aligned storage accesses for both scalar and vector operations is provided.
- Robust support for IEEE-754 for both vector and scalar floating-point operations is provided.

Combining the Floating-Point Registers (FPR) defined in Chapter 4. Floating-Point Facility [Category: Floating-Point] and the Vector Registers (VR) defined in Chapter 6. Vector Facility [Category: Vector] provides additional registers to support more aggressive compiler optimizations for both vector and scalar operations.

Implementations of VSX must also implement the Floating-Point (Chapter 4) and Vector (Chapter 6) categories.

7.1.1.1 Compatibility with Category Floating-Point and Category Decimal Floating-Point Operations

The instruction sets defined in Chapter 4. Floating-Point Facility [Category: Floating-Point] and Chapter 5. Decimal Floating-Point [Category: Decimal Floating-Point] retain their definition with one primary difference. The FPRs are mapped to doubleword element 0 of VSRs 0-31. The contents of doubleword 1 of the VSR corresponding to a source FPR specified by an instruction are ignored. The contents of doubleword 1 of a VSR corresponding to the target FPR specified by an instruction are undefined.

Programming Note

Application binary interfaces extended to support VSX require special care of vector data written to VSRs 0-31 (i.e., VSRs corresponding to FPRs). Legacy scalar function calls employ doubleword-based loads and stores to preserve the contents of any nonvolatile registers. This has the adverse effect of not preserving the contents of doubleword 1 of these VSRs.

7.1.1.2 Compatibility with Category Vector Operations

The instruction set defined in Chapter 6. Vector Facility [Category: Vector], retains its definition with one primary difference. The VRs are mapped to VSRs 32-63.

7.2 VSX Registers

7.2.1 Vector-Scalar Registers

Sixty-four 128-bit VSRs are provided. See Figure 106 All VSX floating-point computations and other data manipulation are performed on data residing in Vector-Scalar Registers, and results are placed into a VSR.

Depending on the instruction, the contents of a VSR are interpreted as a sequence of equal-length elements (words or doublewords) or as a quadword. Each of the elements is aligned at its natural boundary within the VSR, as shown in Figure 106. Many instructions perform a given operation in parallel on all elements in a VSR. Depending on the instruction, a word element can be interpreted as a signed integer word (SW), an unsigned integer word (UW), a logical mask value (MW), or a single-precision floating-point value (SP); a doubleword element can be interpreted as a doubleword signed integer (SD), a doubleword unsigned integer (UD), a doubleword mask (DM), or a double-precision floating-point value (DP). In the instructions descriptions, phrases like *signed integer word element* are used as shorthand for *word element, interpreted as a signed integer*.

Load and Store instructions are provided that transfer a byte, halfword, word, doubleword, or quadword between storage and a VSR.

Figure 106.Vector-Scalar Registers

Figure 107.Vector-Scalar Register Elements

7.2.1.1 Floating-Point Registers

Chapter 4. Floating-Point Facility [Category: Floating-Point] provides 32 64-bit FPRs. Chapter 5. Decimal Floating-Point [Category: Decimal Floating-Point] also employs FPRs in decimal floating-point (DFP) operations. When VSX is implemented, the 32 FPRs are mapped to doubleword 0 of VSRs 0-31. For example, FPR[0] is located in

doubleword element 0 of VSR[0], FPR[1] is located in doubleword element 0 of VSR[1], and so forth.

All instructions that operate on an FPR are redefined to operate on doubleword element 0 of the corresponding VSR. The contents of doubleword element 1 of the VSR corresponding to a source FPR or FPR pair for these instructions are ignored and the contents of doubleword element 1 of the VSR corresponding to the target FPR or FPR pair for these instructions are undefined.

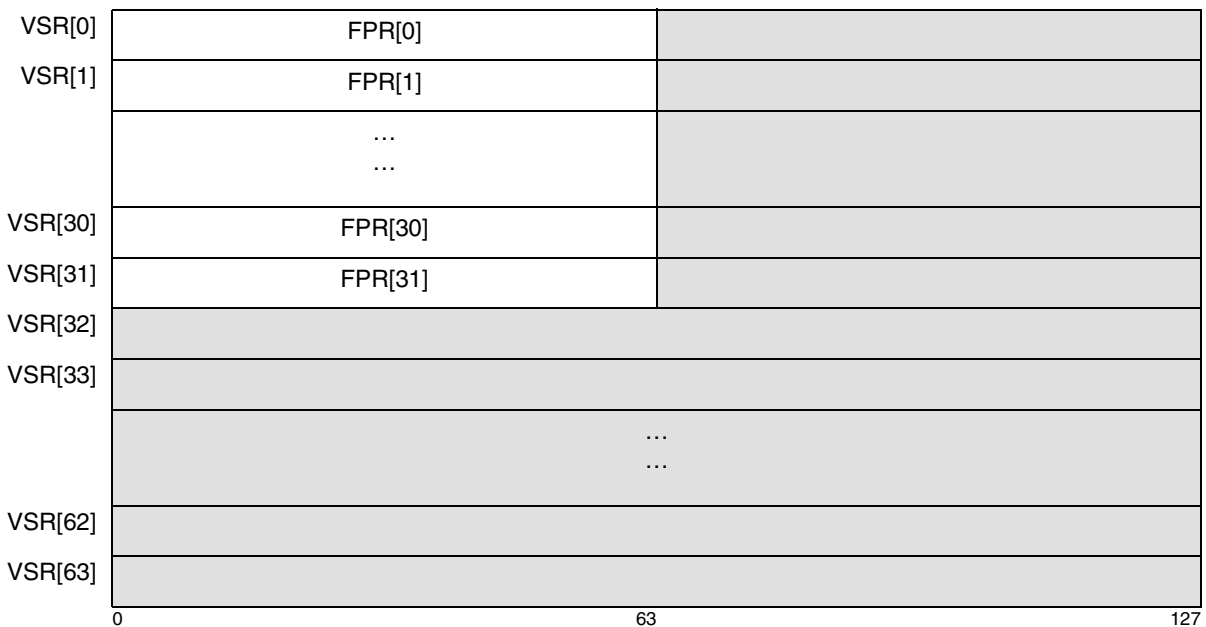

Figure 108.Floating-Point Registers as part of VSRs

7.2.1.2 Vector Registers

Chapter 6. Vector Facility [Category: Vector] provides 32 128-bit VRs. When VSX is implemented, the 32 VRs are mapped to VSRs 32-63. For example, VR[0] is located in VSR[32], VR[1] is located in VSR[33], and so forth.

All instructions that operate on a VR are redefined to operate on the corresponding VSR.

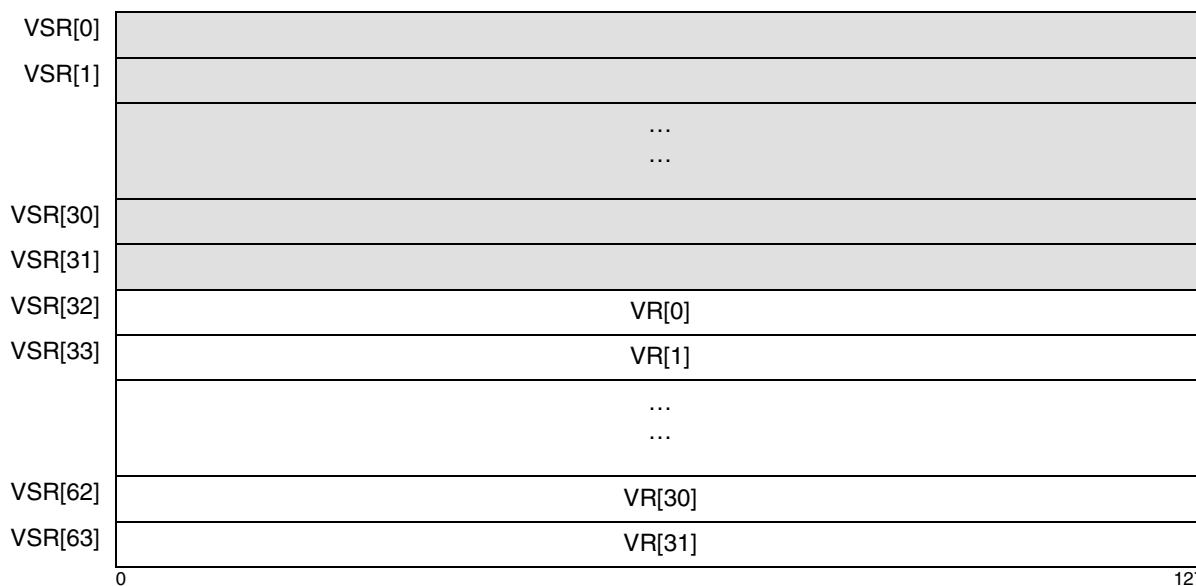

Figure 109. Vector Registers as part of VSRs

7.2.2 Floating-Point Status and Control Register

The Floating-Point Status and Control Register (FPSCR) controls the handling of floating-point exceptions and records status resulting from the floating-point operations. Bits 0:19 and 32:55 are status bits. Bits 56:63 are control bits.

The exception status bits in the FPSCR (bits 35:44, 53:55) are sticky; that is, once set to 1 they remain set to 1 until they are set to 0 by an *mcrfs*, *mtfsfi*, *mtfsf*, or *mtfsb0* instruction. The exception summary bits in the FPSCR (FX, FEX, and VX, which are bits 32:34) are not considered to be “exception status bits”, and only FX is sticky.

Programming Note

Access to *Move To FPSCR* and *Move From FPSCR* instructions requires FP=1.

FEX and VX are simply the ORs of other FPSCR bits. Therefore these two bits are not listed among the FPSCR bits affected by the various instructions.

The bit definitions for the FPSCR are as follows.

Bits Definition

0:28 **Decimal Floating-Point Rounding Control (DRN)**
This field is not used by VSX instructions.

32 **Floating-Point Exception Summary (FX)**
Every floating-point instruction, except *mtfsfi* and *mtfsf*, implicitly sets FX to 1 if that instruction causes any of the floating-point exception bits in the FPSCR to change from 0 to 1. *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, and *mtfsb1* can alter FX explicitly.

Programming Note

FX is defined not to be altered implicitly by *mtfsfi* and *mtfsf* because permitting these instructions to alter FX implicitly can cause a paradox. An example is an *mtfsfi* or *mtfsf* instruction that supplies 0 for FX and 1 for OX, and is executed when OX=0. See also the Programming Notes with the definition of these two instructions.

33 **Floating-Point Enabled Exception Summary (FEX)**
This bit is the OR of all the floating-point exception bits masked by their respective enable bits. *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, and *mtfsb1* cannot alter FEX explicitly.

Bits	Definition
34	<p>Floating-Point Invalid Operation Exception Summary (VX) This bit is the OR of all the Invalid Operation exception bits. <i>mcrfs</i>, <i>mtfsfi</i>, <i>mtfsf</i>, <i>mtfsb0</i>, and <i>mtfsb1</i> cannot alter VX explicitly.</p>
35	<p>Floating-Point Overflow Exception (OX) This bit is set to 1 when a <i>VSX Scalar Floating-Point Arithmetic</i>, <i>VSX Vector Floating-Point Arithmetic</i>, <i>VSX Scalar DP-SP Conversion</i> or <i>VSX Vector DP-SP Conversion</i> class instruction causes an Overflow exception. See Section 7.4.3 , “Floating-Point Overflow Exception” on page 304. This bit can be set to 0 or 1 by a <i>Move To FPSCR</i> class instruction.</p>
36	<p>Floating-Point Underflow Exception (UX) This bit is set to 1 when a <i>VSX Scalar Floating-Point Arithmetic</i>, <i>VSX Vector Floating-Point Arithmetic</i>, <i>VSX Scalar DP-SP Conversion</i> or <i>VSX Vector DP-SP Conversion</i> class instruction causes an Underflow exception. See Section 7.4.4 , “Floating-Point Underflow Exception” on page 306. This bit can be set to 0 or 1 by a <i>Move To FPSCR</i> class instruction.</p>
37	<p>Floating-Point Zero Divide Exception (ZX) This bit is set to 1 when a <i>VSX Scalar Floating-Point Arithmetic</i> or <i>VSX Vector Floating-Point Arithmetic</i> class instruction causes a Zero Divide exception. See Section 7.4.2 , “Floating-Point Zero Divide Exception” on page 302. This bit can be set to 0 or 1 by a <i>Move To FPSCR</i> class instruction.</p>
38	<p>Floating-Point Inexact Exception (XX) This bit is set to 1 when a <i>VSX Scalar Floating-Point Arithmetic</i>, <i>VSX Vector Floating-Point Arithmetic</i>, <i>VSX Scalar Integer Conversion</i>, <i>VSX Vector Integer Conversion</i>, <i>VSX Scalar Round to Floating-Point Integer</i>, or <i>VSX Vector Round to Floating-Point Integer</i> class instruction causes an Inexact exception. See Section 7.4.5 , “Floating-Point Inexact Exception” on page 308. This bit can be set to 0 or 1 by a <i>Move To FPSCR</i> class instruction.</p>

Bits	Definition	Bits	Definition
39	<p>Floating-Point Invalid Operation Exception (SNAN) (VXSNaN)</p> <p>This bit is set to 1 when a <i>VSX Scalar Floating-Point</i> and <i>VSX Vector Floating-Point</i> class instruction causes an SNaN type Invalid Operation exception. See Section 7.3.2.6 on page 287. This bit is not sticky.</p> <p>See the definition of XX, above, regarding the relationship between FI and XX.</p>

Bits Definition

47:51 **Floating-Point Result Flags (FPRF)**
VSX Scalar Floating-Point Arithmetic, VSX Scalar DP-SP Conversion, VSX Scalar Convert Integer to Double-Precision, and VSX Scalar Round to Double-Precision Integer class instructions set this field based on the result placed into the target register and on the target precision, except that if any portion of the result is undefined then the value placed into FPRF is undefined.

For *VSX Scalar Convert Double-Precision to Integer* class instructions, the value placed into FPRF is undefined.

Additional details are as follows.

47 **Floating-Point Result Class Descriptor (C)**
VSX Scalar Floating-Point Arithmetic, VSX Scalar DP-SP Conversion, VSX Scalar Convert Integer to Double-Precision, and VSX Scalar Round to Double-Precision Integer class instructions set this bit with the FPCC bits, to indicate the class of the result as shown in Table 2, “Floating-Point Result Flags,” on page 281.

48:51 **Floating-Point Condition Code (FPCC)**
VSX Scalar Compare Double-Precision instruction sets one of the FPCC bits to 1 and the other three FPCC bits to 0 based on the relative values of the operands being compared.

VSX Scalar Floating-Point Arithmetic, VSX Scalar DP-SP Conversion, VSX Scalar Convert Integer to Double-Precision, and VSX Scalar Round to Double-Precision Integer class instructions set the FPCC bits with the C bit, to indicate the class of the result as shown in Table 2, “Floating-Point Result Flags,” on page 281. Note that in this case the high-order three bits of the FPCC retain their relational significance indicating that the value is less than, greater than, or equal to zero.

Bits Definition

48 **Floating-Point Less Than or Negative (FL)**

49 **Floating-Point Greater Than or Positive (FG)**

50 **Floating-Point Equal or Zero (FE)**

51 **Floating-Point Unordered or NaN (FU)**

52 Reserved

53 **Floating-Point Invalid Operation Exception (Software-Defined Condition) (VXSOF)**
 This bit can be altered only by *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, or *mtfsb1*. See Section 7.4.1, “Floating-Point Invalid Operation Exception” on page 295.

Programming Note

VXSOF can be used by software to indicate the occurrence of an arbitrary, software-defined, condition that is to be treated as an Invalid Operation exception. For example, the bit could be set by a program that computes a base 10 logarithm if the supplied input is negative.

54 **Floating-Point Invalid Operation Exception (Invalid Square Root) (VXSQRT)**

This bit is set to 1 when a *VSX Scalar Floating-Point Arithmetic* or *VSX Vector Floating-Point Arithmetic* class instruction causes a Invalid Square Root type Invalid Operation exception. See Section 7.4.1, “Floating-Point Invalid Operation Exception” on page 295.

This bit can be set to 0 or 1 by a *Move To FPSCR* class instruction.

55 **Floating-Point Invalid Operation Exception (Invalid Integer Convert) (VXCVI)**

This bit is set to 1 when a *VSX Scalar Convert Double-Precision to Integer*, *VSX Vector Convert Double-Precision to Integer*, or *VSX Vector Convert Single-Precision to Integer* class instruction causes a Invalid Integer Convert type Invalid Operation exception. See Section 7.4.1, “Floating-Point Invalid Operation Exception” on page 295.

This bit can be set to 0 or 1 by a *Move To FPSCR* class instruction.

Bits	Definition	
56	<p>Floating-Point Invalid Operation Exception Enable (VE) This bit is used by <i>VSX Scalar Floating-Point</i> and <i>VSX Vector Floating-Point</i> class instructions to enable trapping on Invalid Operation exceptions. See Section 7.4.1 , “Floating-Point Invalid Operation Exception” on page 295.</p>	<p>0 The processor is not in floating-point non-IEEE mode (i.e., all floating-point operations conform to the IEEE standard).</p> <p>1 The processor is in floating-point non-IEEE mode.</p>
57	<p>Floating-Point Overflow Exception Enable (OE) This bit is used by <i>VSX Scalar Floating-Point</i> and <i>VSX Vector Floating-Point</i> class instructions to enable trapping on Overflow exceptions. See Section 7.4.3 , “Floating-Point Overflow Exception” on page 304.</p>	
58	<p>Floating-Point Underflow Exception Enable (UE) This bit is used by <i>VSX Scalar Floating-Point</i> and <i>VSX Vector Floating-Point</i> class instructions to enable trapping on Underflow exceptions. See Section 7.4.4 , “Floating-Point Underflow Exception” on page 306.</p>	
59	<p>Floating-Point Zero Divide Exception Enable (ZE) This bit is used by <i>VSX Scalar Floating-Point</i> and <i>VSX Vector Floating-Point</i> class instructions to enable trapping on Zero Divide exceptions. See Section 7.4.2 , “Floating-Point Zero Divide Exception” on page 302.</p>	
60	<p>Floating-Point Inexact Exception Enable (XE) This bit is used by <i>VSX Scalar Floating-Point</i> and <i>VSX Vector Floating-Point</i> class instructions to enable trapping on Inexact exceptions. See Section 7.4.5 , “Floating-Point Inexact Exception” on page 308.</p>	
61	<p>Floating-Point Non-IEEE Mode (NI) Floating-point non-IEEE mode is optional. If floating-point non-IEEE mode is not implemented, this bit is treated as reserved, and the remainder of the definition of this bit does not apply.</p> <p>If floating-point non-IEEE mode is implemented, this bit has the following meaning.</p>	

Bits	Definition
61	Floating-Point Non-IEEE Mode (NI) (continued)

When the processor is in floating-point non-IEEE mode, the remaining FPSCR bits is permitted to have meanings different from those given in this document, and floating-point operations need not conform to the IEEE standard. The effects of executing a given floating-point instruction with NI=1, and any additional requirements for using non-IEEE mode, are implementation-dependent. The results of executing a given instruction in non-IEEE mode is permitted to vary between implementations, and between different executions on the same implementation.

Programming Note

When the processor is in floating-point non-IEEE mode, the results of floating-point operations is permitted to be approximate, and performance for these operations might be better, more predictable, or less data-dependent than when the processor is not in non-IEEE mode. For example, in non-IEEE mode an implementation is permitted to return 0 instead of a denormalized number and return a large number instead of an infinity.

62:63	Floating-Point Rounding Control (RN)
-------	---

This field is used by *VSX Scalar Floating-Point* and *VSX Vector Floating-Point* class instructions that round their result and the rounding mode is not implied by the opcode.

This bit can be explicitly set or reset by a new Move To FPSCR class instruction.

See Section 7.3.2.6 , “Rounding” on page 287.

- 00 Round to Nearest Even
- 01 Round toward Zero
- 10 Round toward +Infinity
- 11 Round toward -Infinity

Result Flags					Result Value Class
C	FL	FG	FE	FU	
1	0	0	0	1	Quiet NaN
0	1	0	0	1	- Infinity
0	1	0	0	0	- Normalized Number
1	1	0	0	0	- Denormalized Number
1	0	0	1	0	- Zero
0	0	0	1	0	+ Zero
1	0	1	0	0	+ Denormalized Number
0	0	1	0	0	+ Normalized Number
0	0	1	0	1	+ Infinity

Table 2. Floating-Point Result Flags

7.3 VSX Operations

7.3.1 VSX Floating-Point Arithmetic Overview

This section describes the floating-point arithmetic and exception model supported by category Vector-Scalar Extension. Except for extensions to support 32-bit single-precision floating-point vector operations, the models are identical to that described in Chapter 4. Floating-Point Facility [Category: Floating-Point].

The processor (augmented by appropriate software support, where required) implements a floating-point system compliant with the ANSI/IEEE Standard 754-1985, *IEEE Standard for Binary Floating-Point Arithmetic* (hereafter referred to as *the IEEE standard*). That standard defines certain required "operations" (addition, subtraction, and so on). Herein, the term, floating-point operation, is used to refer to one of these required operations and to additional operations defined (e.g., those performed by *Multiply-Add* or *Reciprocal Estimate* instructions). A Non-IEEE mode is also provided. This mode, which is permitted to produce results not in strict compliance with the IEEE standard, allows shorter latency.

Instructions are provided to perform arithmetic, rounding, conversion, comparison, and other operations in VSRs; to move floating-point data between storage and these registers.

These instructions are divided into two categories.

- computational instructions

The computational instructions are those that perform addition, subtraction, multiplication, division, extracting the square root, rounding, conversion, comparison, and combinations of these operations. These instructions provide the floating-point operations. There are two forms of computational instructions, scalar, which perform a single floating-point operation, and vector, which perform either two double-precision floating-point operations or four single-precision operations. Computational instructions place status information into the Floating-Point Status and Control Register. They are the instructions described in Sections 7.6.3 through 7.6.7.2.

- noncomputational instructions

The noncomputational instructions are those that perform loads and stores, move the contents of a VSR to another floating-point register possibly altering the sign, and select the value from one of two VSRs based on the value in a third VSR. The operations performed by these instructions are not considered floating-point operations. These instructions do not alter the Floating-Point Status and Control Register. They are the instructions

listed in Sections 7.6.1, 7.6.2.1, and 7.6.8 through 7.6.9.

A floating-point number consists of a signed exponent and a signed significand. The quantity expressed by this number is the product of the significand and the number 2^{exponent} . Encodings are provided in the data format to represent finite numeric values, \pm Infinity, and values that are "Not a Number" (NaN). Operations involving infinities produce results obeying traditional mathematical conventions. NaNs have no mathematical interpretation. Their encoding permits a variable diagnostic information field. NaNs might be used to indicate such things as uninitialized variables and can be produced by certain invalid operations.

There is one class of exceptional events that occur during instruction execution that is unique to categories Vector-Scalar Extension and Floating-Point: the Floating-Point Exception. Floating-point exceptions are signaled with bits set in the FPSCR. They can cause the system floating-point enabled exception error handler to be invoked, precisely or imprecisely, if the proper control bits are set.

Floating-Point Exceptions

The following floating-point exceptions are detected by the processor:

- | | |
|-------------------------------|----------|
| – Invalid Operation exception | (VX) |
| SNaN | (VXSNAN) |
| Infinity–Infinity | (VXISI) |
| Infinity÷Infinity | (VXIDI) |
| Zero÷Zero | (VXZDZ) |
| Infinity×Zero | (VXIMZ) |
| Invalid Compare | (VXVC) |
| Software-Defined Condition | (VXSOFT) |
| Invalid Square Root | (VXSQRT) |
| Invalid Integer Convert | (VXCVI) |
| – Zero Divide exception | (ZX) |
| – Overflow exception | (OX) |
| – Underflow exception | (UX) |
| – Inexact exception | (XX) |

Each floating-point exception, and each category of Invalid Operation exception, has an exception bit in the FPSCR. In addition, each floating-point exception has a corresponding enable bit in the FPSCR. See Section 7.2.2, "Floating-Point Status and Control Register" on page 276 for a description of these exception and enable bits, and Section 7.3.3, "VSX Floating-Point Execution Models" on page 289 for a detailed discussion of floating-point exceptions, including the effects of the enable bits.

7.3.2 VSX Floating-Point Data

7.3.2.1 Data Format

This architecture defines the representation of a floating-point value in two different binary fixed-length formats, 32-bit single-precision format and 64-bit double-precision format. The single-precision format is used for SP data in storage and registers. The double-precision format is used for DP data in storage and registers.

The lengths of the exponent and the fraction fields differ between these two formats. The structure of the single-precision and double-precision formats is shown below.

Values in floating-point format are composed of three fields:

S sign bit
 EXP exponent+bias
 FRACTION fraction

Representation of numeric values in the floating-point formats consists of a sign bit (S), a biased exponent (EXP), and the fraction portion (FRACTION) of the significand. The significand consists of a leading implied bit concatenated on the right with the FRACTION. This leading implied bit is 1 for normalized numbers and 0 for denormalized numbers and is located in the unit bit position (that is, the first bit to the left of the binary point). Values representable within the two floating-point formats can be specified by the parameters listed in Table 3.

Figure 110. Floating-point single-precision format

Figure 111. Floating-point double-precision format

	Single-Precision Format	Double-Precision Format
Exponent Bias	+127	+1023
Maximum Exponent (Emax)	+127	+1023
Minimum Exponent (Emin)	-126	-1022
Widths (bits):		
Format	32	64
Sign	1	1
Exponent	8	11
Fraction	23	52
Significand	24	53
Nmax	$(1-2^{-24}) \times 2^{128} \approx 3.4 \times 10^{38}$	$(1-2^{-53}) \times 2^{1024} \approx 1.8 \times 10^{308}$
Nmin	$1.0 \times 2^{-126} \approx 1.2 \times 10^{-38}$	$1.0 \times 2^{-1022} \approx 2.2 \times 10^{-308}$
Dmin	$1.0 \times 2^{-149} \approx 1.4 \times 10^{-45}$	$1.0 \times 2^{-1074} \approx 4.9 \times 10^{-324}$

≈ Value is approximate

Dmin Smallest (in magnitude) representable denormalized number.

Nmax Largest (in magnitude) representable number.

Nmin Smallest (in magnitude) representable normalized number.

Table 3. IEEE floating-point fields

7.3.2.2 Value Representation

This architecture defines numeric and nonnumeric values representable within each of the two supported formats. The numeric values are approximations to the real numbers and include the normalized numbers, denormalized numbers, and zero values. The nonnumeric values representable are the infinities and the Not a Numbers (NaNs). The infinities are adjoined to the real numbers, but are not numbers themselves, and the standard rules of arithmetic do not hold when they are used in an operation. They are related to the real numbers by order alone. It is possible however to define restricted operations among numbers and infinities as defined below. The relative location on the real number line for each of the defined entities is shown in Figure 112.

Figure 112. Approximation to real numbers

The NaNs are not related to the numeric values or infinities by order or value but are encodings used to convey diagnostic information such as the representation of uninitialized variables.

The following is a description of the different floating-point values defined in the architecture:

Binary floating-point numbers

Machine representable values used as approximations to real numbers. Three categories of numbers are supported: normalized numbers, denormalized numbers, and zero values.

Normalized numbers (\pm NOR)

These are values that have a biased exponent value in the range:

1 to 254 in single-precision format
1 to 2046 in double-precision format

They are values in which the implied unit bit is 1. Normalized numbers are interpreted as follows:

$$\text{NOR} = (-1)^s \times 2^E \times (1.\text{fraction})$$

where s is the sign, E is the unbiased exponent, and $1.\text{fraction}$ is the significand, which is composed of a leading unit bit (implied bit) and a fraction part.

Zero values (± 0)

These are values that have a biased exponent value of zero and a fraction value of zero. Zeros can have a positive or negative sign. The sign of zero is ignored by comparison operations (that is, comparison regards $+0$ as equal to -0).

Denormalized numbers (\pm DEN)

These are values that have a biased exponent value of zero and a nonzero fraction value. They are nonzero numbers smaller in magnitude than the representable normalized numbers. They are values in which the implied unit bit is 0. Denormalized numbers are interpreted as follows:

$$\text{DEN} = (-1)^s \times 2^{E_{\text{min}}} \times (0.\text{fraction})$$

where E_{min} is the minimum representable exponent value (-126 for single-precision, -1022 for double-precision).

Infinities (\pm INF)

These are values that have the maximum biased exponent value:

255 in single-precision format
2047 in double-precision format

and a zero fraction value. They are used to approximate values greater in magnitude than the maximum normalized value.

Infinity arithmetic is defined as the limiting case of real arithmetic, with restricted operations defined among numbers and infinities. Infinities and the real numbers can be related by ordering in the affine sense:

$$-\text{Infinity} < \text{every finite number} < +\text{Infinity}$$

Arithmetic on infinities is always exact and does not signal any exception, except when an exception occurs due to the invalid operations as described in Section 7.4.1, "Floating-Point Invalid Operation Exception" on page 295.

For comparison operations, $+\text{Infinity}$ compares equal to $+\text{Infinity}$ and $-\text{Infinity}$ compares equal to $-\text{Infinity}$.

Not a Numbers (NaNs)

These are values that have the maximum biased exponent value and a nonzero fraction value. The sign bit is ignored (that is, NaNs are neither positive nor negative). If the high-order bit of the fraction field is 0, the NaN is a *Signaling NaN*; otherwise it is a *Quiet NaN*.

Signaling NaNs are used to signal exceptions when they appear as operands of computational instructions.

Quiet NaNs are used to represent the results of certain invalid operations, such as invalid arithmetic operations on infinities or on NaNs, when Invalid Operation exception is disabled (VE=0). Quiet NaNs propagate through all floating-point operations except ordered comparison and conversion to integer. Quiet NaNs do not signal exceptions, except for ordered comparison and conversion to integer operations. Specific encodings in QNaNs can thus be preserved through a sequence of floating-point operations, and used to convey diagnostic information to help identify results from invalid operations.

Assume the following generic arithmetic templates.

```
f(src1,src3,src2)
  ex: result = (src1 x src3) - src2
f(src1,src2)
  ex: result = src1 x src2
  ex: result = src1 + src2
f(src1)
  ex: result = f(src1)
```

When a QNaN is the result of a floating-point operation because one of the operands is a NaN or because a QNaN was generated due to a trap-disabled Invalid Operation exception, the following rule is applied to determine the NaN with the high-order fraction bit set to 1 that is to be stored as the result.

```
if src1 is a NaN
  then result = Quiet(src1)
  else if src2 is a NaN (if there is a src2)
    then result = Quiet(src2)
    else if src3 is a NaN (if there is a src3)
      then result = Quiet(src3)
      else if disabled invalid operation exception
        then result = generated QNaN
```

where Quiet(x) means x if x is a QNaN and x converted to a QNaN if x is an SNaN. Any instruction that generates a QNaN as the result of a disabled Invalid Operation exception generates the value 0x7FF8_0000_0000_0000 for double-precision and 0x7FC0_0000 for single-precision.

Note that the M-form multiply-add-type instructions use the B source operand to specify src3 and the T target operand to specify src2, whereas A-form multiply-add-type instructions use the B source operand to specify src2 and the T target operand to specify src3.

A double-precision NaN is considered to be representable in single-precision format if and only

if the low-order 29 bits of the double-precision NaN's fraction are zero.

7.3.2.3 Sign of Result

The following rules govern the sign of the result of an arithmetic, rounding, or conversion operation, when the operation does not yield an exception. They apply even when the operands or results are zeros or infinities.

- The sign of the result of an add operation is the sign of the operand having the larger absolute value. If both operands have the same signs, the sign of the result of an add operation is the same as the sign of the operands. The sign of the result of the subtract operation $x-y$ is the same as the sign of the result of the add operation $x+(-y)$.

When the sum of two operands with opposite sign, or the difference of two operands with the same signs, is exactly zero, the sign of the result is positive in all rounding modes except Round toward $-\infty$, in which mode the sign is negative.

- The sign of the result of a multiply or divide operation is the Exclusive OR of the signs of the operands.
- The sign of the result of a *Square Root* or *Reciprocal Square Root Estimate* operation is always positive, except that the square root of -0 is -0 and the reciprocal square root of -0 is $-\infty$.
- The sign of the result of a *Convert From Integer* or *Round to Floating-Point Integer* operation is the sign of the operand being converted.

For the *Multiply-Add* instructions, the rules given above are applied first to the multiply operation and then to the add or subtract operation (one of the inputs to the add or subtract operation is the result of the multiply operation).

7.3.2.4 Normalization and Denormalization

The intermediate result of an arithmetic instruction can require normalization and/or denormalization as described below. Normalization and denormalization do not affect the sign of the result.

When an arithmetic or rounding instruction produces an intermediate result which carries out of the significand, or in which the significand is nonzero but has a leading zero bit, it is not a normalized number and must be normalized before it is stored. For the

carry-out case, the significand is shifted right one bit, with a one shifted into the leading significand bit, and the exponent is incremented by one. For the leading-zero case, the significand is shifted left while decrementing its exponent by one for each bit shifted, until the leading significand bit becomes one. The Guard bit and the Round bit (see Section 7.3.3.1, “VSX Execution Model for IEEE Operations” on page 289) participate in the shift with zeros shifted into the Round bit. The exponent is regarded as if its range were unlimited.

After normalization, or if normalization was not required, the intermediate result can have a nonzero significand and an exponent value that is less than the minimum value that can be represented in the format specified for the result. In this case, the intermediate result is said to be “Tiny” and the stored result is determined by the rules described in Section 7.4.4, “Floating-Point Underflow Exception” on page 306. These rules can require denormalization.

A number is denormalized by shifting its significand right while incrementing its exponent by 1 for each bit shifted, until the exponent is equal to the format’s minimum value. If any significant bits are lost in this shifting process, “Loss of Accuracy” has occurred (See Section 7.4.4, “Floating-Point Underflow Exception” on page 306) and Underflow exception is signaled.

Engineering Note

When denormalized numbers are operands of multiply, divide, and square root operations, some implementations might prenormalize the operands internally before performing the operations.

7.3.2.5 Data Handling and Precision

Instructions are also provided for manipulations which do not require double-precision or single-precision. In addition, instructions are provided to access an integer representation in GPRs.

Integer-Valued Operands

Instructions are provided to round floating-point operands to integer values in floating-point format. To facilitate exchange of data between the floating-point and integer processing, instructions are provided to convert between floating-point double and single-precision format and integer word and doubleword format in a VSR. Computation on integer-valued operands can be performed using arithmetic instructions of the required precision. (The results might not be integer values.) The three groups of instructions provided specifically to support integer-valued operands are described below.

1. Rounding to a floating-point integer

The *VSX Scalar Round to Floating-Point Integer* instructions round a double-precision operand to an integer value in double-precision format.

The *VSX Vector Round to Double-Precision Integer* instructions round each double-precision vector operand element to an integer value in double-precision format.

The *VSX Vector Round to Single-Precision Integer* instructions round each single-precision vector operand element to an integer value in single-precision format.

Except for *xsrpic*, *xvrpic*, and *xvrspic*, rounding is performed using the rounding mode specified by the opcode. For *xsrpic*, *xvrpic*, and *xvrspic*, rounding is performed using the rounding mode specified by RN. These instructions can cause Invalid Operation (VXSNaN) exceptions. *xsrpic*, *xvrpic*, and *xvrspic* can also cause Inexact exception. See Sections 7.3.2.6 and 7.3.3.1 for more information about rounding.

2. Converting floating-point format to integer format

The *VSX Scalar Convert Double-Precision to Integer* instructions convert a double-precision operand to 32-bit or 64-bit signed or unsigned integer format.

The *VSX Vector Convert Double-Precision to Integer* and *VSX Vector Convert Single-Precision to Integer* instructions convert either double-precision or single-precision vector operand elements to 32-bit or 64-bit signed or unsigned integer format.

Rounding is performed based on the value of RN. These instructions can cause Invalid Operation (VXSNaN, VXCVI) and Inexact exceptions.

3. Converting integer format to floating-point format

The *VSX Scalar Convert Integer to Double-Precision* instructions convert a 32-bit or 64-bit signed or unsigned integer to double-precision floating-point format.

The *VSX Vector Convert Integer to Double-Precision* instructions convert each 32-bit or 64-bit signed or unsigned integer vector operand element to double-precision floating-point format.

The *VSX Vector Convert Integer to Single-Precision* instructions convert each 32-bit

or 64-bit signed or unsigned integer vector operand element to single-precision floating-point format.

Rounding is performed using Round towards Zero rounding mode. Because of the limitations of the source format, only an Inexact exception can be generated.

7.3.2.6 Rounding

The material in this section applies to operations that have numeric operands (that is, operands that are not infinities or NaNs). Rounding the intermediate result of such an operation can cause an Overflow exception, an Underflow exception, or an Inexact exception. The remainder of this section assumes that the operation causes no exceptions and that the result is numeric. See Section 7.3.2.2, “Value Representation” and Section 7.4, “VSX Floating-Point Exceptions” for the cases not covered here.

The floating-point arithmetic, and rounding and conversion instructions round their intermediate results. With the exception of the estimate instructions, these instructions produce an intermediate result that can be regarded as having unbounded precision and exponent range. All but two groups of these instructions normalize or denormalize the intermediate result prior to rounding and then place the final result into the target element of the target VSR in either double or single-precision format.

The scalar round to double-precision integer, vector round to double-precision integer, and convert double-precision to integer instructions with biased exponents ranging from 1022 through 1074 are prepared for rounding by repetitively shifting the significand right one position and incrementing the biased exponent until it reaches a value of 1075. (Intermediate results with biased exponents 1075 or larger are already integers, and with biased exponents 1021 or less round to zero.) After rounding, the final result for round to double-precision integer instructions is normalized and put in double-precision format, and, for the convert double-precision to integer instructions, is converted to a signed or unsigned integer.

The vector round to single-precision integer and vector convert single-precision to integer instructions with biased exponents ranging from 126 through 178 are prepared for rounding by repetitively shifting the significand right one position and incrementing the biased exponent until it reaches a value of 179. (Intermediate results with biased exponents 179 or larger are already integers, and with biased exponents 125 or less round to zero.) After rounding, the final result for vector round to single-precision integer is normalized and put in double-precision format, and for

vector convert single-precision to integer is converted to a signed or unsigned integer.

FR and FI generally indicate the results of rounding. Each of the scalar instructions which rounds its intermediate result sets these bits. There are no vector instructions that modify FR and FI. If the fraction is incremented during rounding, FR is set to 1, otherwise FR is set to 0. If the result is inexact, FI is set to 1, otherwise FI is set to zero. The scalar round to double-precision integer instructions are exceptions to this rule, setting FR and FI to 0. The scalar double-precision estimate instructions set FR and FI to undefined values. The remaining scalar floating-point instructions do not alter FR and FI.

Four user-selectable rounding modes are provided through the Floating-Point Rounding Control field in the FPSCR. See Section 7.2.2, “Floating-Point Status and Control Register” on page 276. These are encoded as follows.

RN	Rounding Mode
00	Round to Nearest Even
01	Round towards Zero
10	Round towards +Infinity
11	Round towards -Infinity

A fifth rounding mode is provided in the round to floating-point integer instructions (Section 7.6.7.2 on page 320), Round to Nearest Away.

Let Z be the intermediate arithmetic result or the operand of a convert operation. If Z can be represented exactly in the target format, the result in all rounding modes is Z as represented in the target format. If Z cannot be represented exactly in the target format, let $Z1$ and $Z2$ bound Z as the next larger and next smaller numbers representable in the target format. Then $Z1$ or $Z2$ can be used to approximate the result in the target format.

Figure 113 shows the relation of Z , $Z1$, and $Z2$ in this case. The following rules specify the rounding in the four modes.

See Section 7.3.3.1, “VSX Execution Model for IEEE Operations” on page 289 for a detailed explanation of rounding.

Figure 113 also summarizes the rounding actions for floating-point intermediate result for all supported rounding modes.

**Round to Nearest Away**

Choose the value that is closer to Z (Z1 or Z2). In case of a tie, choose the one that is furthest away from 0.

Round to Nearest Even

Choose the value that is closer to Z (Z1 or Z2). In case of a tie, choose the one that is even (least significant bit is 0).

Round toward Zero

Choose the smaller in magnitude (Z1 or Z2).

Round toward +Infinity

Choose Z1.

Round toward -Infinity

Choose Z2.

Figure 113. Selection of Z1 and Z2

7.3.3 VSX Floating-Point Execution Models

All implementations of this architecture must provide the equivalent of the following execution models to ensure that identical results are obtained.

Special rules are provided in the definition of the computational instructions for the infinities, denormalized numbers and NaNs. The material in the remainder of this section applies to instructions that have numeric operands and a numeric result (that is, operands and result that are not infinities or NaNs), and that cause no exceptions. See Section 7.3.2.2 and Section 7.3.3 for the cases not covered here.

Although the double-precision format specifies an 11-bit exponent, exponent arithmetic makes use of two additional bits to avoid potential transient overflow and underflow conditions. One extra bit is required when denormalized double-precision numbers are prenormalized. The second bit is required to permit the computation of the adjusted exponent value in the following cases when the corresponding exception enable bit is 1:

- Underflow during multiplication using a denormalized operand.
- Overflow during division using a denormalized divisor.
- Underflow during division using denormalized dividend and a large divisor.

The IEEE standard includes 32-bit and 64-bit arithmetic. The standard requires that single-precision arithmetic be provided for single-precision operands.

VSX defines both scalar and vector double-precision floating-point operations to operate only on double-precision operands. VSX also defines vector single-precision floating-point operations to operate only on single-precision operands.

7.3.3.1 VSX Execution Model for IEEE Operations

The following description uses 64-bit arithmetic as an example. 32-bit arithmetic is similar except that the FRACTION is a 23-bit field, and the single-precision Guard, Round, and Sticky bits (described in this section) are logically adjacent to the 23-bit FRACTION field.

IEEE-conforming significand arithmetic is considered to be performed with a floating-point accumulator

having the following format, where bits 0:55 comprise the significand of the intermediate result.

Figure 114. IEEE floating-point execution model

The S bit is the sign bit.

The C bit is the carry bit, which captures the carry out of the significand.

The L bit is the leading unit bit of the significand, which receives the implicit bit from the operand.

The FRACTION is a 52-bit field that accepts the fraction of the operand.

The Guard (G), Round (R), and Sticky (X) bits are extensions to the low-order bits of the accumulator. The G and R bits are required for postnormalization of the result. The G, R, and X bits are required during rounding to determine if the intermediate result is equally near the two nearest representable values. The X bit serves as an extension to the G and R bits by representing the logical OR of all bits that appear to the low-order side of the R bit, resulting from either shifting the accumulator right or to other generation of low-order result bits. The G and R bits participate in the left shifts with zeros being shifted into the R bit. Table 4 shows the significance of the G, R, and X bits with respect to the intermediate result (IR), the representable number next lower in magnitude (NL), and the representable number next higher in magnitude (NH).

G	R	X	Interpretation
0	0	0	IR is exact
0	0	1	IR closer to NL
0	1	0	
0	1	1	IR closer to NH
1	0	0	
1	0	1	IR closer to NH
1	1	0	
1	1	1	

Table 4. Interpretation of G, R, and X bits

Table 5 shows the positions of the Guard, Round, and Sticky bits for double-precision and single-precision floating-point numbers relative to the accumulator illustrated in Figure 114.

Format	Guard	Round	Sticky
Double	G bit	R bit	X bit
Single	24	25	OR of bits 26:52, G, R, X

Table 5. Location of the Guard, Round, and Sticky bits in the IEEE execution model

The significand of the intermediate result is prepared for rounding by shifting its contents right, if required, until the least significant bit to be retained is in the low-order bit position of the fraction.

Four user-selectable rounding modes are provided through RN as described in Section 7.3.2.6, “Rounding” on page 287. The rules for rounding in each mode are as follows.

– **Round to Nearest Even**

Guard bit = 0

The result is truncated.

Guard bit = 1

Depends on Round and Sticky bits:

Case a

If the Round or Sticky bit is 1 (inclusive), the result is incremented.

Case b

If the Round and Sticky bits are 0 (result midway between closest representable values), if the low-order bit of the result is 1, the result is incremented. Otherwise (the low-order bit of the result is 0), the result is truncated. This is the case of a tie rounded to even.

– **Round toward Zero**

Choose the smaller in magnitude of Z1 or Z2. If the Guard, Round, or Sticky bit is nonzero, the result is inexact.

The result is truncated.

– **Round toward +Infinity**

If positive, the result is incremented.

If negative, the result is truncated.

– **Round toward -Infinity**

If positive, the result is truncated.

If negative, the result is incremented.

A fifth rounding mode is provided in the *VSX Round to Floating-Point Integer* instructions (Section 7.6.7.2 on page 320) with the rules for rounding as follows.

– **Round to Nearest Away**

Guard bit = 0

The result is truncated.

Guard bit = 1

The result is incremented.

If any of the Guard, Round, or Sticky bits is nonzero, the result is also inexact.

If rounding results in a carry into C, the significand is shifted right one position and the exponent is incremented by one. This yields an inexact result, and possibly also exponent overflow. Fraction bits are stored to the target VSR.

7.3.3.2 VSX Execution Model for Multiply-Add Type Instructions

This architecture provides a special form of instruction that performs up to three operations in one instruction (a multiplication, an addition, and a negation). With this added capability comes the special ability to produce a more exact intermediate result as input to the rounder. 32-bit arithmetic is similar, except that the FRACTION field is smaller.

Multiply-add significand arithmetic is considered to be performed with a floating-point accumulator having the following format, where bits 0:106 comprise the significand of the intermediate result.

Figure 115. Multiply-add 64-bit execution model

The first part of the operation is a multiplication. The multiplication has two 53-bit significands as inputs, which are assumed to be prenormalized, and produces a result conforming to the above model. If there is a carry out of the significand (into the C bit), the significand is shifted right one position, shifting the L bit (leading unit bit) into the most significant bit of the FRACTION and shifting the C bit (carry out) into the L bit. All 106 bits (L bit, the FRACTION) of the product take part in the add operation. If the exponents of the two inputs to the adder are not equal, the significand of the operand with the smaller exponent is aligned (shifted) to the right by an amount that is added to that exponent to make it equal to the other input's exponent. Zeros are shifted into the left of the significand as it is aligned and bits shifted out of bit 105 of the significand are ORed into the X' bit. The add operation also produces a result conforming to the above model with the X' bit taking part in the add operation.

The result of the addition is then normalized, with all bits of the addition result, except the X' bit, participating in the shift. The normalized result serves as the intermediate result that is input to the rounder.

For rounding, the conceptual Guard, Round, and Sticky bits are defined in terms of accumulator bits. Figure 6 shows the positions of the Guard, Round, and Sticky bits for double-precision and single-precision floating-point numbers in the multiply-add execution model.

Format	Guard	Round	Sticky
Double	53	54	OR of 55:105, X'
Single	24	25	OR of 26:105, X'

Table 6. Location of the Guard, Round, and Sticky bits in the multiply-add execution model

The rules for rounding the intermediate result are the same as those given in Section 7.3.3.1.

If the instruction is a negative multiply-add or negative multiply-subtract type instruction, the final result is negated.

7.4 VSX Floating-Point Exceptions

This architecture defines the following floating-point exceptions under the IEEE-754 exception model:

- Invalid Operation exception
 - SNaN
 - Infinity–Infinity
 - Infinity÷Infinity
 - Zero÷Zero
 - Infinity×Zero
 - Invalid Compare
 - Software-Defined Condition
 - Invalid Square Root
 - Invalid Integer Convert
- Zero Divide exception
- Overflow exception
- Underflow exception
- Inexact exception

These exceptions, other than Invalid Operation exception resulting from a Software-Defined Condition, can occur during execution of computational instructions. An Invalid Operation exception resulting from a Software-Defined Condition occurs when a *Move To FPSCR* instruction sets VXSOFT to 1.

Each floating-point exception, and each category of Invalid Operation exception, has an exception bit in the FPSCR. In addition, each floating-point exception has a corresponding enable bit in the FPSCR. The exception bit indicates the occurrence of the corresponding exception. If an exception occurs, the corresponding enable bit governs the result produced by the instruction and, in conjunction with the FE0 and FE1 bits (see page 293), whether and how the system floating-point enabled exception error handler is invoked. In general, the enabling specified by the enable bit is of invoking the system error handler, not of permitting the exception to occur. The occurrence of an exception depends only on the instruction and its inputs, not on the setting of any control bits. The only deviation from this general rule is that the occurrence of an Underflow exception depends on the setting of the enable bit.

A single instruction, other than *mtfsfi* or *mtfsf*, can set more than one exception bit only in the following cases:

- An Inexact exception can be set with an Overflow exception.
- An Inexact exception can be set with an Underflow exception.

- An Invalid Operation exception (SNaN) is set with an Invalid Operation exception (Infinity×0) for multiply-add class instructions for which the values being multiplied are infinity and zero and the value being added is an SNaN.
- An Invalid Operation exception (SNaN) can be set with an Invalid Operation exception (Invalid Compare) for ordered comparison instructions.
- An Invalid Operation exception (SNaN) can be set with an Invalid Operation exception (Invalid Integer Convert) for convert to integer instructions.

When an exception occurs, the writing of a result to the target register can be suppressed, or a result can be delivered, depending on the exception.

The writing of a result to the target register is suppressed for the certain kinds of exceptions, based on whether the instruction is a vector or a scalar instruction, so that there is no possibility that one of the operands is lost. For other kinds of exceptions and also depending on whether the instruction is a vector or a scalar instruction, a result is generated and written to the destination specified by the instruction causing the exception. The result can be a different value for the enabled and disabled conditions for some of these exceptions. Table 7 lists the types of exceptions and indicates whether a result is written to the target VSR or suppressed.

On exception type...	Scalar Instruction Results	Vector Instruction Results
Enabled Invalid Operation	suppressed	suppressed
Enabled Zero Divide	suppressed	suppressed
Enabled Overflow	written	suppressed
Enabled Underflow	written	suppressed
Enabled Inexact	written	suppressed
Disabled Invalid Operation	written	written
Disabled Zero Divide	written	written
Disabled Overflow	written	written
Disabled Underflow	written	written
Disabled Inexact	written	written

Table 7. Exception Types Result Suppression

The subsequent sections define each of the floating-point exceptions and specify the action that is taken when they are detected.

The IEEE standard specifies the handling of exceptional conditions in terms of *traps* and *trap handlers*. In this architecture, an FPSCR exception enable bit of 1 causes generation of the result value specified in the IEEE standard for the trap enabled case; the expectation is that the exception is detected by software, which revises the result. An FPSCR exception enable bit of 0 causes generation of the default result value specified for the trap disabled (or no trap occurs or trap is not implemented) case. The expectation is that the exception is not detected by software, which uses the default result. The result to be delivered in each case for each exception is described in the following sections.

The IEEE default behavior when an exception occurs is to generate a default value and not to notify software. In this architecture, if the IEEE default behavior when an exception occurs is required for all exceptions, all FPSCR exception enable bits must be set to 0, and Ignore Exceptions Mode (see below) should be used. In this case, the system floating-point enabled exception error handler is not invoked, even if floating-point exceptions occur: software can inspect the FPSCR exception bits, if necessary, to determine whether exceptions have occurred.

In this architecture, if software is to be notified that a given kind of exception has occurred, the corresponding FPSCR exception enable bit must be set to 1, and a mode other than Ignore Exceptions Mode must be used. In this case, the system floating-point enabled exception error handler is invoked if an enabled floating-point exception occurs. The system floating-point enabled exception error handler is also invoked if a *Move To FPSCR* instruction causes an exception bit and the corresponding enable bit both to be 1. The *Move To FPSCR* instruction is considered to cause the enabled exception.

The FE0 and FE1 bits control whether and how the system floating-point enabled exception error handler is invoked if an enabled floating-point exception occurs. The location of these bits and the requirements for altering them are described in Book III. The system floating-point enabled exception error handler is never invoked because of a disabled floating-point exception. The effects of the four possible settings of these bits are as follows.

FE0	FE1	Description
0	0	Ignore Exceptions Mode
0	1	Imprecise Nonrecoverable Mode
1	0	Imprecise Recoverable Mode
1	1	Precise Mode

Architecture Note

The FE0 and FE1 bits must be defined in Book III in a manner such that they can be changed dynamically and can easily be treated as part of a process' state.

In all cases, the question of whether a floating-point result is stored, and what value is stored, is governed by the FPSCR exception enable bits, as described in subsequent sections, and is not affected by the value of the FE0 and FE1 bits.

In all cases in which the system floating-point enabled exception error handler is invoked, all instructions before the instruction at which the system floating-point enabled exception error handler is invoked have been completed, and no instruction after the instruction at which the system floating-point enabled exception error handler is invoked has begun

execution. The instruction at which the system floating-point enabled exception error handler is invoked has completed if it is the excepting instruction, and there is only one such instruction. Otherwise, it has not begun execution, or has been partially executed in some cases, as described in Book III.

Engineering Note

It is permissible for the implementation to be precise in any of the three modes that permit interrupts, or to be recoverable in Nonrecoverable Mode.

Programming Note

In any of the three non-Precise modes, a *Floating-Point Status and Control Register* instruction can be used to force any exceptions, because of instructions initiated before the *Floating-Point Status and Control Register* instruction, to be recorded in the FPSCR. (This forcing is superfluous for Precise Mode.)

In both Imprecise modes, a *Floating-Point Status and Control Register* instruction can be used to force any invocations of the system floating-point enabled exception error handler that result from instructions initiated before the *Floating-Point Status and Control Register* instruction to occur. This forcing has no effect in Ignore Exceptions Mode, and is superfluous for Precise Mode.

The last sentence of the paragraph preceding this Programming Note can apply only in the Imprecise modes, or if the mode has just been changed from Ignore Exceptions Mode to some other mode. It always applies in the latter case.

To obtain the best performance across the widest range of implementations, the programmer should obey the following guidelines.

- If the IEEE default results are acceptable to the application, Ignore Exceptions Mode should be used with all FPSCR exception enable bits set to 0.
- If the IEEE default results are not acceptable to the application, Imprecise Nonrecoverable Mode should be used, or Imprecise Recoverable Mode if recoverability is needed, with FPSCR exception enable bits set to 1 for those exceptions for which the system floating-point enabled exception error handler is to be invoked.
- Ignore Exceptions Mode should not, in general, be used when any FPSCR exception enable bits are set to 1.
- Precise Mode can degrade performance in some implementations, perhaps substantially, and therefore should be used only for debugging and other specialized applications.

7.4.1 Floating-Point Invalid Operation Exception

7.4.1.1 Definition

An Invalid Operation exception occurs when an operand is invalid for the specified operation. The invalid operations are:

SNaN

Any floating-point operation on a Signaling NaN.

Infinity–Infinity

Magnitude subtraction of infinities.

Infinity÷Infinity

Floating-point division of infinity by infinity.

Zero÷Zero

Floating-point division of zero by zero.

Infinity × Zero

Floating-point multiplication of infinity by zero.

Invalid Compare

Floating-point ordered comparison involving a NaN.

Invalid Square Root

Floating-point square root or reciprocal square root of a nonzero negative number.

Invalid Integer Convert

Floating-point-to-integer convert involving a number too large in magnitude to be represented in the target format, or involving an infinity or a NaN.

An Invalid Operation exception also occurs when an *mtfsfi*, *mtfsf*, or *mtfsb1* instruction is executed that sets VXSOFT to 1 (Software-Defined Condition).

The action to be taken depends on the setting of the Invalid Operation Exception Enable bit of the FPSCR.

7.4.1.2 Action for VE=1

When Invalid Operation exception is enabled (VE=1) and an Invalid Operation exception occurs, the following actions are taken:

For *VSX Scalar Floating-Point Arithmetic*, *VSX Scalar DP-SP Conversion*, *VSX Scalar Convert Floating-Point to Integer*, and *VSX Scalar Round to Floating-Point Integer* instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXISI	(if Infinity–Infinity)
VXIDI	(if Infinity÷Infinity)
VXZDZ	(if Zero÷Zero)
VXIMZ	(if Infinity×Zero)
VXSQRT	(if Invalid Square Root)
VXCVI	(if Invalid Integer Convert)

2. Update of VSR[XT] is suppressed.
3. FR and FI are set to zero.
4. FPRF is unchanged.

For *VSX Scalar Floating-Point Compare* instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXVC	(if Invalid Compare)

2. FR, FI, and C are unchanged.
3. FPCC is set to reflect unordered.

For *VSX Vector Floating-Point Arithmetic*, *VSX Vector Floating-Point Compare*, *VSX Vector DP-SP Conversion*, *VSX Vector Convert Floating-Point to Integer*, and *VSX Vector Round to Floating-Point Integer* instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXISI	(if Infinity – Infinity)
VXIDI	(if Infinity ÷ Infinity)
VXZDZ	(if Zero ÷ Zero)
VXIMZ	(if Infinity × Zero)
VXVC	(if Invalid Compare)
VXSQRT	(if Invalid Square Root)
VXCVI	(if Invalid Integer Convert)

2. Update of VSR[XT] is suppressed for all

- vector elements.
- 3. FR and FI are unchanged.
- 4. FPRF is unchanged.

7.4.1.3 Action for VE=0

When Invalid Operation exception is disabled (VE=0) and an Invalid Operation exception occurs, the following actions are taken:

For the *VSX Scalar round and Convert Double-Precision to Single-Precision format (xscvdpsp)* instruction:

1. VXSNAN is set to 1.
2. The single-precision representation of a Quiet NaN is placed into word element 0 of VSR[XT]. The contents of word elements 1-3 of VSR[XT] are undefined.
3. FR and FI are set to 0.
4. FPRF is set to indicate the class of the result (Quiet NaN).

For the *VSX Vector Single-Precision Arithmetic instructions, VSX Vector Single-Precision Maximum/Minimum instructions, the VSX Vector round and Convert Double-Precision to Single-Precision format (xvcvdpsp)* instruction, and the *VSX Vector Round to Single-Precision Integer instructions*:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXISI	(if Infinity – Infinity)
VXIDI	(if Infinity ÷ Infinity)
VXZDZ	(if Zero ÷ Zero)
VXIMZ	(if Infinity × Zero)
VXSQRT	(if Invalid Square Root)

2. The single-precision representation of a Quiet NaN is placed into its respective word element of VSR[XT].
3. FR, FI, and FPRF are not modified.

For the *VSX Scalar Double-Precision Arithmetic instructions, VSX Scalar Double-Precision Maximum/Minimum instructions, the VSX Scalar Convert Single-Precision to Double-Precision format (xscvspdp)* instruction, and the *VSX Scalar Round to Double-Precision Integer instructions*:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXISI	(if Infinity – Infinity)
VXIDI	(if Infinity ÷ Infinity)
VXZDZ	(if Zero ÷ Zero)
VXIMZ	(if Infinity × Zero)
VXSQRT	(if Invalid Square Root)

2. The double-precision representation of a Quiet NaN is placed into doubleword element 0 of VSR[XT]. The contents of doubleword element 1 of VSR[XT] are undefined.

3. FR and FI are set to 0.

4. FPRF is set to indicate the class of the result (Quiet NaN).

For the *VSX Vector Double-Precision Arithmetic instructions, VSX Vector Double-Precision Maximum/Minimum instructions, the VSX Vector Convert Single-Precision to Double-Precision format (xvcvspdp)* instruction, and the *VSX Vector Round to Double-Precision Integer instructions*:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXISI	(if Infinity – Infinity)
VXIDI	(if Infinity ÷ Infinity)
VXZDZ	(if Zero ÷ Zero)
VXIMZ	(if Infinity × Zero)
VXSQRT	(if Invalid Square Root)

2. The double-precision representation of a Quiet NaN is placed into its respective doubleword element of VSR[XT].

3. FR, FI, and FPRF are not modified.

For the *VSX Scalar Convert Double-Precision to Signed Integer Doubleword (xscvdpsxd)* instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)
VXCVI (if Invalid Integer Convert)

2. `0x7FFF_FFFF_FFFF_FFFF` is placed into doubleword element 0 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a positive number or +Infinity.

`0x8000_0000_0000_0000` is placed into doubleword element 0 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a negative number, -Infinity, or NaN.

The contents of doubleword element 1 of VSR[XT] are undefined.

3. FR and FI are set to 0.
4. FPRF is undefined.

For the *VSX Scalar Convert Double-Precision to Signed Integer Word (xscvdpsxw)* instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)
VXCVI (if Invalid Integer Convert)

2. `0x7FFF_FFFF` is placed into word element 1 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a positive number or +Infinity.

`0x8000_0000` is placed into word element 1 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a negative number, -Infinity, or NaN.

The contents of word elements 0, 2, and 3 of VSR[XT] are undefined.

3. FR and FI are set to 0.
4. FPRF is undefined.

For the *VSX Scalar Convert Double-Precision to Unsigned Integer Doubleword (xscvdpuxd)* instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)
VXCVI (if Invalid Integer Convert)

2. `0xFFFF_FFFF_FFFF_FFFF` is placed into doubleword element 0 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a positive number or +Infinity.

`0x0000_0000_0000_0000` is placed into doubleword element 0 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a negative number, -Infinity, or NaN.

The contents of doubleword element 1 of VSR[XT] are undefined.

3. FR and FI are set to 0.
4. FPRF is undefined.

For the *VSX Scalar Convert Double-Precision to Unsigned Integer Word (xscvdpuxw)* instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)
VXCVI (if Invalid Integer Convert)

2. `0xFFFF_FFFF` is placed into word element 1 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a positive number or +Infinity.

`0x0000_0000` is placed into word element 1 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a negative number, -Infinity, or NaN.

The contents of word elements 0, 2, and 3 of VSR[XT] are undefined.

3. FR and FI are set to 0.
4. FPRF is undefined.

For the *VSX Vector Convert Double-Precision to Signed Integer Doubleword* (***xvcvdpsxd***) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)
VXCVI (if Invalid Integer Convert)

2. `0x7FFF_FFFF_FFFF_FFFF` is placed into doubleword element *i* of VSR[XT] if the double-precision operand in the corresponding doubleword element of VSR[XB] is a positive number or +Infinity.

`0x8000_0000_0000_0000` is placed into its respective doubleword element *i* of VSR[XT] if the double-precision operand in the corresponding doubleword element of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.

For the *VSX Vector Convert Double-Precision to Signed Integer Word* (***xvcvdpsxw***) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)
VXCVI (if Invalid Integer Convert)

2. `0x7FFF_FFFF` is placed into word element *ix2* of VSR[XT] if the double-precision operand in doubleword element *i* of VSR[XB] is a positive number or +Infinity.

`0x8000_0000` is placed into word element *ix2* of VSR[XT] if the double-precision operand in doubleword element *i* of VSR[XB] is a negative number, -Infinity, or NaN.

The contents of word element *ix2+1* of VSR[XT] are undefined.

3. FR, FI, and FPRF are not modified.

For the *VSX Vector Convert Double-Precision to Unsigned Integer Doubleword* (***xvcvdpuxd***) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)
VXCVI (if Invalid Integer Convert)

2. `0xFFFF_FFFF_FFFF_FFFF` is placed into doubleword element *i* of VSR[XT] if the double-precision operand in doubleword element *i* of VSR[XB] is a positive number or +Infinity.

`0x0000_0000_0000_0000` is placed into doubleword element *i* of VSR[XT] if the double-precision operand in doubleword element *i* of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.

For the *VSX Vector Convert Double-Precision to Unsigned Integer Word* (***xvcvdpuxw***) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)
VXCVI (if Invalid Integer Convert)

2. `0xFFFF_FFFF` is placed into word element *ix2* of VSR[XT] if the double-precision operand in doubleword element *i* of VSR[XB] is a positive number or +Infinity.

`0x0000_0000` is placed into word element *ix2* of VSR[XT] if the double-precision operand in doubleword element *i* of VSR[XB] is a negative number, -Infinity, or NaN.

The contents of word element *ix2+1* of VSR[XT] are undefined.

3. FR, FI, and FPRF are not modified.

For the *VSX Vector Convert Single-Precision to Signed Integer Doubleword* (***xvcvpsxd***) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)
VXCVI (if Invalid Integer Convert)

2. `0x7FFF_FFFF_FFFF_FFFF` is placed into doubleword element *i* of VSR[XT] if the single-precision operand in word element *i*×2 of VSR[XB] is a positive number or +Infinity.

`0x8000_0000_0000_0000` is placed into doubleword element *i* of VSR[XT] if the single-precision operand in word element *i*×2 of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.

For the *VSX Vector Convert Single-Precision to Signed Integer Word* (***xvcvpsxw***) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)
VXCVI (if Invalid Integer Convert)

2. `0x7FFF_FFFF` is placed into word element *i* of VSR[XT] if the single-precision operand in word element *i* of VSR[XB] is a positive number or +Infinity.

`0x8000_0000` is placed into word element *i* of VSR[XT] if the single-precision operand in word element *i* of VSR[XB] is a negative number, -Infinity, or NaN.

The contents of word element *i*×2+1 of VSR[XT] are undefined.

3. FR, FI, and FPRF are not modified.

For the *VSX Vector Convert Single-Precision to Unsigned Integer Doubleword* (***xvcvspuxd***) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)
VXCVI (if Invalid Integer Convert)

2. `0xFFFF_FFFF_FFFF_FFFF` is placed into doubleword element *i* of VSR[XT] if the single-precision operand in word element *i*×2 of VSR[XB] is a positive number or +Infinity.

`0x0000_0000_0000_0000` is placed into doubleword element *i* of VSR[XT] if the single-precision operand in word element *i*×2 of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.

For the *VSX Vector Convert Single-Precision to Unsigned Integer Word* (***xvcvspuxw***) instruction:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)
VXCVI (if Invalid Integer Convert)

2. `0xFFFF_FFFF` is placed into word element *i* of VSR[XT] if the single-precision operand in the corresponding word element *i*×2 of VSR[XB] is a positive number or +Infinity.

`0x0000_0000` is placed into word element *i* of VSR[XT] if the single-precision operand in word element *i*×2 of VSR[XB] is a negative number, -Infinity, or NaN.

The contents of word element *i*×2+1 of VSR[XT] are undefined.

3. FR, FI, and FPRF are not modified.

For the *VSX Scalar Floating-Point Compare* instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXVC	(if invalid compare)

2. FR, FI and C are unchanged.
3. FPCC is set to reflect unordered.

For the *VSX Vector Compare Single-Precision* instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXVC	(if invalid compare)

2. 0x0000_0000 is placed into its respective word element of VSR[XT].
3. FR, FI, and FPRF are not modified.

For the vector double-precision compare instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXVC	(if invalid compare)

2. 0x0000_0000_0000_0000 is placed into its respective doubleword element of VSR[XT].
3. FR, FI, and FPRF are not modified.

7.4.2 Floating-Point Zero Divide Exception

7.4.2.1 Definition

A Zero Divide exception occurs when a *VSX Scalar Divide Double-Precision* (***xsdvdp***), *VSX Vector Divide Double-Precision* (***xvdivdp***), or *VSX Vector Divide Single-Precision* (***xvdivsp***) instruction is executed with a zero divisor value and a finite nonzero dividend value.

It also occurs when a *VSX Scalar Reciprocal Estimate Double-Precision* (***xsredp***), *VSX Vector Reciprocal Estimate Double-Precision* (***xvredp***), *VSX Vector Reciprocal Estimate Single-Precision* (***xvresp***), *VSX Scalar Reciprocal Square Root Estimate Double-Precision* (***xrsqrtdp***), *VSX Vector Reciprocal Square Root Estimate Double-Precision* (***xvrsqrtdp***), or *VSX Vector Reciprocal Square Root Estimate Single-Precision* (***xvrsqrtesp***) instruction is executed with an operand value of zero.

The action to be taken depends on the setting of the Zero Divide Exception Enable bit of the FPSCR.

7.4.2.2 Action for ZE=1

When Zero Divide exception is enabled (ZE=1) and a Zero Divide exception occurs, the following actions are taken:

For the *VSX Scalar Divide Double-Precision* (***xsdvdp***), *VSX Scalar Reciprocal Estimate Double-Precision* (***xsredp***), and *VSX Scalar Reciprocal Square Root Estimate Double-Precision* (***xrsqrtdp***) instructions:

1. ZX is set to 1.
2. Update of VSR[XT] is suppressed.
3. FR and FI are set to 0.
4. FPRF is unchanged.

For the *VSX Vector Divide Double-Precision* (***xvdivdp***), *VSX Vector Divide Single-Precision* (***xvdivsp***), *VSX Vector Reciprocal Estimate Double-Precision* (***xvredp***), *VSX Vector Reciprocal Estimate Single-Precision* (***xvresp***), *VSX Vector Reciprocal Square Root Estimate Double-Precision* (***xvrsqrtdp***), or *VSX Vector Reciprocal Square Root Estimate Single-Precision* (***xvrsqrtesp***) instructions:

1. ZX is set to 1.
2. Update of VSR[XT] is suppressed for all vector elements.
3. FR and FI are unchanged.
4. FPRF is unchanged.

7.4.2.3 Action for ZE=0

When Zero Divide exception is disabled (ZE=0) and a Zero Divide exception occurs, the following actions are taken:

For the *VSX Scalar Divide Double-Precision* (***xsdvdp***) instruction:

1. ZX is set to 1.
2. The double-precision representation of Infinity, where the sign is determined by the XOR of the signs of the operands, is placed into doubleword element 0 of VSR[XT]. The contents of doubleword element 1 of VSR[XT] are undefined.
3. FR and FI are set to 0.
4. FPRF is set to indicate the class and sign of the result (\pm Infinity).

For the *VSX Vector Divide Double-Precision* (***xvdivdp***) instructions:

1. ZX is set to 1.
2. The double-precision representation of Infinity, where the sign is determined by the XOR of the signs of the operands, is placed into its respective doubleword element of VSR[XT].
3. FR, FI, and FPRF are not modified.

For the *VSX Vector Divide Single-Precision* (***xvdivsp***) instructions:

1. ZX is set to 1.
2. The single-precision representation of Infinity, where the sign is determined by the XOR of the signs of the operands, is placed into its respective word element of VSR[XT].
2. The result is placed into its respective word element of VSR[XT] as a single-precision value.
3. FR, FI, and FPRF are not modified.

For the *VSX Scalar Reciprocal Estimate Double-Precision* (***xsredp***) and *VSX Scalar Reciprocal Square Root Estimate Double-Precision* (***xrsqrtedp***) instructions:

1. ZX is set to 1.
2. The double-precision representation of Infinity, where the sign is the sign of the operand, is placed into doubleword element 0 of VSR[XT]. The contents of doubleword element 1 of VSR[XT] are undefined.
3. FR and FI are set to 0.
4. FPRF is set to indicate the class and sign of the result (\pm Infinity).

For the *VSX Vector Reciprocal Estimate Double-Precision* (***xvredp***) and *VSX Vector Reciprocal Square Root Estimate Double-Precision* (***xvrsqrtedp***) instructions:

1. ZX is set to 1.
2. The double-precision representation of Infinity, where the sign is the sign of the operand, is placed into its respective doubleword element of VSR[XT].
3. FR, FI, and FPRF are not modified.

For the *VSX Vector Reciprocal Estimate Single-Precision* (***xvresp***) and *VSX Vector Reciprocal Square Root Estimate Single-Precision* (***xvrsqrtesp***) instructions:

1. ZX is set to 1.
2. The single-precision representation of Infinity, where the sign is the sign of the operand, is placed into its respective word element of VSR[XT].
2. The result is placed into its respective word element of VSR[XT] as a single-precision value.
3. FR, FI, and FPRF are not modified.

7.4.3 Floating-Point Overflow Exception

7.4.3.1 Definition

An Overflow exception occurs when the magnitude of what would have been the rounded result if the exponent range were unbounded exceeds that of the largest finite number of the specified result precision.

The action to be taken depends on the setting of the Overflow Exception Enable bit of the FPSCR.

7.4.3.2 Action for OE=1

When Overflow exception is enabled (OE=1) and an Overflow exception occurs, the following actions are taken:

For the *VSX Vector round and Convert Double-Precision to Single-Precision format (xscvdpdp)* instruction:

1. OX is set to 1.
2. The exponent of the normalized intermediate result is adjusted by subtracting 192.
3. The adjusted rounded result is placed into word element 0 of VSR[XT] as a single-precision value. The contents of word elements 1-3 of VSR[XT] are undefined.
4. FPRF is set to indicate the class and sign of the result (\pm Normal Number).

For *VSX Scalar Add Double-Precision (xsadddp)*, *VSX Scalar Divide Double-Precision (xsdivdp)*, *VSX Scalar Multiply Double-Precision (xsmuldp)*, *VSX Scalar Reciprocal Estimate Double-Precision (xsredp)*, *VSX Scalar Subtract Double-Precision (xssubdp)*, and *VSX Scalar Double-Precision Multiply-Add Arithmetic* instructions:

1. OX is set to 1.
2. The exponent of the normalized intermediate result is adjusted by subtracting 1536.
3. The adjusted rounded result is placed into doubleword element 0 of VSR[XT] as a double-precision value. The contents of doubleword element 1 of VSR[XT] are undefined.
4. FPRF is set to indicate the class and sign of the result (\pm Normal Number).

For *VSX Vector Add Double-Precision (xvadddp)*, *VSX Vector Add Single-Precision (xvaddsp)*, *VSX Vector Divide Double-Precision (xvdivdp)*, *VSX Vector Divide Single-Precision (xvdivsp)*, *VSX Vector Multiply Double-Precision (xvmuldp)*, *VSX Vector Multiply Single-Precision (xvmulsp)*, *VSX Vector Reciprocal Estimate Double-Precision (xvredp)*, *VSX Vector Reciprocal Estimate Single-Precision (xvresp)*, *VSX Vector round and Convert Double-Precision to Single-Precision format (xvcvdpdp)*, *VSX Vector Subtract Double-Precision (xvsubdp)*, *VSX Vector Subtract Single-Precision (xvsubsp)*, *VSX Vector Double-Precision Multiply-Add Arithmetic*, and *VSX Vector Single-Precision Multiply-Add Arithmetic* instructions:

1. OX is set to 1.
2. Update of VSR[XT] is suppressed for all vector elements.
3. FR, FI, and FPRF are not modified.

7.4.3.3 Action for OE=0

When Overflow exception is disabled (OE=0) and an Overflow exception occurs, the following actions are taken:

1. OX and XX are set to 1.
2. The result is determined by the rounding mode (RN) and the sign of the intermediate result as follows:

Round to Nearest Even

For negative overflow, the result is -Infinity.

For positive overflow, the result is +Infinity.

Round toward Zero

For negative overflow, the result is the format's most negative finite number.

For positive overflow, the result is the format's most positive finite number.

Round toward +Infinity

For negative overflow, the result is the format's most negative finite number.

For positive overflow, the result is +Infinity.

Round toward $-\infty$

For negative overflow, the result is $-\infty$.

For positive overflow, the result is the format's most positive finite number.

For the *VSX Vector round and Convert Double-Precision to Single-Precision format* (***xscvdp***) instruction:

3. The result is placed into word element 0 of VSR[XT] as a single-precision value. The contents of word elements 1-3 of VSR[XT] are undefined.
4. FR is undefined.
5. FI is set to 1.
6. FPRF is set to indicate the class and sign of the result ($\pm\infty$ or \pm Normal Number).

For *VSX Scalar Add Double-Precision* (***xsaddp***), *VSX Scalar Divide Double-Precision* (***xsdivp***), *VSX Scalar Multiply Double-Precision* (***xsmulp***), *VSX Scalar Reciprocal Estimate Double-Precision* (***xsredp***), *VSX Scalar Subtract Double-Precision* (***xssubp***), and *VSX Scalar Double-Precision Multiply-Add Arithmetic* instructions:

3. The result is placed into doubleword element 0 of VSR[XT] as a double-precision value. The contents of doubleword element 1 of VSR[XT] are undefined.
4. FR is undefined.
5. FI is set to 1.
6. FPRF is set to indicate the class and sign of the result ($\pm\infty$ or \pm Normal Number).

For *VSX Vector Add Single-Precision* (***xvaddsp***), *VSX Vector Divide Single-Precision* (***xvdivsp***), *VSX Vector Multiply Single-Precision* (***xvmulsp***), *VSX Vector Reciprocal Estimate Single-Precision* (***xvresp***), *VSX Vector round and Convert Double-Precision to Single-Precision format* (***xvcvdp***), *VSX Vector Subtract Single-Precision* (***xvsubsp***), and *VSX Vector Single-Precision Multiply-Add Arithmetic* instructions:

3. The result is placed into its respective word element of VSR[XT] as a single-precision value.
4. FR, FI, and FPRF are not modified.

For *VSX Vector Add Double-Precision* (***xvaddp***), *VSX Vector Divide Double-Precision* (***xvdivp***), *VSX Vector Multiply Double-Precision* (***xvmulp***), *VSX Vector Reciprocal Estimate Double-Precision* (***xvredp***), *VSX Vector Subtract Double-Precision* (***xvsubp***), and *VSX Vector Double-Precision Multiply-Add Arithmetic* instructions:

3. The result is placed into its respective doubleword element of VSR[XT] as a double-precision value.
4. FR, FI, and FPRF are not modified.

7.4.4 Floating-Point Underflow Exception

7.4.4.1 Definition

Underflow exception is defined separately for the enabled and disabled states:

Enabled:

Underflow occurs when the intermediate result is “Tiny”.

Disabled:

Underflow occurs when the intermediate result is “Tiny” and there is “Loss of Accuracy”.

A *tiny* result is detected before rounding, when a nonzero intermediate result computed as though both the precision and the exponent range were unbounded would be less in magnitude than the smallest normalized number.

If the intermediate result is tiny and Underflow exception is disabled (UE=0), the intermediate result is denormalized (see Section 7.3.2.4 , “Normalization and Denormalization” on page 285) and rounded (see Section 7.3.2.6 , “Rounding” on page 287) before being placed into the target VSR.

Loss of accuracy is detected when the delivered result value differs from what would have been computed were both the precision and the exponent range unbounded.

The action to be taken depends on the setting of the Underflow Exception Enable bit of the FPSCR.

7.4.4.2 Action for UE=1

When Underflow exception is enabled (UE=1) and an Underflow exception occurs, the following actions are taken:

For the *VSX Vector round and Convert Double-Precision to Single-Precision format (xscvdpsp)* instruction:

1. UX is set to 1.
2. The exponent of the normalized intermediate result is adjusted by adding 192.
3. The adjusted rounded result is placed into word element 0 of VSR[XT] as a single-precision value. The contents of word elements 1-3 of VSR[XT] are undefined.
4. FPRF is set to indicate the class and sign of the result (\pm Normalized Number).

For *VSX Scalar Add Double-Precision (xsadddp)*, *VSX Scalar Divide Double-Precision (xsdivdp)*, *VSX Scalar Multiply Double-Precision (xsmuldp)*, *VSX Scalar Reciprocal Estimate Double-Precision (xsredp)*, *VSX Scalar Subtract Double-Precision (xssubdp)*, and *VSX Scalar Double-Precision Multiply-Add Arithmetic* instructions:

1. UX is set to 1.
2. The exponent of the normalized intermediate result is adjusted by adding 1536.
3. The adjusted rounded result is placed into doubleword element 0 of VSR[XT] as a double-precision value. The contents of doubleword element 1 of VSR[XT] are undefined.
4. FPRF is set to indicate the class and sign of the result (\pm Normalized Number).

Programming Note

The FR and FI bits are provided to allow the system floating-point enabled exception error handler, when invoked because of an Underflow exception, to simulate a “trap disabled” environment. That is, the FR and FI bits allow the system floating-point enabled exception error handler to unround the result, thus allowing the result to be denormalized.

For *VSX Vector Add Double-Precision (xvadddp)*, *VSX Vector Add Single-Precision (xvaddsp)*, *VSX Vector Divide Double-Precision (xvdivdp)*, *VSX Vector Divide Single-Precision (xvdivsp)*, *VSX Vector Multiply Double-Precision (xvmuldp)*, *VSX Vector Multiply Single-Precision (xvmulsp)*, *VSX Vector Reciprocal Estimate Double-Precision (xvredp)*, *VSX Vector Reciprocal Estimate Single-Precision (xvresp)*, *VSX Vector round and Convert Double-Precision to Single-Precision format (xvcvdpsp)*, *VSX Vector Subtract Double-Precision (xvsubdp)*, *VSX Vector Subtract Single-Precision (xvsubsp)*, *VSX Vector Double-Precision Multiply-Add Arithmetic*, and *VSX Vector Single-Precision Multiply-Add Arithmetic* instructions:

1. UX is set to 1.
2. Update of VSR[XT] is suppressed for all vector elements.
3. FR, FI, and FPRF are not modified.

7.4.4.3 Action for UE=0

When Underflow exception is disabled (UE=0) and an Underflow exception occurs, the following actions are taken:

For the *VSX Vector round and Convert Double-Precision to Single-Precision format (xscvddpsp)* instruction:

1. UX is set to 1.
2. The result is placed into word element 0 of VSR[XT] as a single-precision value. The contents of word elements 1-3 of VSR[XT] are undefined.
3. FPRF is set to indicate the class and sign of the result (\pm Normalized Number, \pm Denormalized Number, or \pm Zero).

For *VSX Scalar Add Double-Precision (xsadddp)*, *VSX Scalar Divide Double-Precision (xsdivdp)*, *VSX Scalar Multiply Double-Precision (xsmuldp)*, *VSX Scalar Reciprocal Estimate Double-Precision (xsredp)*, *VSX Scalar Subtract Double-Precision (xssubdp)*, and *VSX Scalar Double-Precision Multiply-Add Arithmetic* instructions:

1. UX is set to 1.
2. The result is placed into doubleword element 0 of VSR[XT] as a double-precision value. The contents of doubleword element 1 of VSR[XT] are undefined.
3. FPRF is set to indicate the class and sign of the result (\pm Normalized Number, \pm Denormalized Number, or \pm Zero).

For *VSX Vector Add Single-Precision (xvaddsp)*, *VSX Vector Divide Single-Precision (xvdivsp)*, *VSX Vector Multiply Single-Precision (xvmulsp)*, *VSX Vector Reciprocal Estimate Single-Precision (xvresp)*, *VSX Vector round and Convert Double-Precision to Single-Precision format (xvcvddpsp)*, *VSX Vector Subtract Single-Precision (xvsubsp)*, and *VSX Vector Single-Precision Multiply-Add Arithmetic* instructions:

1. UX is set to 1.
2. The result is placed into its respective word element of VSR[XT] as a single-precision value.
3. FR, FI, and FPRF are not modified.

For *VSX Vector Add Double-Precision (xvadddp)*, *VSX Vector Divide Double-Precision (xvdivdp)*, *VSX Vector Multiply Double-Precision (xvmuldp)*, *VSX Vector Reciprocal Estimate Double-Precision (xvredp)*, *VSX Vector Subtract Double-Precision (xvsubdp)*, and *VSX Vector Double-Precision Multiply-Add Arithmetic* instructions:

1. UX is set to 1.
2. The result is placed into its respective doubleword element of VSR[XT] as a double-precision value.
3. FR, FI, and FPRF are not modified.

7.4.5 Floating-Point Inexact Exception

7.4.5.1 Definition

An Inexact exception occurs when one of two conditions occur during rounding:

1. The rounded result differs from the intermediate result assuming both the precision and the exponent range of the intermediate result to be unbounded. In this case the result is said to be inexact. (If the rounding causes an enabled Overflow exception or an enabled Underflow exception, an Inexact exception also occurs only if the significands of the rounded result and the intermediate result differ.)
2. The rounded result overflows and Overflow exception is disabled.

The action to be taken depends on the setting of the Inexact Exception Enable bit of the FPSCR.

7.4.5.2 Action for XE=1

Programming Note

In some implementations, enabling Inexact exceptions can degrade performance more than does enabling other types of floating-point exception.

When Inexact exception is enabled (XE=1) and an Inexact exception occurs, the following actions are taken:

For the *VSX Vector round and Convert Double-Precision to Single-Precision format (xscvdpssp)* instruction:

1. XX is set to 1.
2. The result is placed into word element 0 of VSR[XT] as a single-precision value. The contents of word elements 1-3 of VSR[XT] are undefined.
3. FPRF is set to indicate the class and sign of the result.

For *VSX Scalar Add Double-Precision (xsaddp)*, *VSX Scalar Subtract Double-Precision (xssubp)*, *VSX Scalar Multiply Double-Precision (xsmuldp)*, *VSX Scalar Divide Double-Precision (xsdivdp)*, *VSX Scalar Square Root Double-Precision (xssqrdp)*, *VSX Scalar Double-Precision Multiply-Add Arithmetic*, *VSX Scalar Round to Double-Precision Integer Exact using Current rounding mode (xsrdpic)*, and *VSX Scalar Convert Integer to Double-Precision* instructions:

1. XX is set to 1.
2. The result is placed into doubleword element 0 of VSR[XT]. The contents of doubleword element 1 of VSR[XT] are undefined.
3. FPRF is set to indicate the class and sign of the result.

For the *VSX Scalar truncate Double-Precision to integer and Convert to Signed Fixed-Point Word format with Saturate (xscvdpsxws)* and *VSX Scalar truncate Double-Precision to integer and Convert to Unsigned Fixed-Point Word format with Saturate (xscvdpuxws)* instructions:

1. XX is set to 1.
2. The result is placed into word element 1 of VSR[XT]. The contents of word elements 0, 2, and 3 of VSR[XT] are undefined.
3. FPRF is set to indicate the class and sign of the result.

For VSX vector floating-point operations:

1. XX is set to 1.
2. Update of VSR[XT] is suppressed for all vector elements.
3. FR, FI, and FPRF are not modified.

7.4.5.3 Action for XE=0

When Inexact exception is disabled (XE=0) and an Inexact exception occurs, the following actions are taken:

For the *VSX Vector round and Convert Double-Precision to Single-Precision format* instruction:

1. XX is set to 1.
2. The result is placed into word element 0 of VSR[XT] as a single-precision value. The contents of word elements 1-3 of VSR[XT] are undefined.
3. FPRF is set to indicate the class and sign of the result.

For VSX scalar double-precision floating-point operations:

1. XX is set to 1.
2. The result is placed into doubleword element 0 of VSR[XT] as a double-precision value. The contents of doubleword element 1 of VSR[XT] are undefined.
3. FPRF is set to indicate the class and sign of the result (\pm Normalized Number, \pm Denormalized Number, or \pm Zero).

For the *VSX Scalar truncate Floating-Point to integer and Convert to Signed Fixed-Point Word format with Saturate* instructions:

1. XX is set to 1.
2. The result is placed into word element 1 of VSR[XT] as a single-precision value. The contents of word elements 0, 2, and 3 of VSR[XT] are undefined.
3. FPRF is set to indicate the class and sign of the result.

For VSX vector single-precision floating-point operations:

1. XX is set to 1.
2. The result is placed into its respective word element of VSR[XT] as a single-precision value.
3. FR, FI, and FPRF are not modified.

For VSX vector double-precision floating-point operations:

1. XX is set to 1.
2. The result is placed into its respective doubleword element of VSR[XT] as a double-precision value.
3. FR, FI, and FPRF are not modified.

7.5 Storage Access Operations

The *VSX Storage Access* instructions compute the effective address (EA) of the storage to be accessed as described in Power ISA Book I.

7.5.1 Accessing Aligned Storage Operands

The following quadword-aligned array, AH, consists of 8 halfwords.

```
short  AW[4] = { 0x0001_0203,
                 0x0405_0607,
                 0x0809_0A0B,
                 0x0C0D_0E0F };
```

Figure 116 illustrates the big-endian storage image of array AW.

Figure 116.Big-endian storage image of array AW

Figure 117 illustrates the little-endian storage image of array AW.

Figure 117.Little-endian storage image of array AW

Figure 118 shows the result of loading that quadword into a VSR or, equivalently, shows the contents that must be in a VSR if storing that VSR is to produce the storage contents shown in Figure 116 for big-endian. Note that Figure shows the effect of loading the quadword from both big-endian storage and little-endian storage.

Figure 118.Vector-Scalar Register contents for aligned quadword Load or Store VSX Vector

7.5.2 Accessing Unaligned Storage Operands

The following array, B, consists of 5 word elements.

```
int    B[5];
B[0] = 0x01234567;
B[1] = 0x00112233;
B[2] = 0x44556677;
B[3] = 0x8899AABB;
B[4] = 0xCCDDEEFF;
```

Figure 119 illustrates both big-endian and little-endian storage images of array B.

Figure 119.Storage images of array B

Though this example shows the array starting at a quadword-aligned address, if the subject data of interest are elements 1 through 4, accessing elements 1 through 4 of array B involves an unaligned quadword storage access that spans two aligned quadwords.

Loading an Unaligned Quadword from Big-Endian Storage

Loading elements from elements 1 through 4 of B (see Figure 119) into VR[VT] involves an unaligned quadword storage access.

VSX supports word-aligned vector and scalar storage accesses using big-endian byte ordering.

Assumptions

GPR[Ra] = address of B

GPR[Rb] = 4 (index to B[1])

lxvw4x Xt,Ra,Rb

Figure 120.Process to load misaligned quadword from big-endian storage using Load VSX Vector Word*4 Indexed

Loading an Unaligned Quadword from Little-Endian Storage

Loading elements from elements 1 through 4 of B (see Figure 119) into VR[VT] involves an unaligned quadword storage access.

VSX supports word-aligned vector and scalar storage accesses using little-endian byte ordering.

Assumptions

GPR[A] = address of B

GPR[B] = 4 (index to B[1])

lxvw4x Xt,Ra,Rb

Figure 121.Process to load misaligned quadword from little-endian storage Load VSX Vector Word*4 Indexed

Storing an Unaligned Quadword to Big-Endian Storage

Storing a VSR to elements 1 through 4 of B (see Figure 119) into VR[VT] involves an unaligned quadword storage access.

VSX supports word-aligned vector and scalar storage accesses using big-endian byte ordering.

Assumptions

GPR[Ra] = address of B

GPR[Rb] = 4 (index to B[1])

stxvw4x Xs, Ra, Rb

Figure 122. Process to store misaligned quadword to big-endian storage using Store VSX Vector Word*4 Indexed

Storing an Unaligned Quadword to Little-Endian Storage

Storing a VSR to elements 1 through 4 of B (see Figure 119) into VR[VT] involves an unaligned quadword storage access.

VSX supports word-aligned vector and scalar storage accesses using little-endian byte ordering.

Assumptions

GPR[A] = address of B

GPR[B] = 4 (index to B[1])

stxvw4x Xs, Ra, Rb

Figure 123. Process to store misaligned quadword to little-endian storage Store VSX Vector Word*4 Indexed

7.5.3 Storage Access Exceptions

Storage accesses cause the system data storage error handler to be invoked if the program is not allowed to modify the target storage (*Store* only), or if the program attempts to access storage that is unavailable.

The address used for VSX storage accesses must be word-aligned to guarantee the access can be performed in hardware rather than result in an Alignment interrupt.

7.6 VSX Instruction Set Summary

7.6.1 VSX Storage Access Instructions

There are two basic forms of scalar load and scalar store instructions, word and doubleword. *VSX Scalar Load* instructions place a copy of the contents of the addressed word or doubleword in storage into the left-most word or doubleword element of the target VSR. The contents of the right-most element(s) of the target VSR are undefined. *VSX Scalar Store* instructions place a copy of the contents of the left-most word or doubleword element in the source VSR into the addressed word or doubleword in storage.

There are two basic forms of vector load and vector store instructions, a vector of 4 word elements and a vector of two doublewords. Both forms access a quadword in storage.

There is one basic form of scalar load and splat instruction, doubleword. *VSX Scalar Load and Splat* instruction places a copy of the contents of the addressed doubleword in storage into both doubleword elements of the target VSR.

7.7 VSX Instruction Descriptions

7.7.1 Instruction Description Conventions

7.7.1.1 Instruction RTL Operators

x{y}

Return bit y of x.

x{y:z}

Return bits y:z of x.

x = y

The value of y is placed into x.

x |= y

The value of y is ORed with the value x and placed into x.

~x

Return the one's complement of x.

!x

Return 1 if the contents of x are equal to 0, otherwise return 0.

x || y

Return the value of x concatenated with the value of y. For example, 0b010 || 0b111 is the same as 0b010111.

x ^ y

Return the value of x exclusive ORed with the value of y.

x ? y : z

If the value of x is true, return the value of y, otherwise return the value z.

x+y

x and y are integer values.
Return the sum of x and y.

x-y

x and y are integer values.
Return the difference of x and y.

x!=y

x and y are integer values.
Return 1 if x is not equal to y, otherwise return 0.

x<=y

x and y are integer values.
Return 1 if x is less than or equal to y, otherwise return 0.

x>=y

x and y are integer values.
Return 1 if x is greater than or equal to y, otherwise return 0.

7.7.1.2 Instruction RTL Function Calls

AddDP(x,y)

x and y are double-precision floating-point values.

If x or y is an SNaN, `vxsnan_flag` is set to 1.

If x is an Infinity and y is an Infinity of the opposite sign, `vxisi_flag` is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if y is a QNaN, return y.

Otherwise, if y is an SNaN, return y represented as a QNaN.

Otherwise, if x and y are infinities of opposite sign, return the standard QNaN.

Otherwise, return the normalized sum of x and y, having unbounded range and precision.

AddSP(x,y)

x and y are single-precision floating-point values.

If x or y is an SNaN, `vxsnan_flag` is set to 1.

If x is an Infinity and y is an Infinity of the opposite sign, `vxisi_flag` is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if y is a QNaN, return y.

Otherwise, if y is an SNaN, return y represented as a QNaN.

Otherwise, if x and y are infinities of opposite sign, return the standard QNaN.

Otherwise, return the normalized sum of x added to y, having unbounded range and precision.

ClassDP(x,y)

Return a 5-bit characterization of the double-precision floating-point number x.

```

0b10001 = Quiet NaN
0b01001 = -Infinity
0b01000 = -Normalized Number
0b11000 = -Denormalized Number
0b10010 = -Zero
0b00010 = +Zero
0b10100 = +Denormalized Number
0b00100 = +Normalized Number
0b00101 = +Infinity

```

ClassSP(x,y)

Return a 5-bit characterization of the single-precision floating-point number x.

```

0b10001 = Quiet NaN
0b01001 = -Infinity
0b01000 = -Normalized Number
0b11000 = -Denormalized Number
0b10010 = -Zero
0b00010 = +Zero
0b10100 = +Denormalized Number
0b00100 = +Normalized Number
0b00101 = +Infinity

```

CompareEQDP(x,y)

x and y are double-precision floating-point values.

If x or y is a NaN, return 0.

Otherwise, if x is equal to y, return 1.

Otherwise, return 0.

CompareEQSP(x,y)

x and y are single-precision floating-point values.

If x or y is a NaN, return 0,

Otherwise, if x is equal to y, return 1.

Otherwise, return 0.

CompareGTDP(x,y)

x and y are double-precision floating-point values.

If x or y is a NaN, return 0,

Otherwise, if x is greater than y, return 1.

Otherwise, return 0.

CompareGTSP(x,y)

x and y are single-precision floating-point values.

If x or y is a NaN, return 0.

Otherwise, if x is greater than y, return 1.

Otherwise, return 0.

CompareLTDP(x,y)

x and y are double-precision floating-point values.

If x or y is a NaN, return 0.

Otherwise, if x is less than y, return 1.

Otherwise, return 0.

CompareLTSP(x,y)

x and y are single-precision floating-point values.

If x or y is a NaN, return 0.

Otherwise, if x is less than y, return 1.

Otherwise, return 0.

ConvertDPtoSD(x)

x is a double-precision integer value.

If x is a NaN,

```

return 0x8000_0000_0000_0000,
vxcvi_flag is set to 1, and
vxsnan_flag is set to 1 if x is an SNaN.

```

Otherwise, do the following.

```

If x is greater than  $2^{63}-1$ ,
return 0x7FFF_FFFF_FFFF_FFFF and
vxcvi_flag is set to 1.

```

```

Otherwise, if x is less than  $-2^{63}$ ,
return 0x8000_0000_0000_0000 and
vxcvi_flag is set to 1.

```

Otherwise, return the value x in 64-bit signed integer format.

ConvertDPtoSW(x)

x is a double-precision integer value.

If x is a NaN,

return 0x8000_0000,
vxcvi_flag is set to 1, and
vxsnan_flag is set to 1 if x is an SNaN

Otherwise, do the following.

If x is greater than $2^{31}-1$,
return 0x7FFF_FFFF and
vxcvi_flag is set to 1.

Otherwise, if x is less than -2^{31} ,
return 0x8000_0000 and
vxcvi_flag is set to 1.

Otherwise, return the value x in 32-bit signed integer format.

ConvertDPtoUD(x)

x is a double-precision integer value.

If x is a NaN,

return 0x0000_0000_0000_0000,
vxcvi_flag is set to 1, and
vxsnan_flag is set to 1 if x is an SNaN

Otherwise, do the following.

If x is greater than $2^{64}-1$,
return 0xFFFF_FFFF_FFFF_FFFF and
vxcvi_flag is set to 1.

Otherwise, if x is less than 0,
return 0x0000_0000_0000_0000 and
vxcvi_flag is set to 1.

Otherwise, return the value x in 64-bit unsigned integer format.

ConvertDPtoUW(x)

x is a double-precision integer value.

If x is a NaN,

return 0x0000_0000,
vxcvi_flag is set to 1, and
vxsnan_flag is set to 1 if x is an SNaN

Otherwise, do the following.

If x is greater than $2^{32}-1$,
return 0xFFFF_FFFF and
vxcvi_flag is set to 1.

Otherwise, if x is less than 0,
return 0x0000_0000 and
vxcvi_flag is set to 1.

Otherwise, return the value x in 32-bit unsigned integer format.

ConvertFPtoDP(x)

Return the floating-point value x in DP format.

ConvertFPtoSP(x)

Return the floating-point value x in single-precision format.

ConvertSDtoFP(x)

x is a 64-bit signed integer value.

Return the value x converted to floating-point format having unbounded significand precision.

ConvertSPtoDP(x)

x is a single-precision floating-point value.

If x is an SNaN, vxsnan_flag is set to 1.

If x is an SNaN, return x represented as a QNaN in double-precision floating-point format.

Otherwise, if x is an QNaN, return x in double-precision floating-point format.

Otherwise, return the value x in double-precision floating-point format.

ConvertSPtoSD(x)

x is a single-precision integer value.

If x is a NaN,

return 0x8000_0000_0000_0000 and
vxcvi_flag is set to 1, and
vxsnan_flag is set to 1 if x is an SNaN

Otherwise, do the following.

If x is greater than $2^{63}-1$,
return 0x7FFF_FFFF_FFFF_FFFF and
vxcvi_flag is set to 1.

Otherwise, if x is less than -2^{63} ,
return 0x8000_0000_0000_0000 and
vxcvi_flag is set to 1.

Otherwise, return the value x in 64-bit signed integer format.

ConvertSPtoSW(x)

x is a single-precision integer value.

If x is a NaN,

return 0x8000_0000,
vxcvi_flag is set to 1, and
vxsnan_flag is set to 1 if x is an SNaN

Otherwise, do the following.

If x is greater than $2^{31}-1$,
return 0x7FFF_FFFF and
vxcvi_flag is set to 1.

Otherwise, if x is less than -2^{31} ,
return `0x8000_0000` and
`vx cvi_flag` is set to 1.

Otherwise, return the value x in 32-bit signed integer format.

ConvertSPtoUD(x)

x is a single-precision integer value.

If x is a NaN,
return `0x0000_0000_0000_0000`,
`vx cvi_flag` is set to 1, and
`vx snan_flag` is set to 1 if x is an SNaN

Otherwise, do the following.
If x is greater than $2^{64}-1$,
return `0xFFFF_FFFF_FFFF_FFFF` and
`vx cvi_flag` is set to 1.

Otherwise, if x is less than 0,
return `0x0000_0000_0000_0000` and
`vx cvi_flag` is set to 1.

Otherwise, return the value x in 64-bit unsigned integer format.

ConvertSPtoUW(x)

x is a single-precision integer value.

If x is a NaN,
return `0x0000_0000`,
`vx cvi_flag` is set to 1, and
`vx snan_flag` is set to 1 if x is an SNaN

Otherwise, do the following.
If x is greater than $2^{32}-1$,
return `0xFFFF_FFFF` and
`vx cvi_flag` is set to 1.

Otherwise, if x is less than 0,
return `0x0000_0000` and
`vx cvi_flag` is set to 1.

Otherwise, return the value x in 32-bit unsigned integer format.

ConvertSWtoFP(x)

x is a 32-bit signed integer value.

Return the value x converted to floating-point format having unbounded significand precision.

ConvertUDtoFP(x)

x is a 64-bit unsigned integer value.

Return the value x converted to floating-point format having unbounded significand precision.

ConvertUWtoFP(x)

x is a 32-bit unsigned integer value.

Return the value x converted to floating-point format having unbounded significand precision.

DivideDP(x,y)

x and y are double-precision floating-point values.

If x or y is an SNaN, `vx snan_flag` is set to 1.

If x is a Zero and y is a Zero, `vx zdz_flag` is set to 1.

If x is a finite, nonzero value and y is a Zero, `zx_flag` is set to 1.

If x is an Infinity and y is an Infinity, `vx idi_flag` is set to 1.

If x is a QNaN, return x .

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if y is a QNaN, return y .

Otherwise, if y is an SNaN, return y represented as a QNaN.

Otherwise, if x is a Zero and y is a Zero, return the standard QNaN.

Otherwise, if x is a finite, nonzero value and y is a Zero with the same sign as x , return +Infinity.

Otherwise, if x is a finite, nonzero value and y is a Zero with the opposite sign as x , return -Infinity.

Otherwise, if x is an Infinity and y is an Infinity, return the standard QNaN.

Otherwise, return the normalized quotient of x divided by y , having unbounded range and precision.

DivideSP(x,y)

x and y are single-precision floating-point values.

If x or y is an SNaN, `vxsnan_flag` is set to 1.

If x is a Zero and y is a Zero, `vxzdz_flag` is set to 1.

If x is a finite, nonzero value and y is a Zero, `zxf_flag` is set to 1.

If x is an Infinity and y is an Infinity, `vxidi_flag` is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if y is a QNaN, return y.

Otherwise, if y is an SNaN, return y represented as a QNaN.

Otherwise, if x is a Zero and y is a Zero, return the standard QNaN.

Otherwise, if x is a finite, nonzero value and y is a Zero with the same sign as x, return +Infinity.

Otherwise, if x is a finite, nonzero value and y is a Zero with the opposite sign as x, return -Infinity.

Otherwise, if x is an Infinity and y is an Infinity, return the standard QNaN.

Otherwise, return the normalized quotient of x divided by y, having unbounded range and precision.

DenormDP(x)

x is a floating-point value having unbounded range and precision.

Return the value x with its significand shifted right by a number of bits equal to the difference of the -1022 and the unbiased exponent of x, and its unbiased exponent set to -1022.

DenormSP(x)

x is a floating-point value having unbounded range and precision.

Return the value x with its significand shifted right by a number of bits equal to the difference of the -126 and the unbiased exponent of x, and its unbiased exponent set to -126.

IsInf(x)

Return 1 if x is an Infinity, otherwise return 0.

IsNaN(x)

Return 1 if x is either an SNaN or a QNaN, otherwise return 0.

IsNeg(x)

Return 1 if x is a negative, nonzero value, otherwise return 0.

IsSNaN(x)

Return 1 if x is an SNaN, otherwise return 0.

IsZero(x)

Return 1 if x is a Zero, otherwise return 0.

MaximumDP(x,y)

x and y are double-precision floating-point values.

If x or y is an SNaN, `vxsnan_flag` is set to 1.

If x is a QNaN and y is not a NaN, return y.

Otherwise, if x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if y is a QNaN, return x.

Otherwise, if y is an SNaN, return y represented as a QNaN.

Otherwise, return the greater of x and y, where +0 is considered greater than -0.

MaximumSP(x,y)

x and y are single-precision floating-point values.

If x or y is an SNaN, `vxsnan_flag` is set to 1.

If x is a QNaN and y is not a NaN, return y.

Otherwise, if x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if y is a QNaN, return x.

Otherwise, if y is an SNaN, return y represented as a QNaN.

Otherwise, return the greater of x and y, where +0 is considered greater than -0.

MEM(x,y)

Contents of a sequence of y bytes of storage. The sequence depends on the endianness of the storage access as follows.

- For big-endian storage accesses, the sequence starts with the byte at address x and ends with the byte at address $x+y-1$.
- For little-endian storage accesses, the sequence starts with the byte at address $x+y-1$ and ends with the byte at address x .

MinimumDP(x,y)

x and y are double-precision floating-point values.

If x or y is an SNaN, `vxsnan_flag` is set to 1.

If x is a QNaN and y is not a NaN, return y .

Otherwise, if x is a QNaN, return x .

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if y is a QNaN, return x .

Otherwise, if y is an SNaN, return y represented as a QNaN.

Otherwise, return the lesser of x and y , where -0 is considered less than $+0$.

MinimumSP(x,y)

x and y are single-precision floating-point values.

If x or y is an SNaN, `vxsnan_flag` is set to 1.

If x is a QNaN and y is not a NaN, return y .

Otherwise, if x is a QNaN, return x .

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if y is a QNaN, return x .

Otherwise, if y is an SNaN, return y represented as a QNaN.

Otherwise, return the lesser of x and y , where -0 is considered less than $+0$.

MultiplyAddDP(x,y,z)

x , y and z are double-precision floating-point values.

If x , y or z is an SNaN, `vxsnan_flag` is set to 1.

If x is a Zero and y is an Infinity or x is an Infinity and y is a Zero, `vximz_flag` is set to 1.

If the product of x and y is an Infinity and z is an Infinity of the opposite sign, `vxisi_flag` is set to 1.

If x is a QNaN, return x .

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if z is a QNaN, return z .

Otherwise, if z is an SNaN, return z represented as a QNaN.

Otherwise, if y is a QNaN, return y .

Otherwise, if y is an SNaN, return y represented as a QNaN.

Otherwise, if x is a Zero and y is an Infinity or x is an Infinity and y is a Zero, return the standard QNaN.

Otherwise, if the product of x and y is an Infinity, and z is an Infinity of the opposite sign, return the standard QNaN.

Otherwise, return the normalized sum of z and the product of x and y , having unbounded range and precision.

MultiplyAddSP(x,y,z)

x, y and z are single-precision floating-point values.

If x, y or z is an SNaN, `vxsnan_flag` is set to 1.

If x is a Zero and y is an Infinity, or x is an Infinity and y is a Zero, `vximz_flag` is set to 1.

If the product of x and y is an Infinity and z is an Infinity of the opposite sign, `vxisi_flag` is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if z is a QNaN, return z.

Otherwise, if z is an SNaN, return z represented as a QNaN.

Otherwise, if y is a QNaN, return y.

Otherwise, if y is an SNaN, return y represented as a QNaN.

Otherwise, if x is a Zero and y is an Infinity or x is an Infinity and y is a Zero, return the standard QNaN.

Otherwise, if the product of x and y is an Infinity, and z is an Infinity of the opposite sign, return the standard QNaN.

Otherwise, return the normalized sum of z and the product of x and y, having unbounded range and precision.

MultiplyDP(x,y)

x and y are double-precision floating-point values.

If x or y is an SNaN, `vxsnan_flag` is set to 1.

If x is a Zero and y is an Infinity, or x is an Infinity and y is a Zero, `vximz_flag` is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if y is a QNaN, return y.

Otherwise, if y is an SNaN, return y represented as a QNaN.

Otherwise, if x is a Zero and y is an Infinity or x is an Infinity and y is a Zero, return the standard QNaN.

Otherwise, return the normalized product of x and y, having unbounded range and precision.

MultiplySP(x,y)

x and y are single-precision floating-point values.

If x or y is an SNaN, `vxsnan_flag` is set to 1.

If x is a Zero and y is an Infinity, or x is an Infinity and y is a Zero, `vximz_flag` is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if y is a QNaN, return y.

Otherwise, if y is an SNaN, return y represented as a QNaN.

Otherwise, if x is a Zero and y is an Infinity or x is an Infinity and y is a Zero, return the standard QNaN.

Otherwise, return the normalized product of x and y, having unbounded range and precision.

NegateDP(x)

If the double-precision floating-point value x is a NaN, return x.

Otherwise, return the double-precision floating-point value x with its sign bit complemented.

NegateSP(x)

If the single-precision floating-point value x is a NaN, return x .

Otherwise, return the single-precision floating-point value x with its sign bit complemented.

ReciprocalEstimateDP(x)

x is a double-precision floating-point value.

If x is an SNaN, `vxsnan_flag` is set to 1.

If x is a Zero, `zx_flag` is set to 1.

If x is a QNaN, return x .

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is a Zero, return an Infinity with the sign of x .

Otherwise, if x is an Infinity, return a Zero with the sign of x .

Otherwise, return an estimate of the reciprocal of x having unbounded exponent range.

ReciprocalEstimateSP(x)

x is a single-precision floating-point value.

If x is an SNaN, `vxsnan_flag` is set to 1.

If x is a Zero, `zx_flag` is set to 1.

If x is a QNaN, return x .

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is a Zero, return an Infinity with the sign of x .

Otherwise, if x is an Infinity, return a Zero with the sign of x .

Otherwise, return an estimate of the reciprocal of x having unbounded exponent range.

ReciprocalSquareRootEstimateDP(x)

x is a double-precision floating-point value.

If x is an SNaN, `vxsnan_flag` is set to 1.

If x is a Zero, `zx_flag` is set to 1.

If x is a negative, nonzero number, `vxsqrt_flag` is set to 1.

If x is a QNaN, return x .

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is a negative, nonzero value, return the default QNaN.

Otherwise, return an estimate of the reciprocal of the square root of x having unbounded exponent range.

ReciprocalSquareRootEstimateSP(x)

x is a single-precision floating-point value.

If x is an SNaN, `vxsnan_flag` is set to 1.

If x is a Zero, `zx_flag` is set to 1.

If x is a negative, nonzero number, `vxsqrt_flag` is set to 1.

If x is a QNaN, return x .

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is a negative, nonzero value, return the default QNaN.

Otherwise, return an estimate of the reciprocal of the square root of x having unbounded exponent range.

reset_xflags()

`vxsnan_flag` is set to 0.

`vximz_flag` is set to 0.

`vxidi_flag` is set to 0.

`vxisi_flag` is set to 0.

`vxzdz_flag` is set to 0.

`vxsqrt_flag` is set to 0.

`vxcvi_flag` is set to 0.

`vxvc_flag` is set to 0.

`ox_flag` is set to 0.

`ux_flag` is set to 0.

`xx_flag` is set to 0.

`zx_flag` is set to 0.

RoundToDP(x,y)

x is a 2-bit unsigned integer specifying one of four rounding modes.

0b00 Round to Nearest Even
0b01 Round towards Zero
0b10 Round towards +Infinity
0b11 Round towards - Infinity

y is a normalized floating-point value having unbounded range and precision.

Return the value y rounded to double-precision under control of the rounding mode specified by x.

```
if IsQNaN(y) then return ConvertFpToDP(y)
if IsInf(y) then return ConvertFpToDP(y)
if IsZero(y) then return ConvertFpToDP(y)
if y < Nmin then do
  if UE=0 then do
    if x=0b00 then r ← RoundToDPNearEven( DenormDP(y) )
    if x=0b01 then r ← RoundToDPTrunc( DenormDP(y) )
    if x=0b10 then r ← RoundToDPCeil( DenormDP(y) )
    if x=0b11 then r ← RoundToDPFloor( DenormDP(y) )
    ux_flag ← xx_flag
    return(ConvertFpToDP(r))
  end
else do
  y ← Scalb(y,+1536)
  ux_flag ← 1
end
end
if x=0b00 then r ← RoundToDPNearEven(y)
if x=0b01 then r ← RoundToDPTrunc(y)
if x=0b10 then r ← RoundToDPCeil(y)
if x=0b11 then r ← RoundToDPFloor(y)

    if x=0b11 then r ← sign ? -Inf : +Nmax
    ox_flag ← 0b1
    xx_flag ← 0b1
    inc_flag ← 0bU
    return(ConvertFpToDP(r))
  end
else do
  r ← Scalb(r,-1536)
  ox_flag ← 1
end
end
return(ConvertFpToDP(r))
```

RoundToDPCeil(x)

x is a floating-point value having unbounded range and precision.

If x is a QNaN, return x.

Otherwise, if x is an Infinity, return x.

Otherwise, do the following.

Return the smallest floating-point number having unbounded exponent range but double-precision significand precision that is greater or equal in value to x.

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

RoundToDPFloor(x)

x is a floating-point value having unbounded range and precision.

If x is a QNaN, return x.

Otherwise, if x is an Infinity, return x.

Otherwise, do the following.

Return the largest floating-point number having unbounded exponent range but double-precision significand precision that is lesser or equal in value to x.

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

RoundToDPIntegerCeil(x)

x is a double-precision floating-point value.

If x is an SNaN, `vxsnan_flag` is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is an infinity, return x.

Otherwise, do the following.

Return the smallest double-precision floating-point integer value that is greater or equal in value to x.

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

RoundToDPIntegerFloor(x)

x is a double-precision floating-point value.

If x is an SNaN, `vxsnan_flag` is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is an infinity, return x.

Otherwise, do the following.

Return the largest double-precision floating-point integer value that is lesser or equal in value to x

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

RoundToDPIntegerNearAway(x)

x is a double-precision floating-point value.

If x is an SNaN, `vxsnan_flag` is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is an infinity, return x.

Otherwise, do the following.

Return the largest double-precision floating-point integer value that is lesser or equal in value to $x+0.5$ if $x>0$, or the smallest double-precision floating-point integer value that is greater or equal in value to $x-0.5$ if $x<0$.

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

RoundToDPIntegerNearEven(x)

x is a double-precision floating-point value.

If x is an SNaN, `vxsnan_flag` is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is an infinity, return x.

Otherwise, do the following.

Return the double-precision floating-point integer value that is nearest in value to x (in case of a tie, the double-precision floating-point integer value with the least-significant bit equal to 0 is used).

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

RoundToDPIntegerTrunc(x)

x is a double-precision floating-point value.

If x is an SNaN, `vxsnan_flag` is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is an infinity, return x.

Otherwise, do the following.

Return the largest double-precision floating-point integer value that is lesser or equal in value to x if $x>0$, or the smallest double-precision floating-point integer value that is greater or equal in value to x if $x<0$.

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

RoundToDPNearEven(x)

x is a floating-point value having unbounded range and precision.

If x is a QNaN, return x.

Otherwise, if x is an Infinity, return x.

Otherwise, do the following.

Return the floating-point number having unbounded exponent range but double-precision significand precision that is nearest in value to x (in case of a tie, the floating-point number having unbounded exponent range but double-precision significand precision with the least-significant bit equal to 0 is used).

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

RoundToDPTrunc(x)

x is a floating-point value having unbounded range and precision.

If x is a QNaN, return x.

Otherwise, if x is an Infinity, return x.

Otherwise, do the following.

Return the largest floating-point number having unbounded exponent range but double-precision significand precision that is lesser or equal in value to x if $x > 0$, or the smallest floating-point number having unbounded exponent range but double-precision significand precision that is greater or equal in value to x if $x < 0$.

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

RoundToSP(x,y)

x is a 2-bit unsigned integer specifying one of four rounding modes.

0b00 Round to Nearest Even
0b01 Round towards Zero
0b10 Round towards +Infinity
0b11 Round towards - Infinity

y is a normalized floating-point value having unbounded range and precision.

Return the value y rounded to single-precision under control of the rounding mode specified by x.

```
if IsQNaN(y) then return ConvertFPtoSP(y)
if IsInf(y) then return ConvertFPtoSP(y)
if IsZero(y) then return ConvertFPtoSP(y)
if y<Nmin then do
  if UE=0 then do
    if x=0b00 then r ← RoundToSPNearEven( DenormSP(y) )
    if x=0b01 then r ← RoundToSPTrunc( DenormSP(y) )
    if x=0b10 then r ← RoundToSPCeil( DenormSP(y) )
    if x=0b11 then r ← RoundToSPFloor( DenormSP(y) )
    ux_flag ← xx_flag
    return(ConvertFPtoSP(r))
  end
  else do
    y ← Scalb(y,+192)
    ux_flag ← 1
  end
end
if x=0b00 then r ← RoundToSPNearEven(y)
if x=0b01 then r ← RoundToSPTrunc(y)
if x=0b10 then r ← RoundToSPCeil(y)
if x=0b11 then r ← RoundToSPFloor(y)
if r>Nmax then do
  if OE=0 then do
    if x=0b00 then r ← sign ? -Inf : +Inf
    if x=0b01 then r ← sign ? -Nmax : +Nmax
    if x=0b10 then r ← sign ? -Nmax : +Inf
    if x=0b11 then r ← sign ? -Inf : +Nmax
    ox_flag ← 0b1
    xx_flag ← 0b1
    inc_flag ← 0bU
    return(ConvertFPtoSP(r))
  end
  else do
    r ← Scalb(r,-192)
    ox_flag ← 1
  end
end
return(ConvertFPtoSP(r))
```

RoundToSPCeil(x)

x is a floating-point value having unbounded range and precision.

If x is a QNaN, return x.

Otherwise, if x is an Infinity, return x.

Otherwise, do the following.

Return the smallest floating-point number having unbounded exponent range but single-precision significand precision that is greater or equal in value to x.

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

RoundToSPFloor(x)

x is a floating-point value having unbounded range and precision.

If x is a QNaN, return x.

Otherwise, if x is an Infinity, return x.

Otherwise, do the following.

Return the largest floating-point number having unbounded exponent range but single-precision significand precision that is lesser or equal in value to x.

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

RoundToSPIntegerCeil(x)

x is a single-precision floating-point value.

If x is an SNaN, `vxsnan_flag` is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is an infinity, return x.

Otherwise, do the following.

Return the smallest single-precision floating-point integer value that is greater or equal in value to x.

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

RoundToSPIntegerFloor(x)

x is a single-precision floating-point value.

If x is an SNaN, `vxsnan_flag` is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is an infinity, return x.

Otherwise, do the following.

Return the largest single-precision floating-point integer value that is lesser or equal in value to x.

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

RoundToSPIntegerNearAway(x)

x is a single-precision floating-point value.

If x is an SNaN, `vxsnan_flag` is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is an infinity, return x.

Otherwise, do the following.

Return x if x is a floating-point integer; otherwise return the largest single-precision floating-point integer value that is lesser or equal in value to $x+0.5$ if $x>0$, or the smallest single-precision floating-point integer value that is greater or equal in value to $x-0.5$ if $x<0$.

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

RoundToSPIntegerNearEven(x)

x is a single-precision floating-point value.

If x is an SNaN, `vxsnan_flag` is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is an infinity, return x.

Otherwise, do the following.

Return x if x is a floating-point integer; otherwise return the single-precision floating-point integer value that is nearest in value to x (in case of a tie, the single-precision floating-point integer value with the least-significant bit equal to 0 is used).

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

RoundToSPIntegerTrunc(x)

x is a single-precision floating-point value.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN, and `vxsnan_flag` is set to 1.

Otherwise, if x is an infinity, return x.

Otherwise, do the following.

Return the largest single-precision floating-point integer value that is lesser or equal in value to x if $x>0$, or the smallest single-precision floating-point integer value that is greater or equal in value to x if $x<0$.

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

RoundToSPNearEven(x)

x is a floating-point value having unbounded range and precision.

If x is a QNaN, return x.

Otherwise, if x is an Infinity, return x.

Otherwise, do the following.

Return the floating-point number having unbounded exponent range but single-precision significand precision that is nearest in value to x (in case of a tie, the floating-point number having unbounded exponent range but single-precision significand precision with the least-significant bit equal to 0 is used).

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

RoundToSPTrunc(x)

x is a floating-point value having unbounded range and precision.

If x is a QNaN, return x.

Otherwise, if x is an Infinity, return x.

Otherwise, do the following.

Return the largest floating-point number having unbounded exponent range but single-precision significand precision that is lesser or equal in value to x if $x > 0$, or the smallest single-precision floating-point number that is greater or equal in value to x if $x < 0$.

If the magnitude of the value returned is greater than x, `inc_flag` is set to 1.

If the value returned is not equal to x, `xx_flag` is set to 1.

Scalb(x,y)

x is a floating-point value having unbounded range and precision.

y is a signed integer.

Result of multiplying the floating-point value x by 2^y .

SetFX(x)

x is one of the exception flags in the FPSCR.

If the contents of x is 0, FX and x are set to 1.

SquareRootDP(x)

x is a double-precision floating-point value.

If x is an SNaN, `vxsnan_flag` is set to 1.

If x is a negative, nonzero value, `vxsqrt_flag` is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is a negative, nonzero value, return the default QNaN.

Otherwise, return the normalized square root of x, having unbounded range and precision.

SquareRootSP(x)

x is a single-precision floating-point value.

If x is an SNaN, `vxsnan_flag` is set to 1.

If x is a negative, nonzero value, `vxsqrt_flag` is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is a negative, nonzero value, return the default QNaN.

Otherwise, return the normalized square root of x, having unbounded range and precision.

Load VSX Scalar Doubleword [with Update] Indexed XX1-form

lxsdx XT,RA,RB (0x7C00_0498)

Explanation:

src1 The double-precision floating-point value in doubleword element 0 of VSR[XA].

src2 The double-precision floating-point value in doubleword element 0 of VSR[XB].

dQNaN Default quiet NaN (0x7FF8_0000_0000_0000).

NZF Nonzero finite number.

Rezd Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs).

A(x,y) Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.
Note: If $x = -y$, v is considered to be an exact-zero-difference result (Rezd).

Q(x) Return a QNaN with the payload of x.

v The intermediate result having unbounded significand precision and unbounded exponent range.

Explanation:

—	This situation cannot occur.
v	The precise intermediate result defined in the instruction having unbounded range and precision.
$\text{Den}(x)$	The value x is denormalized. The significand is shifted left by the amount of the difference between E_{min} for the target precision (that is, -1022 for double-precision, -126 for single-precision) and the unbiased exponent of x . The unbiased exponent of the denormalized value is E_{min} . The significand of the denormalized value has unbounded significand precision.
Rezd	Exact-zero-difference result. Applies only to add operations involving source operands having the same magnitude and different signs.
$\text{Rnd}(x)$	The significand of x is rounded to the target precision according to the rounding mode specified in FPSCR_{RN} . Exponent range of the rounded result is unbounded. See Section 7.3.2.6.
Nmax	Largest (in magnitude) representable normalized number in the target precision format.
Nmin	Smallest (in magnitude) representable normalized number in the target precision format.
ulp	Least significant bit in the target precision format's significand (Unit in the Last Position).
RTN	Round To Nearest, ties to Even.
RTZ	Round Toward Zero.
RTP	Round Toward +infinity.
RTM	Round Toward -infinity.

Explanation:

- The results do not depend on this condition.
- ClassFP(x) Classifies the floating-point value x as defined in Table 2, "Floating-Point Result Flags," on page 281.
- fx(x) FX is set to 1 if x=0. x is set to 1.
- β Wrap adjust, where $\beta = 2^{1536}$ for double-precision and $\beta = 2^{192}$ for single-precision.
- q The value defined in Table 46, "Floating-Point Intermediate Result Handling," on page 344, significand rounded to the target precision, unbounded exponent range.
- r The value defined in Table 46, "Floating-Point Intermediate Result Handling," on page 344, significand rounded to the target precision, bounded exponent range.
- v The precise intermediate result defined in the instruction having unbounded significand precision, unbounded exponent range.
- FI Floating-Point Fraction Inexact status flag, FPSCR_{FI}. This status flag is nonsticky.
- FR Floating-Point Fraction Rounded status flag, FPSCR_{FR}.
- OX Floating-Point Overflow exception status flag, FPSCR_{OX}.
- error() The system error handler is invoked for the trap-enabled exception if the FE0 and FE1 bits in the Machine State Register are set to any mode other than the ignore-exception mode.
- T(x) The value x is placed in element 0 of VSR[XT] in the target precision format. The contents of the remaining element(s) of VSR[XT] are undefined.
- UX Floating-Point Underflow exception status flag, FPSCR_{UX}.
- VXSNAN Floating-Point Invalid Operation Exception (NaN) status flag, FPSCR_{VXSNAN}.
- VXSQRT Floating-Point Invalid Operation Exception (Invalid Square Root) status flag, FPSCR_{VXSQRT}.
- VXIDI Floating-Point Invalid Operation Exception (Infinity ÷ Infinity) status flag, FPSCR_{VXIDI}.
- VXIMZ Floating-Point Invalid Operation Exception (Infinity × Zero) status flag, FPSCR_{VXIMZ}.
- VXISI Floating-Point Invalid Operation Exception (Infinity – Infinity) status flag, FPSCR_{VXISI}.
- VXZDZ Floating-Point Invalid Operation Exception (Zero ÷ Zero) status flag, FPSCR_{VXZDZ}.
- XX Float-Point Inexact Exception status flag, FPSCR_{XX}. The flag is a sticky version of FPSCR_{FI}. When FPSCR_{FI} is set to a new value, the new value of FPSCR_{XX} is set to the result of ORing the old value of FPSCR_{XX} with the new value of FPSCR_{FI}.
- ZX Floating-Point Zero Divide Exception status flag, FPSCR_{ZX}.

CR[BF]  ← FL || FG || FE || FU
if(vxsnan_flag) then SetFX(VXSNAN)
if(vxvc_flag)  then SetFX(VXVC)

```

Let XA be the value AX concatenated with A.
Let XB be the value BX concatenated with B.

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

src1 is compared to src2.

Zeros of same or opposite signs compare equal.
Infinities of same signs compare equal.

See Table 48, “Actions for xscmpodp - Part 1: Compare Ordered,” on page 348.

The result of the compare is placed into CR field BF and the FPCC.

If either of the operands is a NaN, either quiet or signaling, CR field BF and the FPCC are set to reflect unordered. If either of the operands is a Signaling NaN, VXSNAN is set, and Invalid Operation is disabled (VE=0), VXVC is set. If neither operand is a Signaling NaN but at least one operand is a Quiet NaN, VXVC is set.

See Table 49, “Actions for xscmpodp - Part 2: Result,” on page 348.

Explanation:

src1 The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2 The double-precision floating-point value in doubleword element 0 of VSR[XB].
NZF Nonzero finite number.
C(x,y) The floating-point value x is compared to the floating-point value y, returning one of three 4-bit results.
 0b1000 when x is greater than y
 0b0100 when x is less than y
 0b0010 when x is equal to y
cc The 4-bit result compare code.

end

```

Let XT be the value TX concatenated with T.
Let XB be the value BX concatenated with B.

Let *src* be the double-precision floating-point value in doubleword element 0 of VSR[XB].

src is rounded to single-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 46, “Floating-Point Intermediate Result Handling,” on page 344.

The result is placed into word element 0 of VSR[XT] in single-precision format.

The contents of word elements 1, 2, and 3 of VSR[XT] are undefined.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 47, “Scalar Floating-Point Final Result,” on page 345.

end

```

Let XT be the value TX concatenated with T.
Let XB be the value BX concatenated with B.

Let `src` be the double-precision floating-point value in doubleword element 0 of VSR[XB].

If `src` is a NaN, the result is the value 0x8000_0000_0000_0000 and VXCVI is set to 1. If `src` is an SNaN, VXSNAN is also set to 1.

Otherwise, `src` is rounded to a floating-point integer using the rounding mode Round Toward Zero.

If the rounded value is greater than $2^{63}-1$, the result is 0x7FFF_FFFF_FFFF_FFFF and VXCVI is set to 1.

Otherwise, if the rounded value is less than -2^{63} , the result is 0x8000_0000_0000_0000 and VXCVI is set to 1.

Otherwise, the result is the rounded value converted to 64-bit signed-integer format.

If a trap-enabled invalid operation exception occurs,

- VSR[XT] and FPRF are not modified
- FR and FI are set to 0.

Otherwise,

- The result is placed into doubleword element 0 of VSR[XT]. The contents of doubleword element 1 of VSR[XT] are undefined.

- FPRF is set to an undefined value.

- FR is set to indicate if the result was incremented when rounded.
- FI is set to indicate the result is inexact.

See Table 52.

if( ~vex_flag ) then do
  VSR[XT] ← 0xUUUU_UUUU || result || 0xUUUU_UUUU_UUUU_UUUU
  FPRF ← 0bUUUUU
  FR ← inc_flag
  FI ← xx_flag
end
else do
  FR ← 0b0
  FI ← 0b0
end

```

Let XT be the value TX concatenated with T.
Let XB be the value BX concatenated with B.

Let `src` be the double-precision floating-point value in doubleword element 0 of VSR[XB].

If `src` is a NaN, the result is the value 0x0000_0000 and VXCVI is set to 1. If `src` is an SNaN, VXSNAN is also set to 1.

Otherwise, `src` is rounded to a floating-point integer using the rounding mode Round Toward Zero.

If the rounded value is greater than $2^{32}-1$, the result is 0xFFFF_FFFF and VXCVI is set to 1.

Otherwise, if the rounded value is less than 0, the result is 0x0000_0000 and VXCVI is set to 1.

Otherwise, the result is the rounded value converted to 32-bit unsigned-integer format.

If a trap-enabled invalid operation exception occurs,

- VSR[XT] and FPRF are not modified
- FR and FI are set to 0.

Otherwise,

- The result is placed into word element 1 of VSR[XT]. The contents of word elements 0, 2, and 3 of VSR[XT] are undefined.

- FPRF is set to an undefined value.

- FR is set to indicate if the result was incremented when rounded.
- FI is set to indicate the result is inexact.

See Table 55.

Explanation:

fx(x) FX is set to 1 if x=0. x is set to 1.

error() The system error handler is invoked for the trap-enabled exception if the FE0 and FE1 bits in the Machine State Register are set to any mode other than the ignore-exception mode.

Nmin The smallest unsigned integer word value, 0 (0x0000_0000).

Nmax The largest unsigned integer word value, 2³²-1 (0xFFFF_FFFF).

src The double-precision floating-point value in doubleword element 0 of VSR[XB].

T(x) The unsigned integer word value x is placed in word element 1 of VSR[XT].
The contents of word elements 0, 2, and 3 of VSR[XT] are undefined.

Let XT be the value TX concatenated with T.

Let XA be the value AX concatenated with A.

Let XB be the value BX concatenated with B.

Let *src1* be the double-precision floating-point value in doubleword element 0 of VSR[XA].For **xsmaddadp**, do the following.

- Let *src2* be the double-precision floating-point value in doubleword element 0 of VSR[XT].
- Let *src3* be the double-precision floating-point value in doubleword element 0 of VSR[XB].

For **xsmaddmdp**, do the following.

- Let *src2* be the double-precision floating-point value in doubleword element 0 of VSR[XB].

- Let *src3* be the double-precision floating-point value in doubleword element 0 of VSR[XT].

src1 is multiplied¹ by *src3*, producing a product having unbounded range and precision.

See part 1 of Table 57.

src2 is added² to the product, producing a sum having unbounded range and precision.The sum is normalized³.

See part 2 of Table 57.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 46, “Floating-Point Intermediate Result Handling,” on page 344.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are undefined.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 47, “Scalar Floating-Point Final Result,” on page 345.

Special Registers Altered:

FPRF FR FI FX OX UX XX
VXSNAN VXISI VXIMZ

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Explanation:

src1	The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2	For <i>xsmaddadp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XT]. For <i>xsmaddmdp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XB].
src3	For <i>xsmaddadp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XB]. For <i>xsmaddmdp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XT].
dQNaN	Default quiet NaN (0x7FF8_0000_0000_0000).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
Q(x)	Return a QNaN with the payload of x.
A(x,y)	Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision. Note: If $x = -y$, v is considered to be an exact-zero-difference result (Rezd).
M(x,y)	Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
p	The intermediate product having unbounded range and precision.
v	The intermediate result having unbounded range and precision.

Explanation:

src1	The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2	The double-precision floating-point value in doubleword element 0 of VSR[XT].
NZF	Nonzero finite number.
Q(x)	Return a QNaN with the payload of x.
M(x,y)	Return the greater of floating-point value x and floating-point value y.
T(x)	The value x is placed in doubleword element 0 of VSR[XT] in double-precision format. The contents of doubleword element 1 of VSR[XT] are undefined. FPRF, FR and FI are not modified.
fx(x)	If x is equal to 0, FX is set to 1. x is set to 1.
VXSNAN	Floating-Point Invalid Operation Exception (SNaN) status flag, FPSCR _{VXSNAN} . If VE=1, update of VSR[XT] is suppressed.

Table 58. Actions for xsmaxdp

VSX Scalar Minimum Double-Precision XX3-form

xsmindp XT,XA,XB (0xF000_0540)

60	T	A	B	168	AX	BX	TX
0	6	11	16	21	29	30	31

```

XT      ← TX || T
XA      ← AX || A
XB      ← BX || B
reset_xflags()
src1    ← VSR[XA]{0:63}
src2    ← VSR[XB]{0:63}
result{0:63} ← MinimumDP(src1,src2)
if(vxsnan_flag) then SetPX(VXSNAN)
vex_flag ← VE & vxsnan_flag

if( -vex_flag ) then do
    VSR[XT] ← result || 0xUUUU_UUUU_UUUU_UUUU
end
    
```

Let XT be the value TX concatenated with T.
 Let XA be the value AX concatenated with A.
 Let XB be the value BX concatenated with B.

Let *src1* be the double-precision floating-point value in doubleword element 0 of VSR[XA].

Let *src2* be the double-precision floating-point value in doubleword element 0 of VSR[XB].

If *src1* is less than *src2*, *src1* is placed into doubleword element 0 of VSR[XT] in double-precision format. Otherwise, *src2* is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are undefined.

The minimum of +0 and -0 is -0. The minimum of a QNaN and any value is that value. The minimum of any value and an SNaN is that SNaN converted to a QNaN.

FPRF, FR and FI are not modified.

If a trap-enabled invalid operation exception occurs, VSR[XT] is not modified.

See Table 59.

  FI ← 0b0
end

```

Let XT be the value TX concatenated with T.
 Let XA be the value AX concatenated with A.
 Let XB be the value BX concatenated with B.

Let *src1* be the double-precision floating-point value in doubleword element 0 of VSR[XA].

For *xsmsubadp*, do the following.

- Let *src2* be the double-precision floating-point value in doubleword element 0 of VSR[XT].
- Let *src3* be the double-precision floating-point value in doubleword element 0 of VSR[XB].

For *xsmsubmdp*, do the following.

- Let *src2* be the double-precision floating-point value in doubleword element 0 of VSR[XB].
- Let *src3* be the double-precision floating-point value in doubleword element 0 of VSR[XT].

src1 is multiplied¹ by *src3*, producing a product having unbounded range and precision.

See part 1 of Table 60.

src2 is negated and added² to the product, producing a sum having unbounded range and precision.

The result, having unbounded range and precision, is normalized³.

See part 2 of Table 60.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 46, “Floating-Point Intermediate Result Handling,” on page 344.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are undefined.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 47, “Scalar Floating-Point Final Result,” on page 345.

Special Registers Altered:

```

FPRF FR FI FX OX UX XX
VXSNAN VXISI VXIMZ

```

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Let XT be the value TX concatenated with T.
 Let XA be the value AX concatenated with A.
 Let XB be the value BX concatenated with B.

Let *src1* be the double-precision floating-point value in doubleword element 0 of VSR[XA].

For **xsnmaddadp**, do the following.

- Let *src2* be the double-precision floating-point value in doubleword element 0 of VSR[XT].
- Let *src3* be the double-precision floating-point value in doubleword element 0 of VSR[XB].

For **xsnmaddmdp**, do the following.

- Let *src2* be the double-precision floating-point value in doubleword element 0 of VSR[XB].

- Let *src3* be the double-precision floating-point value in doubleword element 0 of VSR[XT].

src1 is multiplied¹ by *src3*, producing a product having unbounded range and precision.

See part 1 of Table 62.

src2 is added² to the product, producing a sum having unbounded range and precision.

The sum is normalized³.

See part 2 of Table 62.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 46, “Floating-Point Intermediate Result Handling,” on page 344.

The result is negated and placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are undefined.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “Scalar Floating-Point Final Result with Negation,” on page 381.

Special Registers Altered:

FPRF FR FI FX OX UX XX
 VXSNAN VXISI VXIMZ

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Explanation:

src1 The double-precision floating-point value in doubleword element 0 of VSR[XA].

src2 For *xsnmaddadp*, the double-precision floating-point value in doubleword element 0 of VSR[XT]. For *xsnmaddmdp*, the double-precision floating-point value in doubleword element 0 of VSR[XB].

src3 For *xsnmaddadp*, the double-precision floating-point value in doubleword element 0 of VSR[XB]. For *xsnmaddmdp*, the double-precision floating-point value in doubleword element 0 of VSR[XT].

dQNaN Default quiet NaN (0x7FF8_0000_0000_0000).

NZF Nonzero finite number.

Rezd Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.

Q(x) Return a QNaN with the payload of x.

A(x,y) Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.
Note: If $x = -y$, v is considered to be an exact-zero-difference result (Rezd).

M(x,y) Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.

p The intermediate product having unbounded range and precision.

v The intermediate result having unbounded range and precision.

```

Let XT be the value TX concatenated with T.
 Let XA be the value AX concatenated with A.
 Let XB be the value BX concatenated with B.

Let `src1` be the double-precision floating-point value in doubleword element 0 of VSR[XA].

For `xsnmsubadp`, do the following.

- Let `src2` be the double-precision floating-point value in doubleword element 0 of VSR[XT].
- Let `src3` be the double-precision floating-point value in doubleword element 0 of VSR[XB].

For `xsnmsubmdp`, do the following.

- Let `src2` be the double-precision floating-point value in doubleword element 0 of VSR[XB].
- Let `src3` be the double-precision floating-point value in doubleword element 0 of VSR[XT].

`src1` is multiplied¹ by `src3`, producing a product having unbounded range and precision.

See part 1 of Table 64.

`src2` is negated and added² to the product, producing a sum having unbounded range and precision.

The sum is normalized³.

See part 2 of Table 64.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 46, “Floating-Point Intermediate Result Handling,” on page 344.

The result is negated and placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are undefined.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “Scalar Floating-Point Final Result with Negation,” on page 381.

Explanation:

src1	The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2	For <i>xsnmsubadp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XT]. For <i>xsnmsubmdp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XB].
src3	For <i>xsnmsubadp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XB]. For <i>xsnmsubmdp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XT].
dQNaN	Default quiet NaN (0x7FF8_0000_0000_0000).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
Q(x)	Return a QNaN with the payload of x.
S(x,y)	Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision. Note: If x = y, v is considered to be an exact-zero-difference result (Rezd).
M(x,y)	Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
p	The intermediate product having unbounded range and precision.
v	The intermediate result having unbounded range and precision.

Table 64. Actions for xsnmsub(al)mdp

VSX Scalar Round to Double-Precision Integer using round toward -Infinity XX2-form

xsrddpim XT,XB (0xF000_01E4)

```

XT ← TX || T
XB ← BX || B
reset_xflags()
result{0:63} ← RoundToDPIntegerFloor(VSR[XB]{0:63})
if(vxsnan_flag) then SetFX(VXSNAN)
FR ← 0b0
FI ← 0b0
vex_flag ← VE & vxsnan_flag

if( ~vex_flag ) then do
  VSR[XT] ← result || 0xUUUU_UUUU_UUUU_UUUU
  FPRF ← ClassDP(result)
end
    
```

Let XT be the value TX concatenated with T.
Let XB be the value BX concatenated with B.

Let src be the double-precision floating-point value in doubleword element 0 of VSR[XB].

src is rounded to an integer using the rounding mode Round toward -Infinity.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are undefined.

FPRF is set to the class and sign of the result. FR is set to 0. FI is set to 0.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

Special Registers Altered:

end

```

Let XT be the value TX concatenated with T.
Let XB be the value BX concatenated with B.

Let *src* be the double-precision floating-point value in doubleword element 0 of VSR[XB].

A double-precision floating-point estimate of the reciprocal of *src* is placed into doubleword element 0 of VSR[XT] in double-precision format.

Unless the reciprocal of *src* would be a zero, an infinity, or a QNaN, the estimate has a relative error in precision no greater than one part in 16384 of the reciprocal of *src*. That is,

$$\left| \frac{\text{estimate} - \frac{1}{\text{src}}}{\frac{1}{\text{src}}} \right| \leq \frac{1}{16384}$$

Operation with various special values of the operand is summarized below.

Source Value	Result	Exception
–Infinity	–Zero	None
–Zero	–Infinity ¹	ZX
+Zero	+Infinity ¹	ZX
+Infinity	+Zero	None
SNaN	QNaN ²	VXSNAN
QNaN	QNaN	None

1. No result if ZE=1.
2. No result if VE=1.

The contents of doubleword element 1 of VSR[XT] are undefined.

FPRF is set to the class and sign of the result. FR is set to an undefined value. FI is set to an undefined value.

If a trap-enabled invalid operation exception or a trap-enabled zero divide exception occurs, VSR[XT] and FPRF are not modified.

The results of executing this instruction is permitted to vary between implementations, and between different executions on the same implementation.

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Explanation:

src1	The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2	The double-precision floating-point value in doubleword element 0 of VSR[XB].
dQNaN	Default quiet NaN (0x7FF8_0000_0000_0000).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs).
S(x,y)	The floating-point value y is negated and then added to the floating-point value x.
S(x,y)	Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision. Note: If x = y, v is considered to be an exact-zero-difference result (Rezd).
Q(x)	Return a QNaN with the payload of x.
v	The intermediate result having unbounded significand precision and unbounded exponent range.

Let XA be the value AX concatenated with A.
Let XB be the value BX concatenated with B.

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

Let e_a be the unbiased exponent of src1.

Let e_b be the unbiased exponent of src2.

fe_flag is set to 1 for any of the following conditions.

- src1 is a NaN or an infinity.
- src2 is a zero, a NaN, or an infinity.
- e_b is less than or equal to -1022.
- e_b is greater than or equal to 1021.
- src1 is not a zero and the difference, e_a - e_b, is greater than or equal to 1023.
- src1 is not a zero and the difference, e_a - e_b, is less than or equal to -1021.
- src1 is not a zero and e_a is less than or equal to -970

Otherwise fe_flag is set to 0.

fg_flag is set to 1 for any of the following conditions.

- src1 is an infinity.
- src2 is a zero, an infinity, or a denormalized value.

Otherwise fg_flag is set to 0.

CR field BF is set to the value 0b1 || fg_flag || fe_flag || 0b0.

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Let XT be the value TX concatenated with T.
 Let XA be the value AX concatenated with A.
 Let XB be the value BX concatenated with B.

For each vector element *i* from 0 to 3, do the following.
 Let *src1* be the single-precision floating-point operand in word element *i* of VSR[XA].

Let *src2* be the single-precision floating-point operand in word element *i* of VSR[XB].

src2 is added¹ to *src1*, producing a sum having unbounded range and precision.

The sum is normalized².

See Table 69.

The intermediate result is rounded to single-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 46, “Floating-Point Intermediate Result Handling,” on page 344.

The result is placed into word element *i* of VSR[XT] in single-precision format.

See Table 68, “Vector Floating-Point Final Result,” on page 400.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Explanation:

src1	The single-precision floating-point value in word element i of VSR[XA] (where $i \in \{0, 1, 2, 3\}$).
src2	The single-precision floating-point value in word element i of VSR[XB] (where $i \in \{0, 1, 2, 3\}$).
dQNaN	Default quiet NaN ($0 \times 7\text{FC}0_0000$).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs).
A(x,y)	Return the normalized sum of floating-point value x and floating-point value y , having unbounded range and precision. Note: If $x = -y$, v is considered to be an exact-zero-difference result (Rezd).
Q(x)	Return a QNaN with the payload of x .
v	The intermediate result having unbounded significand precision and unbounded exponent range.

Let XT be the value TX concatenated with T.
 Let XA be the value AX concatenated with A.
 Let XB be the value BX concatenated with B.

For each vector element i from 0 to 1, do the following.
 Let src1 be the double-precision floating-point operand in doubleword element i of VSR[XA].

Let src2 be the double-precision floating-point operand in doubleword element i of VSR[XB].

src1 is compared to src2.

The contents of doubleword element i of VSR[XT] are set to all 1s if src1 is equal to src2, and is set to all 0s otherwise.

A NaN input causes the comparison to return false for that element.

Two zero inputs of same or different signs return true for that element.

Two infinity inputs of same signs return true for that element.

If Rc=1, CR Field 6 is set as follows.

- Bit 0 of CR[6] is set to indicate all vector elements compared true.
- Bit 1 of CR[6] is set to 0.
- Bit 2 of CR[6] is set to indicate all vector elements compared false.
- Bit 3 of CR[6] is set to 0.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT] and the contents of CR[6] are undefined if Rc is equal to 1.

 Let *src1* be the single-precision floating-point operand in word element *i* of VSR[XA].

Let *src2* be the single-precision floating-point operand in word element *i* of VSR[XB].

src1 is compared to *src2*.

The contents of word element *i* of VSR[XT] are set to all 1s if *src1* is greater than *src2*, and is set to all 0s otherwise.

A NaN input causes the comparison to return false for that element.

Two zero inputs of same or different signs return false for that element.

If Rc=1, CR Field 6 is set as follows.

- Bit 0 of CR[6] is set to indicate all vector elements compared true.
- Bit 1 of CR[6] is set to 0.
- Bit 2 of CR[6] is set to indicate all vector elements compared false.
- Bit 3 of CR[6] is set to 0.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT] and the contents of CR[6] are undefined if Rc is equal to 1.

```

if(ex_flag = 0) then VSR[XT] ← result

Let XT be the value TX concatenated with T.

Let XB be the value BX concatenated with B.

For each vector element *i* from 0 to 1, do the following.

Let *src* be the single-precision floating-point operand in word element *i*×2 of VSR[XB].

If *src* is a NaN, the result is the value 0x8000_0000_0000_0000 and VXCVI is set to 1. If *src* is an SNaN, VXSNAN is also set to 1.

Otherwise, *src* is rounded to a floating-point integer using the rounding mode Round Toward Zero.

If the rounded value is greater than $2^{63}-1$, the result is 0x7FFF_FFFF_FFFF_FFFF and VXCVI is set to 1.

Otherwise, if the rounded value is less than -2^{63} , the result is 0x8000_0000_0000_0000 and VXCVI is set to 1.

Otherwise, the result is the rounded value converted to 64-bit signed-integer format.

The result is placed into doubleword element *i* of VSR[XT].

See Table 73.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

Let *src1* be the double-precision floating-point operand in doubleword element *i* of VSR[XA].

For **xvmaddadp**, do the following.

- Let *src2* be the double-precision floating-point operand in doubleword element *i* of VSR[XT].
- Let *src3* be the double-precision floating-point operand in doubleword element *i* of VSR[XB].

For **xvmaddmdp**, do the following.

- Let *src2* be the double-precision floating-point operand in doubleword element *i* of VSR[XB].
- Let *src3* be the double-precision floating-point operand in doubleword element *i* of VSR[XT].

src1 is multiplied¹ by *src3*, producing a product having unbounded range and precision.

See part 1 of Table 80.

src2 is added² to the product, producing a sum having unbounded range and precision.

The sum is normalized³.

See part 2 of Table 80.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 46, "Floating-Point Intermediate Result Handling," on page 344.

The result is placed into doubleword element *i* of VSR[XT] in double-precision format.

See Table 68, "Vector Floating-Point Final Result," on page 400.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

Special Registers Altered:

FX OX UX XX VXSNAN VXISI VXIMZ

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.

2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.

3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Explanation:

src1	The double-precision floating-point value in doubleword element i of VSR[XA] (where $i \in \{0, 1\}$).
src2	For <i>xvmaddadp</i> , the double-precision floating-point value in doubleword element i of VSR[XT] (where $i \in \{0, 1\}$). For <i>xvmaddmdp</i> , the double-precision floating-point value in doubleword element i of VSR[XB] (where $i \in \{0, 1\}$).
src3	For <i>xvmaddadp</i> , the double-precision floating-point value in doubleword element i of VSR[XB] (where $i \in \{0, 1\}$). For <i>xvmaddmdp</i> , the double-precision floating-point value in doubleword element i of VSR[XT] (where $i \in \{0, 1\}$).
dQNaN	Default quiet NaN (0x7FF8_0000_0000_0000).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
Q(x)	Return a QNaN with the payload of x .
A(x,y)	Return the normalized sum of floating-point value x and floating-point value y , having unbounded range and precision. Note: If $x = -y$, v is considered to be an exact-zero-difference result (Rezd).
M(x,y)	Return the normalized product of floating-point value x and floating-point value y , having unbounded range and precision.
p	The intermediate product having unbounded range and precision.
v	The intermediate result having unbounded range and precision.

Let `XT` be the value `TX` concatenated with `T`.
 Let `XA` be the value `AX` concatenated with `A`.
 Let `XB` be the value `BX` concatenated with `B`.

For each vector element `i` from 0 to 3, do the following.
 Let `src1` be the single-precision floating-point operand in word element `i` of `VSR[XA]`.

For `xvmaddasp`, do the following.

- Let `src2` be the single-precision floating-point operand in word element `i` of `VSR[XT]`.
- Let `src3` be the single-precision floating-point operand in word element `i` of `VSR[XB]`.

For `xvmaddmsp`, do the following.

- Let `src2` be the single-precision floating-point operand in word element `i` of `VSR[XB]`.
- Let `src3` be the single-precision floating-point operand in word element `i` of `VSR[XT]`.

`src1` is multiplied¹ by `src3`, producing a product having unbounded range and precision.

See part 1 of Table 81.

`src2` is added² to the product, producing a sum having unbounded range and precision.

The sum is normalized³.

See part 2 of Table 81.

The intermediate result is rounded to single-precision using the rounding mode specified by the Floating-Point Rounding Control field `RN` of the `FPSCR`.

See Table 46, “Floating-Point Intermediate Result Handling,” on page 344.

The result is placed into word element `i` of `VSR[XT]` in single-precision format.

See Table 68, “Vector Floating-Point Final Result,” on page 400.

If a trap-enabled exception occurs in any element of the vector, no results are written to `VSR[XT]`.

Explanation:

src1 The single-precision floating-point value in word element i of VSR[XA] (where $i \in \{0, 1, 2, 3\}$).

src2 For *xvmaddasp*, the single-precision floating-point value in word element i of VSR[XT] (where $i \in \{0, 1, 2, 3\}$). For *xvmaddmsp*, the single-precision floating-point value in word element i of VSR[XB] (where $i \in \{0, 1, 2, 3\}$).

src3 For *xvmaddasp*, the single-precision floating-point value in word element i of VSR[XB] (where $i \in \{0, 1, 2, 3\}$). For *xvmaddmsp*, the single-precision floating-point value in word element i of VSR[XT] (where $i \in \{0, 1, 2, 3\}$).

dQNaN Default quiet NaN (0x7FC0_0000).

NZF Nonzero finite number.

Rezd Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.

Q(x) Return a QNaN with the payload of x.

A(x,y) Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.
Note: If $x = -y$, v is considered to be an exact-zero-difference result (Rezd).

M(x,y) Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.

p The intermediate product having unbounded range and precision.

v The intermediate result having unbounded range and precision.

Table 81. Actions for xvmadd(alm)sp

VSX Vector Maximum Double-Precision XX3-form

xvmaxdp XT,XA,XB (0xF000_0700)

60	T	A	B	224	AX	BX	TX
0	6	11	16	21	29	30	31

XT ← TX || T

XA ← AX || A

XB ← BX || B

ex_flag ← 0b0

```
do i=0 to 127 by 64
  reset_xflags()
  src1 ← VSR[XA]{i:i+63}
  src2 ← VSR[XB]{i:i+63}
  result{i:i+63} ← MaximumDP(src1,src2)
  if(vxsnan_flag) then SetFX(VXSNaN)
  ex_flag ← ex_flag | (VE & vxsnan_flag)
end
```

if(ex_flag = 0) then VSR[XT] ← result

Let XT be the value TX concatenated with T.

Let XA be the value AX concatenated with A.

Let XB be the value BX concatenated with B.

For each vector element *i* from 0 to 1, do the following.

Let *src1* be the double-precision floating-point operand in doubleword element *i* of VSR[XA].

Let *src2* be the double-precision floating-point operand in doubleword element *i* of VSR[XB].

If *src1* is greater than *src2*, *src1* is placed into doubleword element *i* of VSR[XT] in double-precision format. Otherwise, *src2* is placed into doubleword element *i* of VSR[XT] in double-precision format.

The maximum of +0 and -0 is +0. The maximum of a QNaN and any value is that value. The maximum of any value and an SNaN when VE=0 is that SNaN converted to a QNaN.

See Table 82.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

Let XT be the value TX concatenated with T.
Let XA be the value AX concatenated with A.
Let XB be the value BX concatenated with B.

For each vector element *i* from 0 to 1, do the following.
Let `src1` be the double-precision floating-point operand in doubleword element *i* of `VSR[XA]`.

For `xvmsubadp`, do the following.

- Let `src2` be the double-precision floating-point operand in doubleword element *i* of `VSR[XT]`.
- Let `src3` be the double-precision floating-point operand in doubleword element *i* of `VSR[XB]`.

For `xvmsubmdp`, do the following.

- Let `src2` be the double-precision floating-point operand in doubleword element *i* of `VSR[XB]`.
- Let `src3` be the double-precision floating-point operand in doubleword element *i* of `VSR[XT]`.

`src1` is multiplied¹ by `src3`, producing a product having unbounded range and precision.

See part 1 of Table 86.

`src2` is negated and added² to the product, producing a sum having unbounded range and precision.

The sum is normalized³.

See part 2 of Table 86.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 46, "Floating-Point Intermediate Result Handling," on page 344.

The result is placed into doubleword element *i* of `VSR[XT]` in double-precision format.

See Table 68, "Vector Floating-Point Final Result," on page 400.

If a trap-enabled exception occurs in any element of the vector, no results are written to `VSR[XT]`.

Special Registers Altered:

FX OX UX XX VXSNAN VXISI VXIMZ

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Explanation:

src1	The double-precision floating-point value in doubleword element i of $\text{VSR}[\text{XA}]$ (where $i \in \{0, 1\}$).
src2	For <i>xvmsubadp</i> , the double-precision floating-point value in doubleword element i of $\text{VSR}[\text{XT}]$ (where $i \in \{0, 1\}$). For <i>xvmsubmdp</i> , the double-precision floating-point value in doubleword element i of $\text{VSR}[\text{XB}]$ (where $i \in \{0, 1\}$).
src3	For <i>xvmsubadp</i> , the double-precision floating-point value in doubleword element i of $\text{VSR}[\text{XB}]$ (where $i \in \{0, 1\}$). For <i>xvmsubmdp</i> , the double-precision floating-point value in doubleword element i of $\text{VSR}[\text{XT}]$ (where $i \in \{0, 1\}$).
dQNaN	Default quiet NaN ($0 \times 7\text{FF}8_0000_0000_0000$).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
Q(x)	Return a QNaN with the payload of x .
S(x,y)	Return the normalized sum of floating-point value x and negated floating-point value y , having unbounded range and precision. Note: If $x = y$, v is considered to be an exact-zero-difference result (Rezd).
M(x,y)	Return the normalized product of floating-point value x and floating-point value y , having unbounded range and precision.
p	The intermediate product having unbounded range and precision.
v	The intermediate result having unbounded range and precision.

Let XT be the value TX concatenated with T.
 Let XA be the value AX concatenated with A.
 Let XB be the value BX concatenated with B.

For each vector element *i* from 0 to 3, do the following.
 Let *src1* be the single-precision floating-point operand in word element *i* of VSR[XA].

- For *xvmsubasp*, do the following.
- Let *src2* be the single-precision floating-point operand in word element *i* of VSR[XT].
 - Let *src3* be the single-precision floating-point operand in word element *i* of VSR[XB].

For *xvmsubmsp*, do the following.

- Let *src2* be the single-precision floating-point operand in word element *i* of VSR[XB].
- Let *src3* be the single-precision floating-point operand in word element *i* of VSR[XT].

src1 is multiplied¹ by *src3*, producing a product having unbounded range and precision.

See part 1 of Table 87.

src2 is negated and added² to the product, producing a sum having unbounded range and precision.

The sum is normalized³.

See part 2 of Table 87.

The intermediate result is rounded to single-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 46, “Floating-Point Intermediate Result Handling,” on page 344.

The result is placed into word element *i* of VSR[XT] in single-precision format.

See Table 68, “Vector Floating-Point Final Result,” on page 400.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

Special Registers Altered:

FX OX UX XX VXSNAN VXISI VXIMZ

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Explanation:

src1	The single-precision floating-point value in word element i of VSR[XA] (where $i \in \{0, 1, 2, 3\}$).
src2	The single-precision floating-point value in word element i of VSR[XB] (where $i \in \{0, 1, 2, 3\}$).
dQNaN	Default quiet NaN ($0 \times 7FC0_0000$).
NZF	Nonzero finite number.
$M(x, y)$	Return the normalized product of floating-point value x and floating-point value y , having unbounded range and precision.
$Q(x)$	Return a QNaN with the payload of x .
v	The intermediate result having unbounded significand precision and unbounded exponent range.

```

Let XT be the value TX concatenated with T.

Let XA be the value AX concatenated with A.

Let XB be the value BX concatenated with B.

For each vector element *i* from 0 to 1, do the following.

Let *src1* be the double-precision floating-point operand in doubleword element *i* of VSR[XA].

For *xvnmaddadp*, do the following.

- Let *src2* be the double-precision floating-point operand in doubleword element *i* of VSR[XT].
- Let *src3* be the double-precision floating-point operand in doubleword element *i* of VSR[XB].

For *xvnmaddmdp*, do the following.

- Let *src2* be the double-precision floating-point operand in doubleword element *i* of VSR[XB].
- Let *src3* be the double-precision floating-point operand in doubleword element *i* of VSR[XT].

src1 is multiplied¹ by *src3*, producing a product having unbounded range and precision.

See part 1 of Table 90.

src2 is added² to the product, producing a sum having unbounded range and precision.

The sum is normalized³.

See part 2 of Table 90.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 46, “Floating-Point Intermediate Result Handling,” on page 344.

The result is negated and placed into doubleword element *i* of VSR[XT] in double-precision format.

See Table 91, “Vector Floating-Point Final Result with Negation,” on page 466.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

Special Registers Altered:

FX OX UX XX VXSNAN VXISI VXIMZ

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.

2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.

3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Explanation:

src1	The double-precision floating-point value in doubleword element i of $\text{VSR}[\text{XA}]$ (where $i \in \{0, 1\}$).
src2	For <i>xvnmaddadp</i> , the double-precision floating-point value in doubleword element i of $\text{VSR}[\text{XT}]$ (where $i \in \{0, 1\}$). For <i>xvnmaddmdp</i> , the double-precision floating-point value in doubleword element i of $\text{VSR}[\text{XB}]$ (where $i \in \{0, 1\}$).
src3	For <i>xvnmaddadp</i> , the double-precision floating-point value in doubleword element i of $\text{VSR}[\text{XB}]$ (where $i \in \{0, 1\}$). For <i>xvnmaddmdp</i> , the double-precision floating-point value in doubleword element i of $\text{VSR}[\text{XT}]$ (where $i \in \{0, 1\}$).
dQNaN	Default quiet NaN ($0 \times 7\text{FF}8_0000_0000_0000$).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
Q(x)	Return a QNaN with the payload of x .
A(x,y)	Return the normalized sum of floating-point value x and floating-point value y , having unbounded range and precision. Note: If $x = -y$, v is considered to be an exact-zero-difference result (Rezd).
M(x,y)	Return the product of floating-point value x and floating-point value y , having unbounded range and precision.
p	The intermediate product having unbounded range and precision.
v	The intermediate result having unbounded range and precision.

	-	1	-	-	-	-	-	-	-	-	yes	yes	fx(OX), fx(XX), error()

Explanation:

- The results do not depend on this condition.
- fx(x) FX is set to 1 if x=0. x is set to 1.
- q The value defined in Table 46, "Floating-Point Intermediate Result Handling," on page 344, significand rounded to the target precision, unbounded exponent range.
- r The value defined in Table 46, "Floating-Point Intermediate Result Handling," on page 344, significand rounded to the target precision, bounded exponent range.
- v The precise intermediate result defined in the instruction having unbounded significand precision, unbounded exponent range.
- FI Floating-Point Fraction Inexact status flag, FPSCR_{FI}. This status flag is nonsticky.
- FR Floating-Point Fraction Rounded status flag, FPSCR_{FR}.
- OX Floating-Point Overflow Exception status flag, FPSCR_{OX}.
- error() The system error handler is invoked for the trap-enabled exception if the FE0 and FE1 bits in the Machine State Register are set to any mode other than the ignore-exception mode. Update of the target VSR is suppressed for all vector elements.
- N(x) The value x is negated by complementing the sign bit of x.
- T(x) The value x is placed in element i of VSR[XT] in the target precision format (where i ∈ {0,1} for results with 64-bit elements, and i ∈ {0,1,3,4}) for results with 32-bit elements).
- UX Floating-Point Underflow Exception status flag, FPSCR_{UX}
- VXSNAN Floating-Point Invalid Operation Exception (NaN) status flag, FPSCR_{VXSNAN}.
- VXIMZ Floating-Point Invalid Operation Exception (Infinity × Zero) status flag, FPSCR_{VXIMZ}.
- VXISI Floating-Point Invalid Operation Exception (Infinity – Infinity) status flag, FPSCR_{VXISI}.
- XX Float-Point Inexact Exception status flag, FPSCR_{XX}. The flag is a sticky version of FPSCR_{FI}. When FPSCR_{FI} is set to a new value, the new value of FPSCR_{XX} is set to the result of ORing the old value of FPSCR_{XX} with the new value of FPSCR_{FI}.

	-	-	1	-	-	-	-	-	yes	-	no	-	fx(UX), error()
	-	-	1	-	-	-	-	-	yes	-	yes	no	fx(UX), fx(XX), error()
	-	-	1	-	-	-	-	-	yes	-	yes	yes	fx(UX), fx(XX), error()

Explanation:

- The results do not depend on this condition.
- fx(x) FX is set to 1 if x=0. x is set to 1.
- q The value defined in Table 46, “Floating-Point Intermediate Result Handling,” on page 344, significand rounded to the target precision, unbounded exponent range.
- r The value defined in Table 46, “Floating-Point Intermediate Result Handling,” on page 344, significand rounded to the target precision, bounded exponent range.
- v The precise intermediate result defined in the instruction having unbounded significand precision, unbounded exponent range.
- FI Floating-Point Fraction Inexact status flag, FPSCR_{FI}. This status flag is nonsticky.
- FR Floating-Point Fraction Rounded status flag, FPSCR_{FR}.
- OX Floating-Point Overflow Exception status flag, FPSCR_{OX}.
- error() The system error handler is invoked for the trap-enabled exception if the FE0 and FE1 bits in the Machine State Register are set to any mode other than the ignore-exception mode. Update of the target VSR is suppressed for all vector elements.
- N(x) The value x is negated by complementing the sign bit of x.
- T(x) The value x is placed in element i of VSR[XT] in the target precision format (where i ∈ {0,1} for results with 64-bit elements, and i ∈ {0,1,3,4} for results with 32-bit elements).
- UX Floating-Point Underflow Exception status flag, FPSCR_{UX}
- VXSNAN Floating-Point Invalid Operation Exception (SNaN) status flag, FPSCR_{VXSNAN}.
- VXIMZ Floating-Point Invalid Operation Exception (Infinity × Zero) status flag, FPSCR_{VXIMZ}.
- VXISI Floating-Point Invalid Operation Exception (Infinity – Infinity) status flag, FPSCR_{VXISI}.
- XX Float-Point Inexact Exception status flag, FPSCR_{XX}. The flag is a sticky version of FPSCR_{FI}. When FPSCR_{FI} is set to a new value, the new value of FPSCR_{XX} is set to the result of ORing the old value of FPSCR_{XX} with the new value of FPSCR_{FI}.

Let XT be the value TX concatenated with T.
 Let XA be the value AX concatenated with A.
 Let XB be the value BX concatenated with B.

For each vector element *i* from 0 to 3, do the following.
 Let `src1` be the single-precision floating-point operand in word element *i* of VSR[XA].

For `xvnmaddasp`, do the following.

- Let `src2` be the single-precision floating-point operand in word element *i* of VSR[XT].
- Let `src3` be the single-precision floating-point operand in word element *i* of VSR[XB].

For `xvnmaddmsp`, do the following.

- Let `src2` be the single-precision floating-point operand in word element *i* of VSR[XB].
- Let `src3` be the single-precision floating-point operand in word element *i* of VSR[XT].

`src1` is multiplied¹ by `src3`, producing a product having unbounded range and precision.

See part 1 of Table 92.

`src2` is added² to the product, producing a sum having unbounded range and precision.

The sum is normalized³.

See part 2 of Table 92.

The intermediate result is rounded to single-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 46, “Floating-Point Intermediate Result Handling,” on page 344.

The result is negated and placed into word element *i* of VSR[XT] in single-precision format.

See Table 91, “Vector Floating-Point Final Result with Negation,” on page 466.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

Special Registers Altered:

FX OX UX XX VXSNAN VXISI VXIMZ

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Explanation:

src1 The single-precision floating-point value in word element i of VSR[XA] (where $i \in \{0, 1, 2, 3\}$).

src2 For *xvnmaddasp*, the single-precision floating-point value in word element i of VSR[XT] (where $i \in \{0, 1, 2, 3\}$). For *xvnmaddmsp*, the single-precision floating-point value in word element i of VSR[XB] (where $i \in \{0, 1, 2, 3\}$).

src3 For *xvnmaddasp*, the single-precision floating-point value in word element i of VSR[XB] (where $i \in \{0, 1, 2, 3\}$). For *xvnmaddmsp*, the single-precision floating-point value in word element i of VSR[XT] (where $i \in \{0, 1, 2, 3\}$).

dQNaN Default quiet NaN (0x7FC0_0000).

NZF Nonzero finite number.

Rezd Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.

Q(x) Return a QNaN with the payload of x.

A(x,y) Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.
Note: If $x = -y$, v is considered to be an exact-zero-difference result (Rezd).

M(x,y) Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.

p The intermediate product having unbounded range and precision.

v The intermediate result having unbounded range and precision.

Let XT be the value TX concatenated with T.
 Let XA be the value AX concatenated with A.
 Let XB be the value BX concatenated with B.

For each vector element *i* from 0 to 1, do the following.
 Let *src1* be the double-precision floating-point operand in doubleword element *i* of VSR[XA].

For *xvmsubadp*, do the following.

- Let *src2* be the double-precision floating-point operand in doubleword element *i* of VSR[XT].
- Let *src3* be the double-precision floating-point operand in doubleword element *i* of VSR[XB].

For *xvmsubmdp*, do the following.

- Let *src2* be the double-precision floating-point operand in doubleword element *i* of VSR[XB].
- Let *src3* be the double-precision floating-point operand in doubleword element *i* of VSR[XT].

src1 is multiplied¹ by *src3*, producing a product having unbounded range and precision.

See part 1 of Table 93.

src2 is negated and added² to the product, producing a sum having unbounded range and precision.

The sum is normalized³.

See part 2 of Table 93.

The intermediate result is rounded to double-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 46, "Floating-Point Intermediate Result Handling," on page 344.

The result is negated and placed into doubleword element *i* of VSR[XT] in double-precision format.

See Table 91, "Vector Floating-Point Final Result with Negation," on page 466.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

Explanation:

src1	The double-precision floating-point value in doubleword element i of $\text{VSR}[\text{XA}]$ (where $i \in \{0, 1\}$).
src2	For <i>xvnmsubadp</i> , the double-precision floating-point value in doubleword element i of $\text{VSR}[\text{XT}]$ (where $i \in \{0, 1\}$). For <i>xvnmsubmdp</i> , the double-precision floating-point value in doubleword element i of $\text{VSR}[\text{XB}]$ (where $i \in \{0, 1\}$).
src3	For <i>xvnmsubadp</i> , the double-precision floating-point value in doubleword element i of $\text{VSR}[\text{XB}]$ (where $i \in \{0, 1\}$). For <i>xvnmsubmdp</i> , the double-precision floating-point value in doubleword element i of $\text{VSR}[\text{XT}]$ (where $i \in \{0, 1\}$).
dQNaN	Default quiet NaN ($0 \times 7 \text{FF}8_0000_0000_0000$).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
Q(x)	Return a QNaN with the payload of x .
S(x,y)	Return the normalized sum of floating-point value x and negated floating-point value y , having unbounded range and precision. Note: If $x = -y$, v is considered to be an exact-zero-difference result (Rezd).
M(x,y)	Return the normalized product of floating-point value x and floating-point value y , having unbounded range and precision.
p	The intermediate product having unbounded range and precision.
v	The intermediate result having unbounded range and precision.

```

Let XT be the value TX concatenated with T.
 Let XA be the value AX concatenated with A.
 Let XB be the value BX concatenated with B.

For each vector element *i* from 0 to 3, do the following.
 Let *src1* be the single-precision floating-point operand in word element *i* of VSR[XA].

- For *xvnmsubasp*, do the following.
- Let *src2* be the single-precision floating-point operand in word element *i* of VSR[XT].
 - Let *src3* be the single-precision floating-point operand in word element *i* of VSR[XB].

For *xvnmsubmsp*, do the following.

- Let *src2* be the single-precision floating-point operand in word element *i* of VSR[XB].
- Let *src3* be the single-precision floating-point operand in word element *i* of VSR[XT].

src1 is multiplied¹ by *src3*, producing a product having unbounded range and precision.

See part 1 of Table 94.

src2 is negated and added² to the product, producing a sum having unbounded range and precision.

The sum is normalized³.

See part 2 of Table 94.

The intermediate result is rounded to single-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 46, “Floating-Point Intermediate Result Handling,” on page 344.

The result is negated and placed into word element *i* of VSR[XT] in single-precision format.

See Table 91, “Vector Floating-Point Final Result with Negation,” on page 466.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

Special Registers Altered:

FX OX UX XX VXSNAN VXISI VXIMZ

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Let XT be the value TX concatenated with T.
 Let XA be the value AX concatenated with A.
 Let XB be the value BX concatenated with B.

For each vector element *i* from 0 to 3, do the following.
 Let *src1* be the single-precision floating-point operand in word element *i* of VSR[XA].

Let *src2* be the single-precision floating-point operand in word element *i* of VSR[XB].

src2 is negated and added¹ to *src1*, producing a sum having unbounded range and precision.

The sum is normalized².

See Table 98.

The intermediate result is rounded to single-precision using the rounding mode specified by the Floating-Point Rounding Control field RN of the FPSCR.

See Table 46, “Floating-Point Intermediate Result Handling,” on page 344.

The result is placed into word element *i* of VSR[XT] in single-precision format.

See Table 68, “Vector Floating-Point Final Result,” on page 400.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Explanation:

src1	The single-precision floating-point value in word element i of VSR[XA] (where $i \in \{0,1,2,3\}$).
src2	The single-precision floating-point value in word element i of VSR[XB] (where $i \in \{0,1,2,3\}$).
dQNaN	Default quiet NaN (0x7FC0_0000).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs).
S(x,y)	Return the normalized sum of floating-point value x and negated floating-point value y , having unbounded range and precision. Note: If $x = -y$, v is considered to be an exact-zero-difference result (Rezd).
Q(x)	Return a QNaN with the payload of x .
v	The intermediate result having unbounded significand precision and unbounded exponent range.

8.3.5.1 Integer Format	507		

8.1 Overview

The Signal Processing Engine (SPE) accelerates signal processing applications normally suited to DSP operation. This is accomplished using short vectors (two element) within 64-bit GPRs and using single instruction multiple data (SIMD) operations to perform the requisite computations. SPE also architects an Accumulator register to allow for back to back operations without loop unrolling.

8.2 Nomenclature and Conventions

Several conventions regarding nomenclature are used for SPE:

- The Signal Processing Engine category is abbreviated as SPE.
- Bits 0 to 31 of a 64-bit register are referenced as upper word, even word or high word element of the register. Bits 32:63 are referred to as lower word, odd word or low word element of the register. Each half is an element of a 64-bit GPR.
- Bits 0 to 15 and bits 32 to 47 are referenced as even halfwords. Bits 16 to 31 and bits 48 to 63 are referenced as odd halfwords.
- Mnemonics for SPE instructions generally begin with the letters 'ev' (embedded vector).

The RTL conventions in described below are used in addition to those described in Section 1.3:Additional RTL functions are described in Appendix D.

Notation Meaning

\times_{sf}	Signed fractional multiplication. Result of multiplying 2 signed fractional quantities having bit length n taking the least significant 2n-1 bits of the sign extended product and concatenating a 0 to the least significant bit forming a signed fractional result of 2n bits. Two 16-bit signed fractional quantities, a and b are multiplied, as shown below: $ea_{0:31} = \text{EXTS}(a)$ $eb_{0:31} = \text{EXTS}(b)$ $\text{prod}_{0:63} = ea \times eb$ $e\text{prod}_{0:63} = \text{EXTS}(\text{prod}_{32:63})$ $\text{result}_{0:31} = e\text{prod}_{33:63} \parallel 0b0$
\times_{gsf}	Guarded signed fractional multiplication. Result of multiplying 2 signed fractional quantities having bit length 16 taking the least significant 31 bits of the sign extended product and concatenating a 0 to the least significant bit forming a guarded signed fractional result of 64 bits. Since guarded signed fractional multiplication produces a 64-bit result, fractional input quantities of -1 and -1 can produce +1 in the intermediate product. Two 16-bit fractional quantities, a and b are multiplied, as shown below:

$ea_{0:31} = \text{EXTS}(a)$
 $eb_{0:31} = \text{EXTS}(b)$
 $prod_{0:63} = ea \times eb$
 $eprod_{0:63} = \text{EXTS}(prod_{32:63})$
 $result_{0:63} = eprod_{1:63} \parallel 0b0$

<< Logical shift left. $x \ll y$ shifts value x left by y bits, leaving zeros in the vacated bits.

>> Logical shift right. $x \gg y$ shifts value x right by y bits, leaving zeros in the vacated bits.

8.3 Programming Model

8.3.1 General Operation

SPE instructions generally take elements from one source register and operate on them with the corresponding elements of a second source register (and/or the accumulator) to produce results. Results are placed in the destination register and/or the accumulator. Instructions that are vector in nature (i.e. produce results of more than one element) provide results for each element that are independent of the computation of the other elements. These instructions can also be used to perform scalar DSP operations by ignoring the results of the upper 32-bit half of the register file.

There are no record forms of *SPE* instructions. As a result, the meaning of bits in the CR is different than for other categories. *SPE Compare* instructions specify a CR field, two source registers, and the type of compare: greater than, less than, or equal. Two bits of the CR field are written with the result of the vector compare, one for each element. The remaining two bits reflect the ANDing and ORing of the vector compare results.

8.3.2 GPR Registers

The SPE requires a GPR register file with thirty-two 64-bit registers. For 32-bit implementations, instructions that normally operate on a 32-bit register file access and change only the least significant 32-bits of the GPRs leaving the most significant 32-bits unchanged. For 64-bit implementations, operation of these instructions is unchanged, i.e. those instructions continue to operate on the 64-bit registers as they would if the SPE was not implemented. Most *SPE* instructions view the 64-bit register as being composed of a vector of two elements, each of which is 32 bits wide (some instructions read or write 16-bit elements). The most significant 32-bits are called the upper word, high word or even word. The least significant 32-bits are called the lower word, low word or odd word.

Unless otherwise specified, *SPE* instructions write all 64-bits of the destination register.

Figure 124. GPR

8.3.3 Accumulator Register

A partially visible accumulator register (ACC) is provided for some *SPE* instructions. The accumulator is a 64-bit register that holds the results of the *Multiply Accumulate (MAC)* forms of *SPE Fixed-Point* instructions. The accumulator allows the back-to-back execution of dependent *MAC* instructions, something that is found in the inner loops of DSP code such as FIR and FFT filters. The accumulator is partially visible to the programmer in the sense that its results do not have to be explicitly read to use them. Instead they are always copied into a 64-bit destination GPR which is specified as part of the instruction. Based upon the type of instruction, the accumulator can hold either a single 64-bit value or a vector of two 32-bit elements.

Figure 125. Accumulator

8.3.4 Signal Processing Embedded Floating-Point Status and Control Register (SPEFSCR)

Status and control for SPE uses the SPEFSCR register. This register is also used by the *SPE.Embedded Float Scalar Double*, *SPE.Embedded Float Scalar Single*, and *SPE.Embedded Float Vector* categories. Status and control bits are shared with these categories. The SPEFSCR register is implemented as special purpose register (SPR) number 512 and is read and written by the *mf spr* and *mt spr* instructions. *SPE* instructions affect both the high element (bits 32:33) and low element status flags (bits 48:49) of the SPEFSCR.

Figure 126. Signal Processing and Embedded Floating-Point Status and Control Register

The SPEFSCR bits are defined as shown below.

Bit	Description
32	Summary Integer Overflow High (SOVH) SOVH is set to 1 when an <i>SPE</i> instruction sets OVH. This is a sticky bit.

- 33 **Integer Overflow High (OVH)**
OVH is set to 1 to indicate that an overflow has occurred in the upper element during execution of an *SPE* instruction. The bit is set to 1 if a result of an operation performed by the instruction cannot be represented in the number of bits into which the result is to be placed, and is set to 0 otherwise. The OVH bit is not altered by *Modulo* instructions, nor by other instructions that cannot overflow.
- 34 **Embedded Floating-Point Guard Bit High (FGH)** [Category: SP.FV]
FGH is supplied for use by the Embedded Floating-Point Round interrupt handler. FGH is an extension of the low-order bits of the fractional result produced from an *SPE.Embedded Float Vector* instruction on the high word. FGH is zeroed if an overflow, underflow, or invalid input error is detected on the high element of an *SPE.Embedded Float Vector* instruction.
Execution of an *SPE.Embedded Float Scalar* instruction leaves FGH undefined.
- 35 **Embedded Floating-Point Inexact Bit High (FXH)** [Category: SP.FV]
FXH is supplied for use by the Embedded Floating-Point Round interrupt handler. FXH is an extension of the low-order bits of the fractional result produced from an *SPE.Embedded Float Vector* instruction on the high word. FXH represents the logical 'or' of all the bits shifted right from the Guard bit when the fractional result is normalized. FXH is zeroed if an overflow, underflow, or invalid input error is detected on the high element of an *SPE.Embedded Float Vector* instruction.
Execution of an *SPE.Embedded Float Scalar* instruction leaves FXH undefined.
- 36 **Embedded Floating-Point Invalid Operation/Input Error High (FINVH)** [Category: SP.FV]
The FINVH bit is set to 1 if any high word operand of an *SPE.Embedded Float Vector* instruction is infinity, NaN, or a denormalized value, or if the instruction is a divide and the dividend and divisor are both 0, or if a conversion to integer or fractional value overflows.
Execution of an *SPE.Embedded Float Scalar* instruction leaves FINVH undefined.
- 37 **Embedded Floating-Point Divide By Zero High (FDBZH)** [Category: SP.FV]
The FDBZH bit is set to 1 when an *SPE.Embedded Vector Floating-Point Divide* instruction is executed with a divisor of 0 in the high word operand, and the dividend is a finite nonzero number.
- 38 **Embedded Floating-Point Underflow High (FUNFH)** [Category: SP.FV]
The FUNFH bit is set to 1 when the execution of an *SPE.Embedded Float Vector* instruction results in an underflow on the high word operation.
Execution of an *SPE.Embedded Float Scalar* instruction leaves FUNFH undefined.
- 39 **Embedded Floating-Point Overflow High (FOVFH)** [Category: SP.FV]
The FOVFH bit is set to 1 when the execution of an *SPE.Embedded Float Vector* instruction results in an overflow on the high word operation.
Execution of an *SPE.Embedded Float Scalar* instruction leaves FOVFH undefined.
- 40:41 Reserved
- 42 **Embedded Floating-Point Inexact Sticky Flag (FINXS)** [Categories: SP.FV, SP.FD, SP.FS]
The FINXS bit is set to 1 whenever the execution of an *Embedded Floating-Point* instruction delivers an inexact result for either the low or high element and no Embedded Floating-Point Data interrupt is taken for either element, or if an *Embedded Floating-Point* instruction results in overflow (FOVF=1 or FOVFH=1), but Embedded Floating-Point Overflow exceptions are disabled (FOVFE=0), or if an *Embedded Floating-Point* instruction results in underflow (FUNF=1 or FUNFH=1), but Embedded Floating-Point Underflow exceptions are disabled (FUNFE=0), and no Embedded Floating-Point Data interrupt occurs. This is a sticky bit.
- 43 **Embedded Floating-Point Invalid Operation/Input Sticky Flag (FINVS)** [Categories: SP.FV, SP.FD, SP.FS]
The FINVS bit is defined to be the sticky result of any *Embedded Floating-Point* instruction that causes FINVH or FINV to be set to 1. That is, $FINVS \leftarrow FINVS \mid FINV \mid FINVH$. This is a sticky bit.
- 44 **Embedded Floating-Point Divide By Zero Sticky Flag (FDBZS)** [Categories: SP.FV, SP.FD, SP.FS]
The FDBZS bit is set to 1 when an *Embedded Floating-Point Divide* instruction sets FDBZH or FDBZ to 1. That is, $FDBZS \leftarrow FDBZS \mid FDBZ \mid FDBZH$. This is a sticky bit.
- 45 **Embedded Floating-Point Underflow Sticky Flag (FUNFS)** [Categories: SP.FV, SP.FD, SP.FS]
The FUNFS bit is defined to be the sticky

- result of any *Embedded Floating-Point* instruction that causes FUNFH or FUNF to be set to 1. That is, $FUNFS \leftarrow FUNFS \mid FUNF \mid FUNFH$. This is a sticky bit.
- 46 **Embedded Floating-Point Overflow Sticky Flag (FOVFS)** [Categories: SP.FV, SP.FD, SP.FS]
The FOVFS bit is defined to be the sticky result of any *Embedded Floating-Point* instruction that causes FOVH or FOVF to be set to 1. That is, $FOVFS \leftarrow FOVFS \mid FOVF \mid FOVH$. This is a sticky bit.
- 47 Reserved
- 48 **Summary Integer Overflow (SOV)**
SOV is set to 1 when an *SPE* instruction sets OV to 1. This is a sticky bit.
- 49 **Integer Overflow (OV)**
OV is set to 1 to indicate that an overflow has occurred in the lower element during execution of an *SPE* instruction. The bit is set to 1 if a result of an operation performed by the instruction cannot be represented in the number of bits into which the result is to be placed, and is set to 0 otherwise. The OV bit is not altered by *Modulo* instructions, nor by other instructions that cannot overflow.
- 50 **Embedded Floating-Point Guard Bit (Low/scalar) (FG)** [Categories: SP.FV, SP.FD, SP.FS]
FG is supplied for use by the Embedded Floating-Point Round interrupt handler. FG is an extension of the low-order bits of the fractional result produced from an *Embedded Floating-Point* instruction on the low word. FG is zeroed if an overflow, underflow, or invalid input error is detected on the low element of an *Embedded Floating-Point* instruction.
- 51 **Embedded Floating-Point Inexact Bit (Low/scalar) (FX)** [Categories: SP.FV, SP.FD, SP.FS]
FX is supplied for use by the Embedded Floating-Point Round interrupt handler. FX is an extension of the low-order bits of the fractional result produced from an *Embedded Floating-Point* instruction on the low word. FX represents the logical 'or' of all the bits shifted right from the Guard bit when the fractional result is normalized. FX is zeroed if an overflow, underflow, or invalid input error is detected on *Embedded Floating-Point* instruction
- 52 **Embedded Floating-Point Invalid Operation/Input Error (Low/scalar) (FINV)** [Categories: SP.FV, SP.FD, SP.FS]
The FINV bit is set to 1 if any low word operand of an *Embedded Floating-Point* instruction is infinity, NaN, or a denormalized value,
- or if the operation is a divide and the dividend and divisor are both 0, or if a conversion to integer or fractional value overflows.
- 53 **Embedded Floating-Point Divide By Zero (Low/scalar) (FDBZ)** [Categories: SP.FV, SP.FD, SP.FS]
The FDBZ bit is set to 1 when an *Embedded Floating-Point Divide* instruction is executed with a divisor of 0 in the low word operand, and the dividend is a finite nonzero number.
- 54 **Embedded Floating-Point Underflow (Low/scalar) (FUNF)** [Categories: SP.FV, SP.FD, SP.FS]
The FUNF bit is set to 1 when the execution of an *Embedded Floating-Point* instruction results in an underflow on the low word operation.
- 55 **Embedded Floating-Point Overflow (Low/scalar) (FOVF)** [Categories: SP.FV, SP.FD, SP.FS]
The FOVF bit is set to 1 when the execution of an *Embedded Floating-Point* instruction results in an overflow on the low word operation.
- 56 Reserved
- 57 **Embedded Floating-Point Round (Inexact) Exception Enable (FINXE)** [Categories: SP.FV, SP.FD, SP.FS]
0 Exception disabled
1 Exception enabled
The Embedded Floating-Point Round interrupt is taken if the exception is enabled and if $FG \mid FGH \mid FX \mid FXH$ (signifying an inexact result) is set to 1 as a result of an *Embedded Floating-Point* instruction.
If an *Embedded Floating-Point* instruction results in overflow or underflow and the corresponding Embedded Floating-Point Underflow or Embedded Floating-Point Overflow exception is disabled then the Embedded Floating-Point Round interrupt is taken.
- 58 **Embedded Floating-Point Invalid Operation/Input Error Exception Enable (FINVE)** [Categories: SP.FV, SP.FD, SP.FS]
0 Exception disabled
1 Exception enabled
If the exception is enabled, an Embedded Floating-Point Data interrupt is taken if the FINV or FINVH bit is set to 1 by an *Embedded Floating-Point* instruction.
- 59 **Embedded Floating-Point Divide By Zero Exception Enable (FDBZE)** [Categories: SP.FV, SP.FD, SP.FS]
0 Exception disabled

1 Exception enabled

If the exception is enabled, an Embedded Floating-Point Data interrupt is taken if the FDBZ or FDBZH bit is set to 1 by an *Embedded Floating-Point* instruction.

60 **Embedded Floating-Point Underflow Exception Enable** (FUNFE) [Categories: SP.FV, SP.FD, SP.FS]

0 Exception disabled
1 Exception enabled

If the exception is enabled, an Embedded Floating-Point Data interrupt is taken if the FUNF or FUNFH bit is set to 1 by an *Embedded Floating-Point* instruction.

61 **Embedded Floating-Point Overflow Exception Enable** (FOVFE) [Categories: SP.FV, SP.FD, SP.FS]

0 Exception disabled
1 Exception enabled

If the exception is enabled, an Embedded Floating-Point Data interrupt is taken if the FOVF or FOVFH bit is set to 1 by an *Embedded Floating-Point* instruction.

62:63 **Embedded Floating-Point Rounding Mode Control** (FRMC) [Categories: SP.FV, SP.FD, SP.FS]

00 Round to Nearest
01 Round toward Zero
10 Round toward +Infinity
11 Round toward -Infinity

Programming Note

Rounding modes 0b10 (+Infinity) and 0b11 (-Infinity) may not be supported by some implementations. If an implementation does not support these, Embedded Floating-Point Round interrupts are generated for every *Embedded Floating-Point* instruction for which rounding is required when +Infinity or -Infinity modes are set and software is required to produce the correctly rounded result

8.3.5 Data Formats

The SPE provides two different data formats, integer and fractional. Both data formats can be treated as signed or unsigned quantities.

8.3.5.1 Integer Format

Unsigned integers consist of 16, 32, or 64-bit binary integer values. The largest representable value is 2^{n-1} where n represents the number of bits in the value. The smallest representable value is 0. Computations that

produce values larger than 2^n-1 or smaller than 0 may set OV or OVH in the SPEFSCR.

Signed integers consist of 16, 32, or 64-bit binary values in two's complement form. The largest representable value is $2^{n-1}-1$ where n represents the number of bits in the value. The smallest representable value is -2^{n-1} . Computations that produce values larger than $2^{n-1}-1$ or smaller than -2^{n-1} may set OV or OVH in the SPEFSCR.

8.3.5.2 Fractional Format

Fractional data format is conventionally used for DSP fractional arithmetic. Fractional data is useful for representing data converted from analog devices.

Unsigned fractions consist of 16, 32, or 64-bit binary fractional values that range from 0 to less than 1. Unsigned fractions place the radix point immediately to the left of the most significant bit. The most significant bit of the value represents the value 2^{-1} , the next most significant bit represents the value 2^{-2} and so on. The largest representable value is $1-2^{-n}$ where n represents the number of bits in the value. The smallest representable value is 0. Computations that produce values larger than $1-2^{-n}$ or smaller than 0 may set OV or OVH in the SPEFSCR. The SPE category does not define unsigned fractional forms of instructions to manipulate unsigned fractional data since the unsigned integer forms of the instructions produce the same results as would the unsigned fractional forms.

Guarded unsigned fractions are 64-bit binary fractional values. Guarded unsigned fractions place the decimal point immediately to the left of bit 32. The largest representable value is $2^{32}-2^{-32}$. The smallest representable value is 0. Guarded unsigned fractional computations are always modulo and do not set OV or OVH in the SPEFSCR.

Signed fractions consist of 16, 32, or 64-bit binary fractional values in two's-complement form that range from -1 to less than 1. Signed fractions place the decimal point immediately to the right of the most significant bit. The largest representable value is $1-2^{-(n-1)}$ where n represents the number of bits in the value. The smallest representable value is -1. Computations that produce values larger than $1-2^{-(n-1)}$ or smaller than -1 may set OV or OVH in the SPEFSCR. Multiplication of two signed fractional values causes the result to be shifted left one bit to remove the resultant redundant sign bit in the product. In this case, a 0 bit is concatenated as the least significant bit of the shifted result.

Guarded signed fractions are 64-bit binary fractional values. Guarded signed fractions place the decimal point immediately to the left of bit 33. The largest representable value is $2^{32}-2^{-31}$. The smallest representable value is $-2^{32}-1+2^{-31}$. Guarded signed fractional computations are always modulo and do not set OV or OVH in the SPEFSCR.

8.3.6 Computational Operations

The SPE category supports several different computational capabilities. Both modulo and saturation results can be performed. Modulo results produce truncation of the overflow bits in a calculation, therefore overflow does not occur and no saturation is performed. For instructions for which overflow occurs, saturation provides a maximum or minimum representable value (for the data type) in the case of overflow. Instructions are provided for a wide range of computational capability. The operation types can be divided into 4 basic categories:

- *Simple Vector* instructions. These instructions use the corresponding low and high word elements of the operands to produce a vector result that is placed in the destination register, the accumulator, or both.
- *Multiply and Accumulate* instructions. These instructions perform multiply operations, optionally add the result to the accumulator, and place the result into the destination register and optionally into the accumulator. These instructions are composed of different multiply forms, data formats and data accumulate options. The mnemonics for these instructions indicate their various characteristics. These are shown in Table 99.
- *Load* and *Store* instructions. These instructions provide load and store capabilities for moving data to and from memory. A variety of forms are provided that position data for efficient computation.
- *Compare* and miscellaneous instructions. These instructions perform miscellaneous functions such as field manipulation, bit reversed incrementing, and vector compares.

Table 99: Mnemonic Extensions for Multiply Accumulate Instructions		
Extension	Meaning	Comments
Multiply Form		
<i>he</i>	halfword even	16 X 16 → 32
<i>heg</i>	halfword even guarded	16 X 16 → 32, 64-bit final accumulate result
<i>ho</i>	halfword odd	16 X 16 → 32
<i>hog</i>	halfword odd guarded	16 X 16 → 32, 64-bit final accumulate result
<i>w</i>	word	32 X 32 → 64
<i>wh</i>	word high	32 X 32 → 32 (high-order 32 bits of product)
<i>wl</i>	word low	32 X 32 → 32 (low-order 32 bits of product)
Data Format		
<i>smf</i>	signed modulo fractional	modulo, no saturation or overflow
<i>smi</i>	signed modulo integer	modulo, no saturation or overflow
<i>ssf</i>	signed saturate fractional	saturation on product and accumulate
<i>ssi</i>	signed saturate integer	saturation on product and accumulate
<i>umi</i>	unsigned modulo integer	modulo, no saturation or overflow
<i>usi</i>	unsigned saturate integer	saturation on product and accumulate
Accumulate Option		
<i>a</i>	place in accumulator	result → accumulator
<i>aa</i>	add to accumulator	accumulator + result → accumulator
<i>aaw</i>	add to accumulator as word elements	accumulator _{0:31} + result _{0:31} → accumulator _{0:31} accumulator _{32:63} + result _{32:63} → accumulator _{32:63}
<i>an</i>	add negated to accumulator	accumulator - result → accumulator
<i>anw</i>	add negated to accumulator as word elements	accumulator _{0:31} - result _{0:31} → accumulator _{0:31} accumulator _{32:63} - result _{32:63} → accumulator _{32:63}

8.3.7 SPE Instructions

8.3.8 Saturation, Shift, and Bit Reverse Models

For saturation, left shifts, and bit reversal, the pseudo RTL is provided here to more accurately describe those functions that are referenced in the instruction pseudo RTL.

8.3.8.1 Saturation

```
SATURATE(ov, carry, sat_ovn, sat_ov, val)
if ov then
    if carry then
        return sat_ovn
    else
        return sat_ov
else
    return val
```

8.3.8.2 Shift Left

```
SL(value, cnt)
if cnt > 31 then
    return 0
else
    return (value << cnt)
```

8.3.8.3 Bit Reverse

```
BITREVERSE(value)
result ← 0
mask ← 1
shift ← 31
cnt ← 32
while cnt > 0 then do
    t ← value & mask
    if shift >= 0 then
        result ← (t << shift) | result
    else
        result ← (t >> -shift) | result
    cnt ← cnt - 1
    shift ← shift - 2
    mask ← mask << 1
return result
```

8.3.9 SPE Instruction Set

Bit Reversed Increment

EVX-form

brinc RT,RA,RB

$n \leftarrow$ implementation-dependent number of mask bits
 $\text{mask} \leftarrow (\text{RB})_{64-n:63}$
 $a \leftarrow (\text{RA})_{64-n:63}$
 $d \leftarrow \text{BITREVERSE}(1 + \text{BITREVERSE}(a \mid (\neg \text{mask})))$
 $\text{RT} \leftarrow (\text{RA})_{0:63-n} \mid (d \ \& \ \text{mask})$

brinc computes a bit-reverse index based on the contents of RA and a mask specified in RB. The new index is written to RT.

The number of bits in the mask is implementation-dependent but may not exceed 32.

Special Registers Altered:

None

Programming Note

brinc provides a way for software to access FFT data in a bit-reversed manner. RA contains the index into a buffer that contains data on which FFT is to be performed. RB contains a mask that allows the index to be updated with bit-reversed addressing. Typically this instruction precedes a load with index instruction; for example,

```
brinc r2, r3, r4
lhax r8, r5, r2
```

RB contains a bit-mask that is based on the number of points in an FFT. To access a buffer containing n byte sized data that is to be accessed with bit-reversed addressing, the mask has $\log_2 n$ 1s in the least significant bit positions and 0s in the remaining most significant bit positions. If, however, the data size is a multiple of a halfword or a word, the mask is constructed so that the 1s are shifted left by \log_2 (size of the data) and 0s are placed in the least significant bit positions.

Programming Note

This instruction only modifies the lower 32 bits of the destination register in 32-bit implementations. For 64-bit implementations in 32-bit mode, the contents of the upper 32-bits of the destination register are undefined.

Programming Note

Execution of **brinc** does not cause SPE Unavailable exceptions regardless of MSR_{SPV} .

Vector Absolute Value

EVX-form

evabs RT,RA

$\text{RT}_{0:31} \leftarrow \text{ABS}((\text{RA})_{0:31})$
 $\text{RT}_{32:63} \leftarrow \text{ABS}((\text{RA})_{32:63})$

The absolute value of each element of RA is placed in the corresponding elements of RT. An absolute value of 0x8000_0000 (most negative number) returns 0x8000_0000.

Special Registers Altered:

None

Vector Add Immediate Word

EVX-form

evaddiw RT,RB,UI

$\text{RT}_{0:31} \leftarrow (\text{RB})_{0:31} + \text{EXTZ}(\text{UI})$
 $\text{RT}_{32:63} \leftarrow (\text{RB})_{32:63} + \text{EXTZ}(\text{UI})$

UI is zero-extended and added to both the high and low elements of RB and the results are placed in RT. Note that the same value is added to both elements of the register.

Special Registers Altered:

None

Vector Add Signed, Modulo, Integer to Accumulator Word

EVX-form

evaddsmiaaw RT,RA

$\text{RT}_{0:31} \leftarrow (\text{ACC})_{0:31} + (\text{RA})_{0:31}$
 $\text{RT}_{32:63} \leftarrow (\text{ACC})_{32:63} + (\text{RA})_{32:63}$
 $\text{ACC}_{0:63} \leftarrow (\text{RT})_{0:63}$

Each word element in RA is added to the corresponding element in the accumulator and the results are placed in RT and into the accumulator.

Special Registers Altered:

```

The corresponding even-numbered halfword signed fractional elements in RA and RB are multiplied producing a 32-bit product. If both inputs are -1.0, the result saturates to 0x7FFF_FFFF. Each 32-bit product is then subtracted from the corresponding word in the accumulator saturating if overflow occurs, and the result is placed in RT and the accumulator.

0	6	11	16	21
				31

```
RT0:31 ← ((RA)0:31+0x00008000) & 0xFFFF0000
RT32:63 ← ((RA)32:63+0x00008000) & 0xFFFF0000
```

The 32-bit elements of RA are rounded into 16 bits. The result is placed in RT. The resulting 16 bits are placed in the most significant 16 bits of each element of RT, zeroing out the low-order 16 bits of each element.

Special Registers Altered:

None

Vector Shift Left Word**EVX-form**

evslw RT,RA,RB

$$\begin{aligned} nh &\leftarrow (RB)_{26:31} \\ nl &\leftarrow (RB)_{58:63} \\ RT_{0:31} &\leftarrow SL((RA)_{0:31}, nh) \\ RT_{32:63} &\leftarrow SL((RA)_{32:63}, nl) \end{aligned}$$

Each of the high and low elements of RA is shifted left by an amount specified in RB. The result is placed in RT. The separate shift amounts for each element are specified by 6 bits in RB that lie in bit positions 26:31 and 58:63.

Shift amounts from 32 to 63 give a zero result.

Special Registers Altered:

None

Vector Splat Fractional Immediate**EVX-form**

evsplatfi RT,SI

$$\begin{aligned} RT_{0:31} &\leftarrow SI \parallel 27_0 \\ RT_{32:63} &\leftarrow SI \parallel 27_0 \end{aligned}$$

The value specified by SI is padded with trailing zeros and placed in both elements of RT. The SI ends up in bit positions $RT_{0:4}$ and $RT_{32:36}$.

Special Registers Altered:

None

Vector Shift Right Word Immediate Signed**EVX-form**

evsrwis RT,RA,UI

$$\begin{aligned} n &\leftarrow UI \\ RT_{0:31} &\leftarrow EXTZ((RA)_{0:31-n}) \\ RT_{32:63} &\leftarrow EXTZ((RA)_{32:63-n}) \end{aligned}$$

Both high and low elements of RA are shifted right by the 5-bit UI value. Bits in the most significant positions vacated by the shift are filled with a copy of the sign bit.

Special Registers Altered:

None

Vector Shift Left Word Immediate EVX-form

evslwi RT,RA,UI

$$\begin{aligned} n &\leftarrow UI \\ RT_{0:31} &\leftarrow SL((RA)_{0:31}, n) \\ RT_{32:63} &\leftarrow SL((RA)_{32:63}, n) \end{aligned}$$

Both high and low elements of RA are shifted left by the 5-bit UI value and the results are placed in RT.

Special Registers Altered:

None

Vector Splat Immediate**EVX-form**

evsplati RT,SI

$$\begin{aligned} RT_{0:31} &\leftarrow EXTZ(SI) \\ RT_{32:63} &\leftarrow EXTZ(SI) \end{aligned}$$

The value specified by SI is sign extended and placed in both elements of RT.

Special Registers Altered:

None

Vector Shift Right Word Immediate Unsigned**EVX-form**

evsrwiu RT,RA,UI

$$\begin{aligned} n &\leftarrow UI \\ RT_{0:31} &\leftarrow EXTZ((RA)_{0:31-n}) \\ RT_{32:63} &\leftarrow EXTZ((RA)_{32:63-n}) \end{aligned}$$

Both high and low elements of RA are shifted right by the 5-bit UI value; zeros are shifted into the most significant position.

Special Registers Altered:

None

Vector Shift Right Word Signed EVX-form

evsrws RT,RA,RB

Vector Shift Right Word Unsigned EVX-form

evsrwu RT,RA,RB

4	RT	RA	RB	544
0	6	11	16	21
31				

$nh \leftarrow (RB)_{26:31}$
 $nl \leftarrow (RB)_{58:63}$
 $RT_{0:31} \leftarrow EXTZ((RA)_{0:31-nh})$
 $RT_{32:63} \leftarrow EXTZ((RA)_{32:63-nl})$

Both the high and low elements of RA are shifted right by an amount specified in RB. The result is placed in RT. The separate shift amounts for each element are specified by 6 bits in RB that lie in bit positions 26:31 and 58:63. Zeros are shifted into the most significant position.

Shift amounts from 32 to 63 give a zero result.

9.1 Overview

The *Embedded Floating-Point* categories require the implementation of the Signal Processing Engine (SPE) category and consist of three distinct categories:

- Embedded vector single-precision floating-point (SPE.Embedded Float Vector [SP.FV])
- Embedded scalar single-precision floating-point (SPE.Embedded Float Scalar Single [SP.FS])
- Embedded scalar double-precision floating-point (SPE.Embedded Float Scalar Double [SP.FD])

Although each of these may be implemented independently, they are defined in a single chapter because it is likely that they may be implemented together.

References to *Embedded Floating-Point* categories, *Embedded Floating-Point* instructions, or *Embedded Floating-Point* operations apply to all 3 categories.

Single-precision floating-point is handled by the SPE.Embedded Float Vector and SPE.Embedded Float Scalar Single categories; double-precision floating-point is handled by the SPE.Embedded Float Scalar Double category.

9.2 Programming Model

Embedded floating-point operations are performed in the GPRs of the processor.

The SPE.Embedded Float Vector and SPE.Embedded Float Scalar Double categories require a GPR register file with thirty-two 64-bit registers as required by the Signal Processing Engine category.

The SPE.Embedded Float Scalar Single category requires a GPR register file with thirty-two 32-bit registers. When implemented with a 64-bit register file on a 32-bit implementation, instructions in this category only use and modify bits 32:63 of the GPR. In this case, bits 0:31 of the GPR are left unchanged by the operation. For 64-bit implementations, bits 0:31 are unchanged after the operation.

Instructions in the SPE.Embedded Float Scalar Double category operate on the entire 64 bits of the GPRs.

Instructions in the SPE.Embedded Float Vector category operate on the entire 64 bits of the GPRs as well, but contain two 32-bit data items that are operated on independently of each other in a SIMD fashion. The format of both data items is the same as the format of a data item in the SPE.Embedded Float Scalar Single category. The data item contained in bits 0:31 is called the 'high word'. The data item contained in bits 32:63 is called the 'low word'.

There are no record forms of *Embedded Floating-Point* instructions. *Embedded Floating-Point Compare* instructions treat NaNs, Infinity, and Denorm as normalized numbers for the comparison calculation when default results are provided.

9.2.1 Signal Processing Embedded Floating-Point Status and Control Register (SPEFSCR)

Status and control for the *Embedded Floating-Point* categories uses the SPEFSCR. This register is defined by the Signal Processing Engine category in Section 8.3.4. Status and control bits are shared for *Embedded Floating-Point* and SPE operations. Instructions in the SPE.Embedded Float Vector category affect both the high element (bits 34:39) and low element floating-point status flags (bits 50:55). Instructions in the SPE.Embedded Float Scalar Double and SPE.Embedded Float Scalar Single categories affect only the low element floating-point status flags and leave the high element floating-point status flags undefined.

9.2.2 Floating-Point Data Formats

Single-precision floating-point data elements are 32 bits wide with 1 sign bit (*s*), 8 bits of biased exponent (*e*) and 23 bits of fraction (*f*). Double-precision float-

ing-point data elements are 64 bits wide with 1 sign bit (*s*), 11 bits of biased exponent (*e*) and 52 bits of fraction (*f*).

In the IEEE 754 specification, floating-point values are represented in a format consisting of three explicit fields (sign field, biased exponent field, and fraction field) and an implicit hidden bit.

Figure 127. Floating-Point Data Format

For single-precision normalized numbers, the biased exponent value *e* lies in the range of 1 to 254 corresponding to an actual exponent value *E* in the range -126 to +127. For double-precision normalized numbers, the biased exponent value *e* lies in the range of 1 to 2046 corresponding to an actual exponent value *E* in the range -1022 to +1023. With the hidden bit implied to be '1' (for normalized numbers), the value of the number is interpreted as follows:

$$(-1)^s \times 2^E \times (1.\text{fraction})$$

where *E* is the unbiased exponent and 1.fraction is the mantissa (or significand) consisting of a leading '1' (the hidden bit) and a fractional part (fraction field). For the single-precision format, the maximum positive normalized number (*pmax*) is represented by the encoding 0x7F7FFFFFFF which is approximately 3.4E+38 (2^{128}), and the minimum positive normalized value (*pmin*) is represented by the encoding 0x00800000 which is approximately 1.2E-38 (2^{-126}). For the double-precision format, the maximum positive normalized number (*pmax*) is represented by the encoding 0x7EFFFFFF_FFFFFFFF which is approximately 1.8E+307 (2^{1024}), and the minimum positive normalized value (*pmin*) is represented by the encoding 0x00100000_00000000 which is approximately 2.2E-308 (2^{-1022}).

Two specific values of the biased exponent are reserved (0 and 255 for single-precision; 0 and 2047 for double-precision) for encoding special values of +0, -0, +infinity, -infinity, and NaNs.

Zeros of both positive and negative sign are represented by a biased exponent value *e* of 0 and a fraction *f* which is 0.

Infinities of both positive and negative sign are represented by a maximum exponent field value (255 for single-precision, 2047 for double-precision) and a fraction which is 0.

Denormalized numbers of both positive and negative sign are represented by a biased exponent value e of 0 and a fraction f , which is nonzero. For these numbers, the hidden bit is defined by the IEEE 754 standard to be 0. This number type is not directly supported in hardware. Instead, either a software interrupt handler is invoked, or a default value is defined.

Not-a-Numbers (NaNs) are represented by a maximum exponent field value (255 for single-precision, 2047 for double-precision) and a fraction f which is nonzero.

9.2.3 Exception Conditions

9.2.3.1 Denormalized Values on Input

Any denormalized value used as an operand may be truncated by the implementation to a properly signed zero value.

9.2.3.2 Embedded Floating-Point Overflow and Underflow

Defining $pmax$ to be the most positive normalized value (farthest from zero), $pmin$ the smallest positive normalized value (closest to zero), $nmax$ the most negative normalized value (farthest from zero) and $nmin$ the smallest normalized negative value (closest to zero), an overflow is said to have occurred if the numerically correct result (r) of an instruction is such that $r > pmax$ or $r < nmax$. An underflow is said to have occurred if the numerically correct result of an instruction is such that $0 < r < pmin$ or $nmin < r < 0$. In this case, r may be denormalized, or may be smaller than the smallest denormalized number.

The *Embedded Floating-Point* categories do not produce +Infinity, -Infinity, NaN, or denormalized numbers. If the result of an instruction overflows and Embedded Floating-Point Overflow exceptions are disabled ($SPEFSCR_{FOVFE}=0$), $pmax$ or $nmax$ is generated as the result of that instruction depending upon the sign of the result. If the result of an instruction underflows and Embedded Floating-Point Underflow exceptions are disabled ($SPEFSCR_{FUNFE}=0$), +0 or -0 is generated as the result of that instruction based upon the sign of the result.

If an overflow occurs, $SPEFSCR_{FOVF}$ $FOVFH$ are set appropriately, or if an underflow occurs, $SPEFSCR_{FUNF}$ $FUNFH$ are set appropriately. If either Embedded Floating-Point Underflow or Embedded Floating-Point Overflow exceptions are enabled and a corresponding status bit is 1, an Embedded Floating-Point Data interrupt is taken and the destination register is not updated.

Programming Note

On some implementations, operations that result in overflow or underflow are likely to take significantly longer than operations that do not. For example, these operations may cause a system error handler to be invoked; on such implementations, the system error handler updates the overflow bits appropriately.

9.2.3.3 Embedded Floating-Point Invalid Operation/Input Errors

Embedded Floating-Point Invalid Operation/Input errors occur when an operand to an operation contains an invalid input value. If any of the input values are Infinity, Denorm, or NaN, or for an *Embedded Floating-Point Divide* instruction both operands are +/-0, $SPEFSCR_{FINV}$ $FINVH$ are set to 1 appropriately, and $SPEFSCR_{FGH}$ FXH FG FX are set to 0 appropriately. If $SPEFSCR_{FINVE}=1$, an Embedded Floating-Point Data interrupt is taken and the destination register is not updated.

9.2.3.4 Embedded Floating-Point Round (Inexact)

If any result element of an *Embedded Floating-Point* instruction is inexact, or overflows but Embedded Floating-Point Overflow exceptions are disabled, or underflows but Embedded Floating-Point Underflow exceptions are disabled, and no higher priority interrupt occurs, $SPEFSCR_{FINXS}$ is set to 1. If the Embedded Floating-Point Round (Inexact) exception is enabled, an Embedded Floating-Point Round interrupt occurs. In this case, the destination register is updated with the truncated result(s). The $SPEFSCR_{FGH}$ FXH FG FX bits are properly updated to allow rounding to be performed in the interrupt handler.

$SPEFSCR_{FG}$ FX ($SPEFSCR_{FGH}$ FXH) are set to 0 if an Embedded Floating-Point Data interrupt is taken due to overflow, underflow, or if an Embedded Floating-Point Invalid Operation/Input error is signaled for the low (high) element (regardless of $SPEFSCR_{FINVE}$).

9.2.3.5 Embedded Floating-Point Divide by Zero

If an *Embedded Floating-Point Divide* instruction executes and an Embedded Floating-Point Invalid Operation/Input error does not occur and the instruction is executed with a +/-0 divisor value and a finite normalized nonzero dividend value, an Embedded Floating-Point Divide By Zero exception occurs and $SPEFSCR_{FDBZ}$ $FDBZH$ are set appropriately. If Embedded Floating-Point Divide By Zero exceptions are enabled, an Embedded Floating-Point Data

interrupt is then taken and the destination register is not updated.

9.2.3.6 Default Results

Default results are generated when an Embedded Floating-Point Invalid Operation/Input Error, Embedded Floating-Point Overflow, Embedded Floating-Point Underflow, or Embedded Floating-Point Divide by Zero occurs on an *Embedded Floating-Point* operation. Default results provide a normalized value as a result of the operation. In general, Denorm results and underflows are set to 0 and overflows are saturated to the maximum representable number.

Default results produced for each operation are described in Section 9.4, “Embedded Floating-Point Results Summary”.

9.2.4 IEEE 754 Compliance

The *Embedded Floating-Point* categories require a floating-point system as defined in the ANSI/IEEE Standard 754-1985 but may rely on software support in order to conform fully with the standard. Thus, whenever an input operand of the *Embedded Floating-Point* instruction has data values that are +Infinity, -Infinity, Denormalized, NaN, or when the result of an operation produces an overflow or an underflow, an Embedded Floating-Point Data interrupt may be taken and the interrupt handler is responsible for delivering IEEE 754 compliant behavior if desired.

When Embedded Floating-Point Invalid Operation/Input Error exceptions are disabled ($SPEFSCR_{FINVE} = 0$), default results are provided by the hardware when an Infinity, Denormalized, or NaN input is received, or for the operation 0/0. When Embedded Floating-Point Underflow exceptions are disabled ($SPEFSCR_{FUNFE} = 0$) and the result of a floating-point operation underflows, a signed zero result is produced. The Embedded Floating-Point Round (Inexact) exception is also signaled for this condition. When Embedded Floating-Point Overflow exceptions are disabled ($SPEFSCR_{FOVFE} = 0$) and the result of a floating-point operation overflows, a *pmax* or *nmax* result is produced. The Embedded Floating-Point Round (Inexact) exception is also signaled for this condition. An exception enable flag ($SPEFSCR_{FINXE}$) is also provided for generating an Embedded Floating-Point Round interrupt when an inexact result is produced, to allow a software handler to conform to the IEEE 754 standard. An Embedded Floating-Point Divide By Zero exception enable flag ($SPEFSCR_{FDBZE}$) is provided for generating an Embedded Floating-Point Data interrupt when a divide by zero operation is attempted to allow a software handler to conform to the IEEE 754 standard. All of these exceptions may be disabled, and the hardware will then deliver an appropriate default result.

The sign of the result of an addition operation is the sign of the source operand having the larger absolute value. If both operands have the same sign, the sign of the result is the same as the sign of the operands. This includes subtraction which is addition with the negation of the sign of the second operand. The sign of the result of an addition operation with operands of differing signs for which the result is zero is positive except when rounding to negative infinity. Thus $-0 + -0 = -0$, and all other cases which result in a zero value give +0 unless the rounding mode is round to negative infinity.

Programming Note

Note that when exceptions are disabled and default results computed, operations having input values that are denormalized may provide different results on different implementations. An implementation may choose to use the denormalized value or a zero value for any computation. Thus a computational operation involving a denormalized value and a normal value may return different results depending on the implementation.

9.2.4.1 Sticky Bit Handling For Exception Conditions

The SPEFSCR register defines sticky bits for retaining information about exception conditions that are detected. There are 5 sticky bits (FINXS, FINVS, FDBZS, FUNFS and FOVFS) that can be used to help provide IEEE 754 compliance. The sticky bits represent the combined ‘or’ of all the previous status bits produced from any *Embedded Floating-Point* operation since the last time software zeroed the sticky bit. The hardware will never set a sticky bit to 0.

9.3 Embedded Floating-Point Instructions

9.3.1 Load/Store Instructions

Embedded Floating-Point instructions use GPRs to hold and operate on floating-point values. The *Embedded Floating-Point* categories do not define *Load* and *Store* instructions to move the data to and from memory, but instead rely on existing instructions in Book I to load and store data.

$$RT_{32:63} \leftarrow 0b0 \mid \mid (RA)_{33:63}$$

The sign bit of each element in register RA is set to 0 and the results are placed into register RT.

Regardless of the value of register RA, no exceptions are taken during the execution of this instruction.

Special Registers Altered:
None

9.3.2 SPE.Embedded Float Vector Instructions [Category: SPE.Embedded Float Vector]

All SPE.Embedded Float Vector instructions are single-precision. There are no vector floating-point double-precision instructions

Vector Floating-Point Single-Precision Negative Absolute Value *EVX-form*

evfsnabs RT,RA

4	RT	RA	///	645
0	6	11	16	31

$$RT_{0:31} \leftarrow 0b1 \mid \mid (RA)_{1:31}$$

$$RT_{32:63} \leftarrow 0b1 \mid \mid (RA)_{33:63}$$

The sign bit of each element in register RA is set to 1 and the results are placed into register RT.

Regardless of the value of register RA, no exceptions are taken during the execution of this instruction.

Special Registers Altered:
None

Vector Floating-Point Single-Precision Negate *EVX-form*

evfsneg RT,RA

4	RT	RA	///	646
0	6	11	16	31

$$RT_{0:31} \leftarrow \neg(RA)_0 \mid \mid (RA)_{1:31}$$

$$RT_{32:63} \leftarrow \neg(RA)_{32} \mid \mid (RA)_{33:63}$$

The sign bit of each element in register RA is complemented and the results are placed into register RT.

Regardless of the value of register RA, no exceptions are taken during the execution of this instruction.

Special Registers Altered:
None

Vector Floating-Point Single-Precision Add
EVX-form

evfsadd RT,RA,RB

4	RT	RA	RB	640

Vector Floating-Point Single-Precision Compare Greater Than EVX-form

evfscmpgt BF,RA,RB

```

ah ← (RA)0:31
al ← (RA)32:63
bh ← (RB)0:31
bl ← (RB)32:63
if (ah > bh) then ch ← 1
else ch ← 0
if (al > bl) then cl ← 1
else cl ← 0
CR4×BF:4×BF+3 ← ch || cl || (ch | cl) || (ch & cl)

```

Each element of register RA is compared against the corresponding element of register RB. The results of the comparisons are placed into CR field BF. If RA_{0:31} is greater than RB_{0:31}, bit 0 of CR field BF is set to 1, otherwise it is set to 0. If RA_{32:63} is greater than RB_{32:63}, bit 1 of CR field BF is set to 1, otherwise it is set to 0. Bit 2 of CR field BF is set to the OR of both result bits and Bit 3 of CR field BF is set to the AND of both result bits. Comparison ignores the sign of 0 (+0 = -0).

If an input error occurs and default results are generated, NaNs, Infinities, and Denorms as treated as normalized numbers, using their values of 'e' and 'f' directly.

Floating-Point Single-Precision Test Greater Than EVX-form

efststgt BF,RA,RB

4	BF	//	RA	RB	732
0	6	9	11	16	21
					31

```

al ← (RA)32:63
bl ← (RB)32:63
if (al > bl) then c1 ← 1
else c1 ← 0
CR4×BF:4×BF+3 ← undefined || c1 || undefined || undefined

```

The low element of register RA is compared against the low element of register RB. If RA_{32:63} is greater than RB_{32:63}, bit 1 of CR field BF is set to 1, otherwise it is set to 0. Bits 0, 2, and 3 of CR field BF are undefined. Comparison ignores the sign of 0 (+0 = -0). The comparison proceeds after treating NaNs, Infinities, and Denorms as normalized numbers, using their values of 'e' and 'f' directly.

No exceptions are generated during the execution of *efststgt*.

Special Registers Altered:

CR field BF

Programming Note

In an implementation, the execution of *efststgt* is likely to be faster than the execution of *efscmpgt*; however, if strict IEEE 754 compliance is required, the program should use *efscmpgt*.

Floating-Point Single-Precision Test Less Than EVX-form

efstslt BF,RA,RB

```

al ← (RA)32:63
bl ← (RB)32:63
if (al < bl) then c1 ← 1
else c1 ← 0
CR4×BF:4×BF+3 ← undefined || c1 || undefined || undefined

```

The low element of register RA is compared against the low element of register RB. If $RA_{32:63}$ is less than $RB_{32:63}$, bit 1 of CR field BF is set to 1, otherwise it is set to 0. Bits 0, 2, and 3 of CR field BF are undefined. Comparison ignores the sign of 0 (+0 = -0). The comparison proceeds after treating NaNs, Infinities, and Denorms as normalized numbers, using their values of 'e' and 'f' directly.

No exceptions are generated during the execution of **efstslt**.

Special Registers Altered:

CR field BF

Programming Note

In an implementation, the execution of **efstslt** is likely to be faster than the execution of **efscmplt**; however, if strict IEEE 754 compliance is required, the program should use **efscmplt**.

Floating-Point Single-Precision Test Equal EVX-form

efstseq BF,RA,RB

```

al ← (RA)32:63
bl ← (RB)32:63
if (al = bl) then c1 ← 1
else c1 ← 0
CR4×BF:4×BF+3 ← undefined || c1 || undefined || undefined

```

The low element of register RA is compared against the low element of register RB. If $RA_{32:63}$ is equal to $RB_{32:63}$, bit 1 of CR field BF is set to 1, otherwise it is set to 0. Bits 0, 2, and 3 of CR field BF are undefined. Comparison ignores the sign of 0 (+0 = -0). The comparison proceeds after treating NaNs, Infinities, and Denorms as normalized numbers, using their values of 'e' and 'f' directly.

No exceptions are generated during the execution of **efstseq**.

Special Registers Altered:

CR field BF

Programming Note

In an implementation, the execution of **efstseq** is likely to be faster than the execution of **efscmpeq**; however, if strict IEEE 754 compliance is required, the program should use **efscmpeq**.

9.3.4 SPE.Embedded Float Scalar Double Instructions [Category: SPE.Embedded Float Scalar Double]

Floating-Point Double-Precision Absolute Value EVX-form

efdabs RT,RA

4	RT	RA	///	740
0	6	11	16	21
0				31

$$RT_{0:63} \leftarrow 0b0 \mid \mid (RA)_{1:63}$$

The sign bit of register RA is set to 0 and the result is placed in register RT.

Regardless of the value of register RA, no exceptions are taken during the execution of this instruction.

Special Registers Altered:

None

Floating-Point Double-Precision Negative Absolute Value EVX-form

efdnabs RT,RA

4	RT	RA	///	741
0	6	11	16	21
0				31

$$RT_{0:63} \leftarrow 0b1 \mid \mid (RA)_{1:63}$$

The sign bit of register RA is set to 1 and the result is placed in register RT.

Regardless of the value of register RA, no exceptions are taken during the execution of this instruction.

Special Registers Altered:

None

Floating-Point Double-Precision Negate EVX-form

efdneg RT,RA

4	RT	RA	///	742
0	6	11	16	21
0				31

$$RT_{0:63} \leftarrow \neg(RA)_0 \mid \mid (RA)_{1:63}$$

The sign bit of register RA is complemented and the result is placed in register RT.

Regardless of the value of register RA, no exceptions are taken during the execution of this instruction.

Special Registers Altered:

None

**Floating-Point Double-Precision Add
EVX-form**

efdadd RT,RA,RB

4	RT	RA	RB	736
0	6	11	16	31

$$RT_{0:63} \leftarrow (RA)_{0:63} +_{dp} (RB)_{0:63}$$

RA is added to RB and the result is stored in register RT.

If an underflow occurs, +0 (for rounding modes RN, RZ, RP) or -0 (for rounding mode RM) is stored in register RT.

Special Registers Altered:

FINV FINVS

9.4 Embedded Floating-Point Results Summary

The following tables summarize the results of various types of *Embedded Floating-Point* operations on various combinations of input operands. Flag settings are performed on appropriate element flags. For all the tables the following annotation and general rules apply:

- * denotes that this status flag is set based on the results of the calculation.
- *_Calc_* denotes that the result is updated with the results of the computation.
- *max* denotes the maximum normalized number with the sign set to the computation [sign(operand A) XOR sign(operand B)].
- *amax* denotes the maximum normalized number with the sign set to the sign of Operand A.
- *bmax* denotes the maximum normalized number with the sign set to the sign of Operand B.
- *pmax* denotes the maximum normalized positive number. The encoding for single-precision is: 0x7F7FFFFFFF. The encoding for double-precision is: 0x7FEFFFFFFF_FFFFFFFF.
- *nmax* denotes the maximum normalized negative number. The encoding for single-precision is: 0xFF7FFFFFFF. The encoding for double-precision is: 0xFFEFFFFFFF_FFFFFFFF.
- *pmin* denotes the minimum normalized positive number. The encoding for single-precision is: 0x00800000. The encoding for double-precision is: 0x00100000_00000000.

- *nmin* denotes the minimum normalized negative number. The encoding for single-precision is: 0x80800000. The encoding for double-precision is: 0x80100000_00000000.
- Calculations that overflow or underflow saturate. Overflow for operations that have a floating-point result force the result to *max*. Underflow for operations that have a floating-point result force the result to zero. Overflow for operations that have a signed integer result force the result to 0x7FFFFFFF (positive) or 0x80000000 (negative). Overflow for operations that have an unsigned integer result force the result to 0xFFFFFFFF (positive) or 0x00000000 (negative).
- ¹ (superscript) denotes that the sign of the result is positive when the sign of Operand A and the sign of Operand B are different, for all rounding modes except round to -infinity, where the sign of the result is then negative.
- ² (superscript) denotes that the sign of the result is positive when the sign of Operand A and the sign of Operand B are the same, for all rounding modes except round to -infinity, where the sign of the result is then negative.
- ³ (superscript) denotes that the sign for any multiply or divide is always the result of the operation [sign(Operand A) XOR sign(Operand B)].
- ⁴ (superscript) denotes that if an overflow is detected, the result may be saturated.

Chapter 10. Legacy Move Assist Instruction [Category: Legacy Move Assist]

Determine Leftmost Zero Byte	X-form	Special Registers Altered:	
dlnzb	RA,RS,RB	(Rc=0)	XER _{57:63}
dlnzb.	RA,RS,RB	(Rc=1)	CR0 (if Rc=1)

31	RS	RA	RB	78	Rc
0	6	11	16	21	31

```

d0:63 ← (RS)32:63 || (RB)32:63
i ← 0
x ← 0
y ← 0
do while (x<8) & (y=0)
  x ← x + 1
  if di+32:i+39 = 0 then
    y ← 1
  else
    i ← i + 8
RA ← x
XER57:63 ← x
if Rc = 1 then do
  CR35 ← SO
  if y = 1 then do
    if x<5 then CR32:34 ← 0b010
    else CR32:34 ← 0b100
  else
    CR32:34 ← 0b001

```

The contents of bits 32:63 of register RS and the contents of bits 32:63 of register RB are concatenated to form an 8-byte operand. The operand is searched for the leftmost byte in which each bit is 0 (i.e., a null byte).

Bytes in the operand are numbered from left to right starting with 1. If a null byte is found, its byte number is placed into bits 57:63 of the XER and into register RA. Otherwise, the value 0b000_1000 is placed into both bits 57:63 of the XER and register RA.

If Rc is equal to 1, SO is copied into bit 35 of the CR and bits 32:34 of the CR are updated as follows:

- If no null byte is found, bits 32:34 of the CR are set to 0b001.
- If the leftmost null byte is in the first 4 bytes (i.e., from register RS), bits 32:34 of the CR are set to 0b010.
- If the leftmost null byte is in the last 4 bytes (i.e., from register RB), bits 32:34 of the CR are set to 0b100.

Chapter 11. Legacy Integer Multiply-Accumulate Instructions [Category: Legacy Integer Multiply-Accumulate]

The *Legacy Integer Multiply-Accumulate* instructions with Rc=1 set the first three bits of CR Field 0 based on the 32-bit result, as described in Section 3.3.7, “Other Fixed-Point Instructions”.

The XO-form *Legacy Integer Multiply-Accumulate* instructions set SO and OV when OE=1 to reflect overflow of the 32-bit result.

Programming Note

Notice that CR Field 0 may not reflect the “true” (infinitely precise) result if overflow occurs.

RT0:31 ← undefined

```

The signed-integer halfword in bits 48:63 of register RA is multiplied by the signed-integer halfword in bits 32:47 of register RB.

The 32-bit signed-integer product is added to the signed-integer word in bits 32:63 of register RT.

The low-order 32 bits of the sum are placed into bits 32:63 of register RT.

The contents of bits 0:31 of register RT are undefined.

Appendix B. Densely Packed Decimal

The trailing significand field of the decimal floating-point data format is encoded using Densely Packed Decimal (DPD). DPD encoding is a compression technique which supports the representation of decimal integers of arbitrary length. Translation operates on three Binary Coded Decimal (BCD) digits at a time compressing the 12 bits into 10 bits with an algorithm that

can be applied or reversed using simple Boolean operations. In the following examples, a 3-digit BCD number is represented as (abcd)(efgh)(ijklm), a 10-bit DPD number is represented as (pqr)(stu)(v)(wxy), and the Boolean operations, & (AND), | (OR), and ¬ (NOT) are used.

B.1 BCD-to-DPD Translation

The translation from a 3-digit BCD number to a 10-bit DPD can be performed through the following Boolean operations.

$$\begin{aligned} p &= (f \& a \& i \& \neg e) \mid (j \& a \& \neg i) \mid (b \& \neg a) \\ q &= (g \& a \& i \& \neg e) \mid (k \& a \& \neg i) \mid (c \& \neg a) \\ r &= d \end{aligned}$$

$$\begin{aligned} s &= (j \& \neg a \& e \& \neg i) \mid (f \& \neg i \& \neg e) \mid \\ &\quad (f \& \neg a \& \neg e) \mid (e \& i) \\ t &= (k \& \neg a \& e \& \neg i) \mid (g \& \neg i \& \neg e) \mid \\ &\quad (g \& \neg a \& \neg e) \mid (a \& i) \\ u &= h \end{aligned}$$

$$v = a \mid e \mid i$$

$$\begin{aligned} w &= (\neg e \& j \& \neg i) \mid (e \& i) \mid a \\ x &= (\neg a \& k \& \neg i) \mid (a \& i) \mid e \\ y &= m \end{aligned}$$

Alternatively, the following table can be used to perform the translation. The most significant bit of the three BCD digits (left column) is used to select a specific 10-bit encoding (right column) of the DPD.

aei	pqr stu v wxy
000	bcd fgh 0 jkm
001	bcd fgh 1 00m
010	bcd jkh 1 01m
011	bcd 10h 1 11m
100	jkd fgh 1 10m
101	fgd 01h 1 11m
110	jkd 00h 1 11m
111	00d 11h 1 11m

The full translation of a 3-digit BCD number (000 - 999) to a 10-bit DPD is shown in Table 108 on page 617,

with the DPD entries shown in hexadecimal format. The BCD number is produced by replacing ‘_’ in the leftmost column with the corresponding digit along the top row. The table is split into two halves, with the right half being a continuation of the left half.

B.2 DPD-to-BCD Translation

The translation from a 10-bit DPD to a 3-digit BCD number can be performed through the following Boolean operations.

$$\begin{aligned} a &= (\neg s \& v \& w) \mid (t \& v \& w \& s) \mid (v \& w \& \neg x) \\ b &= (p \& s \& x \& \neg t) \mid (p \& \neg w) \mid (p \& \neg v) \\ c &= (q \& s \& x \& \neg t) \mid (q \& \neg w) \mid (q \& \neg v) \\ d &= r \end{aligned}$$

$$\begin{aligned} e &= (v \& \neg w \& x) \mid (s \& v \& w \& x) \mid \\ &\quad (\neg t \& v \& x \& w) \\ f &= (p \& t \& v \& w \& x \& \neg s) \mid (s \& \neg x \& v) \mid \\ &\quad (s \& \neg v) \\ g &= (q \& t \& w \& v \& x \& \neg s) \mid (t \& \neg x \& v) \mid \\ &\quad (t \& \neg v) \\ h &= u \end{aligned}$$

$$\begin{aligned} i &= (t \& v \& w \& x) \mid (s \& v \& w \& x) \mid \\ &\quad (v \& \neg w \& \neg x) \\ j &= (p \& \neg s \& \neg t \& w \& v) \mid (s \& v \& \neg w \& x) \mid \\ &\quad (p \& w \& \neg x \& v) \mid (w \& \neg v) \\ k &= (q \& \neg s \& \neg t \& v \& w) \mid (t \& v \& \neg w \& x) \mid \\ &\quad (q \& v \& w \& \neg x) \mid (x \& \neg v) \\ m &= y \end{aligned}$$

Alternatively, the following table can be used to perform the translation. A combination of five bits in the DPD encoding (leftmost column) are used to specify a translation to the 3-digit BCD encoding. Dashes (-) in the table are don't cares, and can be either one or zero.

vwkst	abcd	efgh	ijklm
0----	0pqr	0stu	0wxy
100--	0pqr	0stu	100y
101--	0pqr	100u	0sty
110--	100r	0stu	0pqy
11100	100r	100u	0pqy
11101	100r	0pqu	100y
11110	0pqr	100u	100y
11111	100r	100u	100y

The full translation of the 10-bit DPD to a 3-digit BCD number is shown in Table 109 on page 618. The 10-bit DPD index is produced by concatenating the 6-bit value shown in the left column with the 4-bit index along the top row, both represented in hexadecimal. The values in parentheses are non-preferred translations and are explained further in the following section.

B.3 Preferred DPD encoding

Translating from a 3-digit BCD number (1000 numbers) to a 10-bit DPD encoding (1024 combinations) leaves 24 redundant translations. The 24 redundant combinations are evenly assigned to eight BCD numbers and are shown in the following table, with the non-preferred encoding in parentheses. The preferred encoding is produced by translating a 3-digit BCD number with the translation table or Boolean operations shown in Section B.1. The redundant DPD encodings are all valid and will be correctly translated to their respective BCD value through the mechanisms provided in Section B.2. For decimal floating-point operations all DPD encodings are recognized as source operands.

DPD Code	BCD Value	DPD Code	BCD Value

return result
```

Appendix E. Assembler Extended Mnemonics

In order to make assembler language programs simpler to write and easier to understand, a set of extended mnemonics and symbols is provided that defines simple shorthand for the most frequently used forms of *Branch Conditional*, *Compare*, *Trap*, *Rotate and Shift*, and certain other instructions.

Assemblers should provide the extended mnemonics and symbols listed here, and may provide others.

E.1 Symbols

The following symbols are defined for use in instructions (basic or extended mnemonics) that specify a Condition Register field or a Condition Register bit. The first five (lt, ..., un) identify a bit number within a CR field. The remainder (cr0, ..., cr7) identify a CR field. An expression in which a CR field symbol is multiplied by 4 and then added to a bit-number-within-CR-field symbol and 32 can be used to identify a CR bit.

Symbol	Value	Meaning
lt	0	Less than
gt	1	Greater than
eq	2	Equal
so	3	Summary overflow
un	3	Unordered (after floating-point comparison)
cr0	0	CR Field 0
cr1	1	CR Field 1
cr2	2	CR Field 2
cr3	3	CR Field 3
cr4	4	CR Field 4
cr5	5	CR Field 5
cr6	6	CR Field 6
cr7	7	CR Field 7

The extended mnemonics in Sections E.2.2 and E.3 require identification of a CR bit: if one of the CR field symbols is used, it must be multiplied by 4 and added to a bit-number-within-CR-field (value in the range 0-3, explicit or symbolic) and 32. The extended mnemonics in Sections E.2.3 and E.5 require identification of a CR field: if one of the CR field symbols is used, it must *not* be multiplied by 4 or added to 32. (For the extended mnemonics in Section E.2.3, the bit number within the CR field is part of the extended mnemonic. The programmer identifies the CR field, and the Assembler does the multiplication and addition required to produce a CR bit number for the BI field of the underlying basic mnemonic.)

E.2 Branch Mnemonics

The mnemonics discussed in this section are variations of the *Branch Conditional* instructions.

Note: *bclr*, *bclrl*, *bcctr*, and *bcctrl* each serve as both a basic and an extended mnemonic. The Assembler will recognize a *bclr*, *bclrl*, *bcctr*, or *bcctrl* mnemonic with three operands as the basic form, and a *bclr*, *bclrl*, *bcctr*, or *bcctrl* mnemonic with two operands as the extended form. In the extended form the BH operand is omitted and assumed to be 0b00. Similarly, for all the extended mnemonics described in Sections E.2.2 - E.2.4 that devolve to any of these four basic mnemonics the BH operand can either be coded or omitted. If it is omitted it is assumed to be 0b00.

E.2.1 BO and BI Fields

The 5-bit BO and BI fields control whether the branch is taken. Providing an extended mnemonic for every possible combination of these fields would be neither useful nor practical. The mnemonics described in Sections E.2.2 - E.2.4 include the most useful cases. Other cases can be coded using a basic *Branch Conditional* mnemonic (*bc[l][a]*, *bclrl*, *bcctrl*) with the appropriate operands.

E.2.2 Simple Branch Mnemonics

Instructions using one of the mnemonics in Table 110 that tests a Condition Register bit specify the corresponding bit as the first operand. The symbols defined in Section E.1 can be used in this operand.

Notice that there are no extended mnemonics for relative and absolute unconditional branches. For these the basic mnemonics *b*, *ba*, *bl*, and *bla* should be used.

Branch Semantics	LR not Set				LR Set			
	<i>bc</i> Relative	<i>bca</i> Absolute	<i>bclr</i> To LR	<i>bcctr</i> To CTR	<i>bcl</i> Relative	<i>bcla</i> Absolute	<i>bclrl</i> To LR	<i>bcctrl</i> To CTR
Branch unconditionally	-	-	blr	bctr	-	-	blrl	bctrl
Branch if CR _{BI} =1	bt	bta	btlr	btctr	btl	btla	btlrl	btctrl
Branch if CR _{BI} =0	bf	bfa	bflr	bfctr	bfl	bfla	bflrl	bfctrl
Decrement CTR, branch if CTR nonzero	bdnz	bdnza	bdnzlr	-	bdnzl	bdnzla	bdnzlrl	-
Decrement CTR, branch if CTR nonzero and CR _{BI} =1	bdnzt	bdnzta	bdnztlr	-	bdnztl	bdnztla	bdnztlrl	-
Decrement CTR, branch if CTR nonzero and CR _{BI} =0	bdnzf	bdnzfa	bdnzflr	-	bdnzfl	bdnzfla	bdnzflrl	-
Decrement CTR, branch if CTR zero	bdz	bdza	bdzlr	-	bdzl	bdzla	bdzlrl	-
Decrement CTR, branch if CTR zero and CR _{BI} =1	bdzt	bdzta	bdztlr	-	bdztl	bdztle	bdztlrl	-
Decrement CTR, branch if CTR zero and CR _{BI} =0	bdzf	bdzfa	bdzflr	-	bdzfl	bdzfla	bdzflrl	-

Examples

1. Decrement CTR and branch if it is still nonzero (closure of a loop controlled by a count loaded into CTR).

```
bdnz target          (equivalent to: bc 16,0,target)
```

2. Same as (1) but branch only if CTR is nonzero and condition in CR0 is "equal".

```
bdnzt eq,target     (equivalent to: bc 8,2,target)
```

3. Same as (2), but "equal" condition is in CR5.

```
bdnzt 4×cr5+eq,target (equivalent to: bc 8,22,target)
```

4. Branch if bit 59 of CR is 0.

`bf 27,target` (equivalent to: `bc 4,27,target`)

5. Same as (4), but set the Link Register. This is a form of conditional “call”.

`bfl 27,target` (equivalent to: `bcl 4,27,target`)

E.2.3 Branch Mnemonics Incorporating Conditions

In the mnemonics defined in Table 111, the test of a bit in a Condition Register field is encoded in the mnemonic.

Instructions using the mnemonics in Table 111 specify the CR field as an optional first operand. One of the CR field symbols defined in Section E.1 can be used for this operand. If the CR field being tested is CR Field 0, this operand need not be specified unless the resulting basic mnemonic is *bclr[l]* or *bcctr[l]* and the BH operand is specified.

A standard set of codes has been adopted for the most common combinations of branch conditions.

Code	Meaning
lt	Less than
le	Less than or equal
eq	Equal
ge	Greater than or equal
gt	Greater than
nl	Not less than
ne	Not equal
ng	Not greater than
so	Summary overflow
ns	Not summary overflow
un	Unordered (after floating-point comparison)
nu	Not unordered (after floating-point comparison)

These codes are reflected in the mnemonics shown in Table 111.

Branch Semantics	LR not Set				LR Set			
	<i>bc</i> Relative	<i>bca</i> Absolute	<i>bclr</i> To LR	<i>bcctr</i> To CTR	<i>bcl</i> Relative	<i>bcla</i> Absolute	<i>bclrl</i> To LR	<i>bcctl</i> To CTR
Branch if less than	blt	blta	bltr	blctr	bltl	bltla	bltrl	blctr
Branch if less than or equal	ble	blea	blelr	blectr	blel	blela	blelr	blectr
Branch if equal	beq	beqa	beqlr	beqctr	beql	beqla	beqlr	beqctr
Branch if greater than or equal	bge	bgea	bgelr	bgectr	bgel	bgela	bgelr	bgectr
Branch if greater than	bgt	bgta	bgtr	bgctr	bgtl	bgtla	bgtr	bgctr
Branch if not less than	bnl	bnla	bnlrr	bnlctr	bnll	bnlla	bnlrr	bnlctr
Branch if not equal	bne	bnea	bnelr	bnecr	bnel	bnela	bnelr	bnecr
Branch if not greater than	bng	bnga	bnglr	bngctr	bngl	bngla	bnglr	bngctr
Branch if summary overflow	bso	bsoa	bsolr	bsoctr	bsol	bsola	bsolr	bsoctr
Branch if not summary overflow	bns	bnsa	bnslr	bnsctr	bns	bnsa	bnslr	bnsctr
Branch if unordered	bun	buna	bunlr	bunctr	bunl	bunla	bunlr	bunctr
Branch if not unordered	bnu	bnu	bnulr	bnuctr	bnul	bnula	bnulr	bnuctr

Examples

1. Branch if CR0 reflects condition “not equal”.

`bne target` (equivalent to: `bc 4,2,target`)

2. Same as (1), but condition is in CR3.

bne cr3,target (equivalent to: bc 4,14,target)

3. Branch to an absolute target if CR4 specifies “greater than”, setting the Link Register. This is a form of conditional “call”.

bgtla cr4,target (equivalent to: bcla 12,17,target)

4. Same as (3), but target address is in the Count Register.

bgtctrl cr4 (equivalent to: bcctrl 12,17,0)

E.2.4 Branch Prediction

Software can use the “at” bits of *Branch Conditional* instructions to provide a hint to the processor about the behavior of the branch. If, for a given such instruction, the branch is almost always taken or almost always not taken, a suffix can be added to the mnemonic indicating the value to be used for the “at” bits.

- + Predict branch to be taken (at=0b11)
- Predict branch not to be taken (at=0b10)

Such a suffix can be added to any *Branch Conditional* mnemonic, either basic or extended, that tests either the Count Register or a CR bit (but not both). Assemblers should use 0b00 as the default value for the “at” bits, indicating that software has offered no prediction.

Examples

1. Branch if CR0 reflects condition “less than”, specifying that the branch should be predicted to be taken.

blt+ target

2. Same as (1), but target address is in the Link Register and the branch should be predicted not to be taken.

bltlr-

E.3 Condition Register Logical Mnemonics

The *Condition Register Logical* instructions can be used to set (to 1), clear (to 0), copy, or invert a given Condition Register bit. Extended mnemonics are provided that allow these operations to be coded easily.

Operation	Extended Mnemonic	Equivalent to
Condition Register set	crset bx	creqv bx,bx,bx
Condition Register clear	crclr bx	crxor bx,bx,bx
Condition Register move	crmove bx,by	cror bx,by,by
Condition Register not	crnot bx,by	crnor bx,by,by

The symbols defined in Section E.1 can be used to identify the Condition Register bits.

Examples

1. Set CR bit 57.

```
crset 25          (equivalent to:  creqv 25,25,25)
```

2. Clear the SO bit of CR0.

```
crclr so         (equivalent to:  crxor 3,3,3)
```

3. Same as (2), but SO bit to be cleared is in CR3.

```
crclr 4×cr3+so   (equivalent to:  crxor 15,15,15)
```

4. Invert the EQ bit.

```
crnot eq,eq      (equivalent to:  crnor 2,2,2)
```

5. Same as (4), but EQ bit to be inverted is in CR4, and the result is to be placed into the EQ bit of CR5.

```
crnot 4×cr5+eq,4×cr4+eq  (equivalent to:  crnor 22,18,18)
```

E.4 Subtract Mnemonics

E.4.1 Subtract Immediate

Although there is no “Subtract Immediate” instruction, its effect can be achieved by using an Add Immediate instruction with the immediate operand negated. Extended mnemonics are provided that include this negation, making the intent of the computation clearer.

```
subi  Rx,Ry,value  (equivalent to:  addi  Rx,Ry,-value)
subis Rx,Ry,value  (equivalent to:  addis Rx,Ry,-value)
subic Rx,Ry,value  (equivalent to:  addic  Rx,Ry,-value)
subic. Rx,Ry,value (equivalent to:  addic. Rx,Ry,-value)
```

E.4.2 Subtract

The *Subtract From* instructions subtract the second operand (RA) from the third (RB). Extended mnemonics are provided that use the more “normal” order, in which the third operand is subtracted from the second. Both these mnemonics can be coded with a final “o” and/or “.” to cause the OE and/or Rc bit to be set in the underlying instruction.

```
sub  Rx,Ry,Rz      (equivalent to:  subf  Rx,Rz,Ry)
subc Rx,Ry,Rz      (equivalent to:  subfc Rx,Rz,Ry)
```

E.5 Compare Mnemonics

The L field in the fixed-point *Compare* instructions controls whether the operands are treated as 64-bit quantities or as 32-bit quantities. Extended mnemonics are provided that represent the L value in the mnemonic rather than requiring it to be coded as a numeric operand.

The BF field can be omitted if the result of the comparison is to be placed into CR Field 0. Otherwise the target CR field must be specified as the first operand. One of the CR field symbols defined in Section E.1 can be used for this operand.

Note: The basic *Compare* mnemonics of Power ISA are the same as those of POWER, but the POWER instructions have three operands while the Power ISA instructions have four. The Assembler will recognize a basic *Compare* mnemonic with three operands as the POWER form, and will generate the instruction with L=0. (Thus the Assembler must require that the BF field, which normally can be omitted when CR Field 0 is the target, be specified explicitly if L is.)

E.5.1 Doubleword Comparisons

Operation	Extended Mnemonic	Equivalent to
Compare doubleword immediate	cmpdi bf,ra,si	cmpi bf,1,ra,si
Compare doubleword	cmpd bf,ra,rb	cmp bf,1,ra,rb
Compare logical doubleword immediate	cmpldi bf,ra,ui	cmpli bf,1,ra,ui
Compare logical doubleword	cmpld bf,ra,rb	cmpl bf,1,ra,rb

Examples

1. Compare register Rx and immediate value 100 as unsigned 64-bit integers and place result into CR0.

```
cmpldi Rx,100          (equivalent to:  cmpli  0,1,Rx,100)
```

2. Same as (1), but place result into CR4.

```
cmpldi cr4,Rx,100     (equivalent to:  cmpli  4,1,Rx,100)
```

3. Compare registers Rx and Ry as signed 64-bit integers and place result into CR0.

```
cmpd Rx,Ry           (equivalent to:  cmp   0,1,Rx,Ry)
```

E.5.2 Word Comparisons

Operation	Extended Mnemonic	Equivalent to
Compare word immediate	cmpwi bf,ra,si	cmpi bf,0,ra,si
Compare word	cmpw bf,ra,rb	cmp bf,0,ra,rb
Compare logical word immediate	cmplwi bf,ra,ui	cmpli bf,0,ra,ui
Compare logical word	cmplw bf,ra,rb	cmpl bf,0,ra,rb

Examples

1. Compare bits 32:63 of register Rx and immediate value 100 as signed 32-bit integers and place result into CR0.

```
cmpwi Rx,100          (equivalent to:  cmpi  0,0,Rx,100)
```

2. Same as (1), but place result into CR4.

```
cmpwi cr4,Rx,100     (equivalent to:  cmpi  4,0,Rx,100)
```

3. Compare bits 32:63 of registers Rx and Ry as unsigned 32-bit integers and place result into CR0.

```
cmplw Rx,Ry          (equivalent to:  cmpl  0,0,Rx,Ry)
```

E.6 Trap Mnemonics

The mnemonics defined in Table 115 are variations of the *Trap* instructions, with the most useful values of TO represented in the mnemonic rather than specified as a numeric operand.

A standard set of codes has been adopted for the most common combinations of trap conditions.

Code	Meaning	TO encoding	<	>	=	< ^u	> ^u
lt	Less than	16	1	0	0	0	0
le	Less than or equal	20	1	0	1	0	0
eq	Equal	4	0	0	1	0	0
ge	Greater than or equal	12	0	1	1	0	0
gt	Greater than	8	0	1	0	0	0
nl	Not less than	12	0	1	1	0	0
ne	Not equal	24	1	1	0	0	0
ng	Not greater than	20	1	0	1	0	0
llt	Logically less than	2	0	0	0	1	0
lle	Logically less than or equal	6	0	0	1	1	0
lge	Logically greater than or equal	5	0	0	1	0	1
lgt	Logically greater than	1	0	0	0	0	1
lnl	Logically not less than	5	0	0	1	0	1
lng	Logically not greater than	6	0	0	1	1	0
u	Unconditionally with parameters	31	1	1	1	1	1
(none)	Unconditional	31	1	1	1	1	1

These codes are reflected in the mnemonics shown in Table 115.

Trap Semantics	64-bit Comparison		32-bit Comparison	
	<i>tdi</i> Immediate	<i>td</i> Register	<i>twi</i> Immediate	<i>tw</i> Register
Trap unconditionally	-	-	-	trap
Trap unconditionally with parameters	tdui	tdu	twui	twu
Trap if less than	tdlti	tdlt	twlti	twlt
Trap if less than or equal	tdlei	tdle	twlei	twle
Trap if equal	tdeqi	tdeq	tweqi	tweq
Trap if greater than or equal	tdgei	tdge	twgei	twge
Trap if greater than	tdgti	tdgt	twgti	twgt
Trap if not less than	tdnli	tdnl	twnli	twnl
Trap if not equal	tdnei	tdne	twnei	twne
Trap if not greater than	tdngi	tdng	twngi	twng
Trap if logically less than	tdllti	tdllt	twllti	twllt
Trap if logically less than or equal	tdllei	tdlle	twllei	twlle
Trap if logically greater than or equal	tdlgei	tdlge	twlgei	twlge
Trap if logically greater than	tdlgti	tdlgt	twlgti	twlgt
Trap if logically not less than	tdlnli	tdlnl	twlnli	twlnl
Trap if logically not greater than	tdlngi	tdlng	twlngi	twlng

Examples

1. Trap if register Rx is not 0.

tdnei Rx,0 (equivalent to: tdi 24,Rx,0)

2. Same as (1), but comparison is to register Ry.

tdne Rx,Ry (equivalent to: td 24,Rx,Ry)

3. Trap if bits 32:63 of register Rx, considered as a 32-bit quantity, are logically greater than 0x7FF.

twlgti Rx,0x7FF (equivalent to: twi 1,Rx,0x7FF)

4. Trap unconditionally.

trap (equivalent to: tw 31,0,0)

5. Trap unconditionally with immediate parameters Rx and Ry

tdu Rx,Ry (equivalent to: td 31,Rx,Ry)

E.7 Rotate and Shift Mnemonics

The *Rotate and Shift* instructions provide powerful and general ways to manipulate register contents, but can be difficult to understand. Extended mnemonics are provided that allow some of the simpler operations to be coded easily.

Mnemonics are provided for the following types of operation.

Extract Select a field of n bits starting at bit position b in the source register; left or right justify this field in the target register; clear all other bits of the target register to 0.

Insert Select a left-justified or right-justified field of n bits in the source register; insert this field starting at bit position b of the target register; leave other bits of the target register unchanged. (No extended mnemonic is provided for insertion of a left-justified field when operating on doublewords, because such an insertion requires more than one instruction.)

Rotate Rotate the contents of a register right or left n bits without masking.

Shift Shift the contents of a register right or left n bits, clearing vacated bits to 0 (logical shift).

Clear Clear the leftmost or rightmost n bits of a register to 0.

Clear left and shift left

Clear the leftmost b bits of a register, then shift the register left by n bits. This operation can be used to scale a (known nonnegative) array index by the width of an element.

E.7.1 Operations on Doublewords

All these mnemonics can be coded with a final “.” to cause the Rc bit to be set in the underlying instruction.

Operation	Extended Mnemonic	Equivalent to
Extract and left justify immediate	extldi ra,rs,n,b ($n > 0$)	rldicr ra,rs,b,n-1
Extract and right justify immediate	extrdi ra,rs,n,b ($n > 0$)	rldicl ra,rs,b+n,64-n
Insert from right immediate	insrdi ra,rs,n,b ($n > 0$)	rldimi ra,rs,64-(b+n),b
Rotate left immediate	rotldi ra,rs,n	rldicl ra,rs,n,0
Rotate right immediate	rotrdi ra,rs,n	rldicl ra,rs,64-n,0
Rotate left	rotld ra,rs,rb	rldcl ra,rs,rb,0
Shift left immediate	sldi ra,rs,n ($n < 64$)	rldicr ra,rs,n,63-n
Shift right immediate	srdi ra,rs,n ($n < 64$)	rldicl ra,rs,64-n,n
Clear left immediate	clrldi ra,rs,n ($n < 64$)	rldicl ra,rs,0,n
Clear right immediate	clrrdi ra,rs,n ($n < 64$)	rldicr ra,rs,0,63-n
Clear left and shift left immediate	clrldi ra,rs,b,n ($n \leq b < 64$)	rldicr ra,rs,n,b-n

Examples

1. Extract the sign bit (bit 0) of register Ry and place the result right-justified into register Rx.

extrdi Rx,Ry,1,0 (equivalent to: rldicl Rx,Ry,1,63)

2. Insert the bit extracted in (1) into the sign bit (bit 0) of register Rz.

insrdi Rz,Rx,1,0 (equivalent to: rldimi Rz,Rx,63,0)

3. Shift the contents of register Rx left 8 bits.

sldi Rx,Rx,8 (equivalent to: rldicr Rx,Rx,8,55)

4. Clear the high-order 32 bits of register Ry and place the result into register Rx.

clrldi Rx,Ry,32 (equivalent to: rldicl Rx,Ry,0,32)

E.7.2 Operations on Words

All these mnemonics can be coded with a final “.” to cause the Rc bit to be set in the underlying instruction. The operations as described above apply to the low-order 32 bits of the registers, as if the registers were 32-bit registers. The Insert operations either preserve the high-order 32 bits of the target register or place rotated data there; the other operations clear these bits.

Operation	Extended Mnemonic	Equivalent to
Extract and left justify immediate	extlwi ra,rs,n,b (n > 0)	rlwinm ra,rs,b,0,n-1
Extract and right justify immediate	extrwi ra,rs,n,b (n > 0)	rlwinm ra,rs,b+n,32-n,31
Insert from left immediate	inslwi ra,rs,n,b (n > 0)	rlwimi ra,rs,32-b,b,(b+n)-1
Insert from right immediate	insrwi ra,rs,n,b (n > 0)	rlwimi ra,rs,32-(b+n),b,(b+n)-1
Rotate left immediate	rotlwi ra,rs,n	rlwinm ra,rs,n,0,31
Rotate right immediate	rotrwi ra,rs,n	rlwinm ra,rs,32-n,0,31
Rotate left	rotlw ra,rs,rb	rlwnm ra,rs,rb,0,31
Shift left immediate	slwi ra,rs,n (n < 32)	rlwinm ra,rs,n,0,31-n
Shift right immediate	srwi ra,rs,n (n < 32)	rlwinm ra,rs,32-n,n,31
Clear left immediate	clrlwi ra,rs,n (n < 32)	rlwinm ra,rs,0,n,31
Clear right immediate	clrrwi ra,rs,n (n < 32)	rlwinm ra,rs,0,0,31-n
Clear left and shift left immediate	clrlslwi ra,rs,b,n (n ≤ b < 32)	rlwinm ra,rs,n,b-n,31-n

Examples

1. Extract the sign bit (bit 32) of register Ry and place the result right-justified into register Rx.

extrwi Rx,Ry,1,0 (equivalent to: rlwinm Rx,Ry,1,31,31)

2. Insert the bit extracted in (1) into the sign bit (bit 32) of register Rz.

insrwi Rz,Rx,1,0 (equivalent to: rlwimi Rz,Rx,31,0,0)

3. Shift the contents of register Rx left 8 bits, clearing the high-order 32 bits.

slwi Rx,Rx,8 (equivalent to: rlwinm Rx,Rx,8,0,23)

4. Clear the high-order 16 bits of the low-order 32 bits of register Ry and place the result into register Rx, clearing the high-order 32 bits of register Rx.

clrlwi Rx,Ry,16 (equivalent to: rlwinm Rx,Ry,0,16,31)

E.8 Move To/From Special Purpose Register Mnemonics

The *mtspr* and *mfspir* instructions specify a Special Purpose Register (SPR) as a numeric operand. Extended mnemonics are provided that represent the SPR in the mnemonic rather than requiring it to be coded as an operand.

Special Purpose Register	Move To SPR		Move From SPR	
	Extended	Equivalent to	Extended	Equivalent to

Examples

1. Copy the contents of register Rx to the XER.

mtxer Rx (equivalent to: mtspr 1,Rx)

2. Copy the contents of the LR to register Rx.

mflr Rx (equivalent to: mfspir Rx,8)

3. Copy the contents of register Rx to the CTR.

mtctr Rx (equivalent to: mtspr 9,Rx)

E.9 Miscellaneous Mnemonics

No-op

Many Power ISA instructions can be coded in a way such that, effectively, no operation is performed. An extended mnemonic is provided for the preferred form of no-op. If an implementation performs any type of run-time optimization related to no-ops, the preferred form is the no-op that will trigger this.

nop (equivalent to: ori 0,0,0)

For some uses of a no-op instruction, optimizations related to no-ops, such as removal from the execution stream, are not desirable. An extended mnemonic is provided for the executed form of no-op. This form of no-op will still consume execution resources.

xnop (equivalent to: xori 0,0,0)

Load Immediate

The *addi* and *addis* instructions can be used to load an immediate value into a register. Extended mnemonics are provided to convey the idea that no addition is being performed but merely data movement (from the immediate field of the instruction to a register).

Load a 16-bit signed immediate value into register Rx.

li Rx,value (equivalent to: addi Rx,0,value)

Load a 16-bit signed immediate value, shifted left by 16 bits, into register Rx.

lis Rx,value (equivalent to: addis Rx,0,value)

Load Address

This mnemonic permits computing the value of a base-displacement operand, using the **addi** instruction which normally requires separate register and immediate operands.

```
la    Rx,D(Ry)      (equivalent to:  addi    Rx,Ry,D)
```

The **la** mnemonic is useful for obtaining the address of a variable specified by name, allowing the Assembler to supply the base register number and compute the displacement. If the variable *v* is located at offset *Dv* bytes from the address in register *Rv*, and the Assembler has been told to use register *Rv* as a base for references to the data structure containing *v*, then the following line causes the address of *v* to be loaded into register *Rx*.

```
la    Rx,v          (equivalent to:  addi    Rx,Rv,Dv)
```

Move Register

Several Power ISA instructions can be coded in a way such that they simply copy the contents of one register to another. An extended mnemonic is provided to convey the idea that no computation is being performed but merely data movement (from one register to another).

The following instruction copies the contents of register *Ry* to register *Rx*. This mnemonic can be coded with a final “.” to cause the *Rc* bit to be set in the underlying instruction.

```
mr    Rx,Ry         (equivalent to:  or     Rx,Ry,Ry)
```

Complement Register

Several Power ISA instructions can be coded in a way such that they complement the contents of one register and place the result into another register. An extended mnemonic is provided that allows this operation to be coded easily.

The following instruction complements the contents of register *Ry* and places the result into register *Rx*. This mnemonic can be coded with a final “.” to cause the *Rc* bit to be set in the underlying instruction.

```
not   Rx,Ry         (equivalent to:  nor    Rx,Ry,Ry)
```

Move To/From Condition Register

This mnemonic permits copying the contents of the low-order 32 bits of a GPR to the Condition Register, using the same style as the **mfcrr** instruction.

```
mtrc  Rx            (equivalent to:  mtrcf  0xFF,Rx)
```

The following instructions may generate either the (old) **mtrcf** or **mfcrr** instructions or the (new) **mtocrf** or **mfocrf** instruction, respectively, depending on the target machine type assembler parameter.

```
mtcrf  FXM,Rx  
mfocrf  Rx
```

All three extended mnemonics in this subsection are being phased out. In future assemblers the form “mtrc Rx” may not exist, and the **mtrcf** and **mfcrr** mnemonics may generate the old form instructions (with bit 11 = 0) regardless of the target machine type assembler parameter, or may cease to exist.

Appendix F. Programming Examples

F.1 Multiple-Precision Shifts

This section gives examples of how multiple-precision shifts can be programmed.

A multiple-precision shift is defined to be a shift of an N-doubleword quantity (64-bit mode) or an N-word quantity (32-bit mode), where $N > 1$. The quantity to be shifted is contained in N registers. The shift amount is specified either by an immediate value in the instruction, or by a value in a register.

The examples shown below distinguish between the cases $N=2$ and $N > 2$. If $N=2$, the shift amount may be in the range 0 through 127 (64-bit mode) or 0 through 63 (32-bit mode), which are the maximum ranges supported by the *Shift* instructions used. However if $N > 2$, the shift amount must be in the range 0 through 63 (64-bit mode) or 0 through 31 (32-bit mode), in order for the examples to yield the desired result. The specific instance shown for $N > 2$ is $N=3$; extending those code sequences to larger N is straightforward, as is reducing

them to the case $N=2$ when the more stringent restriction on shift amount is met. For shifts with immediate shift amounts only the case $N=3$ is shown, because the more stringent restriction on shift amount is always met.

In the examples it is assumed that GPRs 2 and 3 (and 4) contain the quantity to be shifted, and that the result is to be placed into the same registers, except for the immediate left shifts in 64-bit mode for which the result is placed into GPRs 3, 4, and 5. In all cases, for both input and result, the lowest-numbered register contains the highest-order part of the data and highest-numbered register contains the lowest-order part. For non-immediate shifts, the shift amount is assumed to be in GPR 6. For immediate shifts, the shift amount is assumed to be greater than 0. GPRs 0 and 31 are used as scratch registers.

For $N > 2$, the number of instructions required is $2N-1$ (immediate shifts) or $3N-1$ (non-immediate shifts).

F.2 Floating-Point Conversions [Category: Floating-Point]

This section gives examples of how the *Floating-Point Conversion* instructions can be used to perform various conversions.

Warning: Some of the examples use the *fsel* instruction. Care must be taken in using *fsel* if IEEE compatibility is required, or if the values being tested can be NaNs or infinities; see Section F.3.4, “Notes” on page 648.

F.2.1 Conversion from Floating-Point Number to Floating-Point Integer

The full *convert to floating-point integer* function can be implemented with the sequence shown below, assuming the floating-point value to be converted is in FPR 1 and the result is returned in FPR 3.

```
mtfsb0    23           #clear VXCVI
fctid[z]  f3,f1        #convert to fx int
fcfid     f3,f3        #convert back again
mcrfs    7,5          #VXCVI to CR
bf       31,$+8       #skip if VXCVI was 0
fmr      f3,f1        #input was fp int
```

F.2.2 Conversion from Floating-Point Number to Signed Fixed-Point Integer Doubleword

The full *convert to signed fixed-point integer doubleword* function can be implemented with the sequence shown below, assuming the floating-point value to be converted is in FPR 1, the result is returned in GPR 3, and a doubleword at displacement “disp” from the address in GPR 1 can be used as scratch space.

```
fctid[z]  f2,f1        #convert to dword int
stfd     f2,disp(r1)  #store float
ld       r3,disp(r1)  #load dword
```

F.2.3 Conversion from Floating-Point Number to Unsigned Fixed-Point Integer Doubleword

The full *convert to unsigned fixed-point integer doubleword* function can be implemented with the sequence shown below, assuming the floating-point value to be converted is in FPR 1, the value 0 is in FPR 0, the value $2^{64}-2048$ is in FPR 3, the value 2^{63} is in FPR 4 and GPR 4, the result is returned in GPR 3, and a doubleword at displacement “disp” from the address in GPR 1 can be used as scratch space.

```
fsel     f2,f1,f1,f0   #use 0 if < 0
fsub     f5,f3,f1      #use max if > max
fsel     f2,f5,f2,f3
fsub     f5,f2,f4      #subtract  $2^{63}$ 
fcmpl   cr2,f2,f4     #use diff if  $\geq 2^{63}$ 
fsel     f2,f5,f5,f2
fctid[z] f2,f2        #convert to fx int
stfd     f2,disp(r1)  #store float
ld       r3,disp(r1)  #load dword
blt     cr2,$+8       #add  $2^{63}$  if input
add     r3,r3,r4      # was  $\geq 2^{63}$ 
```

F.2.4 Conversion from Floating-Point Number to Signed Fixed-Point Integer Word

The full *convert to signed fixed-point integer word* function can be implemented with the sequence shown below, assuming the floating-point value to be converted is in FPR 1, the result is returned in GPR 3, and a doubleword at displacement “disp” from the address in GPR 1 can be used as scratch space.

```
fctiw[z] f2,f1        #convert to fx int
stfd     f2,disp(r1)  #store float
lwa     r3,disp+4(r1) #load word algebraic
```

F.2.5 Conversion from Floating-Point Number to Unsigned Fixed-Point Integer Word

The full *convert to unsigned fixed-point integer word* function can be implemented with the sequence shown below, assuming the floating-point value to be converted is in FPR 1, the value 0 is in FPR 0, the value $2^{32}-1$ is in FPR 3, the result is returned in GPR 3, and a doubleword at displacement “disp” from the address in GPR 1 can be used as scratch space.

```
fsel    f2,f1,f1,f0    #use 0 if < 0
fsub    f4,f3,f1       #use max if > max
fsel    f2,f4,f2,f3
fctid[z] f2,f2         #convert to fx int
stfd    f2,disp(r1)   #store float
lwz     r3,disp+4(r1) #load word and zero
```

F.2.6 Conversion from Signed Fixed-Point Integer Doubleword to Floating-Point Number

The full *convert from signed fixed-point integer doubleword* function, using the rounding mode specified by $FPSCR_{RN}$, can be implemented with the sequence shown below, assuming the fixed-point value to be converted is in GPR 3, the result is returned in FPR 1, and a doubleword at displacement “disp” from the address in GPR 1 can be used as scratch space.

```
std     r3,disp(r1)   #store dword
lfd     f1,disp(r1)   #load float
fcfid   f1,f1         #convert to fp int
```

F.2.7 Conversion from Unsigned Fixed-Point Integer Doubleword to Floating-Point Number

The full *convert from unsigned fixed-point integer doubleword* function, using the rounding mode specified by $FPSCR_{RN}$, can be implemented with the sequence shown below, assuming the fixed-point value to be converted is in GPR 3, the value 2^{32} is in FPR 4, the result is returned in FPR 1, and two doublewords at displacement “disp” from the address in GPR 1 can be used as scratch space.

```
rldicl  r2,r3,32,32   #isolate high half
rldicl  r0,r3,0,32    #isolate low half
std     r2,disp(r1)   #store dword both
std     r0,disp+8(r1)
lfd     f2,disp(r1)   #load float both
lfd     f1,disp+8(r1)
fcfid   f2,f2         #convert each half to
fcfid   f1,f1         # fp int (exact result)
fmadd   f1,f4,f2,f1   #( $2^{32}$ ) $\times$ high + low
```

An alternative, shorter, sequence can be used if rounding according to $FSCPR_{RN}$ is desired and $FPSCR_{RN}$ specifies *Round toward +Infinity* or *Round toward -Infinity*, or if it is acceptable for the rounded answer to be either of the two representable floating-point integers nearest to the given fixed-point integer. In this case the full *convert from unsigned fixed-point integer doubleword* function can be implemented with the sequence shown below, assuming the value 2^{64} is in FPR 2.

```
std     r3,disp(r1)   #store dword
lfd     f1,disp(r1)   #load float
fcfid   f1,f1         #convert to fp int
fadd    f4,f1,f2       #add  $2^{64}$ 
fsel    f1,f1,f1,f4    # if r3 < 0
```

F.2.8 Conversion from Signed Fixed-Point Integer Word to Floating-Point Number

The full *convert from signed fixed-point integer word* function can be implemented with the sequence shown below, assuming the fixed-point value to be converted is in GPR 3, the result is returned in FPR 1, and a doubleword at displacement “disp” from the address in GPR 1 can be used as scratch space. (The result is exact.)

```
extsw   r3,r3         #extend sign
std     r3,disp(r1)   #store dword
lfd     f1,disp(r1)   #load float
fcfid   f1,f1         #convert to fp int
```

The following sequence can be used, assuming a word at the address in GPR 1 + GPR 2 can be used as scratch space.

```
stwx    r3,r1,r2      # store word
lfiwax  f1,r1,r2      # load float
fcfid   f1,f1         # convert to fp int
```

F.2.9 Conversion from Unsigned Fixed-Point Integer Word to Floating-Point Number

The full *convert from unsigned fixed-point integer word* function can be implemented with the sequence shown below, assuming the fixed-point value to be converted is in GPR 3, the result is returned in FPR 1, and a doubleword at displacement “disp” from the address in GPR 1 can be used as scratch space. (The result is exact.)

```
rldicl  r0,r3,0,32    #zero-extend
std     r0,disp(r1)   #store dword
lfd     f1,disp(r1)   #load float
fcfid   f1,f1         #convert to fp int
```

F.2.10 Unsigned Single-Precision BCD Arithmetic

addg6s can be used to add or subtract two BCD operands. In these examples it is assumed that r0 contains 0x666...666. (BCD data formats are described in Section 5.3 of Book I.)

Addition of the unsigned BCD operand in register RA to the unsigned BCD operand in register RB can be accomplished as follows.

```
add    r1,RA,r0
add    r2,r1,RB
addg6s RT,r1,RB
subf   RT,RT,r2 # RT = RA +BCD RB
```

Subtraction of the unsigned BCD operand in register RA from the unsigned BCD operand in register RB can be accomplished as follows. (In this example it is assumed that RB is not register 0.)

```
addi   r1,RB,1
nor    r2,RA,RA # one's complement of RA
add    r3,r1,r2
addg6s RT,r1,r2
subf   RT,RT,r3 # RT = RB -BCD RA
```

Additional instructions are needed to handle signed BCD operands, and BCD operands that occupy more than one register (e.g., unsigned BCD operands that have more than 16 decimal digits).

F.2.11 Signed Single-Precision BCD Arithmetic

Addition of the signed 15-digit BCD operand in register RA to the signed BCD operand in register RB can be accomplished as follows. If the signs of operands are different, then the operand of smaller magnitude is subtracted from the operand of larger magnitude and the sign of the larger operand is preserved; otherwise the operands are added and the sign is preserved.

The sign code is in the low order 4 bits of the operands and uses one of the standard encodings. (See Section 5.3 of Book I for a description of BCD and sign encodings.) This example assumes preferred sign option 1 (0b1100 is plus and 0b1101 is minus). For preferred sign option 2 (0b1111 is plus and 0b1101 is minus), replace the **xori** after the "SignedSub" label with "**xori RA,RA,2**".

Preserving the appropriate sign code is accomplished by zeroing the sign code of the other operand before performing a 16 digit BCD addition/subtraction. Other addends (ones complement or 6's) must leave the sign code position as zero.

(In this example r11 contains 0x6666 6666 6666 6660.)

SignedSub:

```
xori   RA,RA,1
```

SignedAdd:

```
xor    r5,RA,RB
andi.  r5,r5,15 # compare sign codes
cmpld  cr1,RA,RB # compare magnitudes
beq    cr0,samesign
ble    cr1,BminusA
```

```
# set up for RT = RA -BCD RB
nor    r9,RB,RB # one's complement of RB
addi   r10,RA,16 # generate the carry in
b      submag
```

BminusA:

```
# set up for RT = RB -BCD RA
nor    r9,RA,RA # one's complement of RA
addi   r10,RB,16 # generate the carry in
```

submag:

```
rldicr r9,r9,0,59 # remove the sign code
add    r8,r10,r9
addg6s RT,r10,r9
rldicr RT,RT,0,59 # remove generated 6 from
# sign position
```

```
subf   RT,RT,r8
b      done
```

samesign:

```
rldicr r8,RB,0,59 # remove the sign code
add    r10,RA,r11 # add 6's
add    r9,r10,r8
addg6s RT,r10,RB
subf   RT,RT,r9 # RT = RA +BCD RB
```

done:

F.2.12 Unsigned Extended-Precision BCD Arithmetic

Multiple precision BCD arithmetic requires additional code to add/subtract higher order digits and handle the carry between 16 digit groups. For example, the following sequence implements a 32-digit BCD add. In this example the contents of register R3 concatenated with the contents of R4 represent the first 32-digit operand and the contents of register R5 concatenated with the contents of R6 represents the second operand. The contents of register R3 concatenated with the contents of register R4 represents the result.

(In this example r0 contains 0x6666 6666 6666 6666.)

```
add    r10,R4,r0
addc   r9,r10,R6 # generate the carry
addg6s R4,r10,R6
subf   R4,R4,r9 # RT1 = RA1 +BCD RB1
```

```
addze  R5,R5 # propagate the carry
add    r10,R3,r0
add    r9,r10,R5
addg6s R3,r10,R5
subf   R3,R3,r9 # RT0 = RA0 +BCD RB0
```

Note that an extra instruction (**addze**) is required to propagate the carry so that the same value is used in the subsequent **add** and **addg6s**.

The following sequence implements a 32-digit BCD subtraction. In this example the first operand in R3 and R4 is subtracted from the 2nd operand in R5 and R6. The result is in R3 and R4.

```
addi    r10,R6,1
nor     r9,R4,R4    # one's complement of RA0
addc    r8,r10,r9   # Generate the carry
addg6s  R4,r10,r9
subf    R4,R4,r8    # RT1 = RB1 -BCD RA1

addze   r10,R5     # propagate the carry
nor     r9,R3,R3   # one's complement of RA0
add     r8,r10,r2
addg6s  R3,r10,r9
subf    R3,R3,r8   # RT0 = RB0 -BCD RA0
```

F.3 Floating-Point Selection [Category: Floating-Point]

This section gives examples of how the *Floating Select* instruction can be used to implement floating-point minimum and maximum functions, and certain simple forms of if-then-else constructions, without branching.

The examples show program fragments in an imaginary, C-like, high-level programming language, and the corresponding program fragment using *fsel* and other Power ISA instructions. In the examples, a, b, x, y, and z are floating-point variables, which are assumed to be

in FPRs fa, fb, fx, fy, and fz. FPR fs is assumed to be available for scratch space.

Additional examples can be found in Section F.2, “Floating-Point Conversions [Category: Floating-Point]” on page 644.

Warning: Care must be taken in using *fsel* if IEEE compatibility is required, or if the values being tested can be NaNs or infinities; see Section F.3.4.

F.3.1 Comparison to Zero

High-level language:	Power ISA:	Notes
if $a \geq 0.0$ then $x \leftarrow y$ else $x \leftarrow z$	<i>fsel</i> fx, fa, fy, fz	(1)
if $a > 0.0$ then $x \leftarrow y$ else $x \leftarrow z$	<i>fneg</i> fs, fa <i>fsel</i> fx, fs, fz, fy	(1, 2)
if $a = 0.0$ then $x \leftarrow y$ else $x \leftarrow z$	<i>fsel</i> fx, fa, fy, fz <i>fneg</i> fs, fa <i>fsel</i> fx, fs, fx, fz	(1)

F.3.2 Minimum and Maximum

High-level language:	Power ISA:	Notes
$x \leftarrow \min(a, b)$	<i>fsub</i> fs, fa, fb <i>fsel</i> fx, fs, fb, fa	(3, 4, 5)
$x \leftarrow \max(a, b)$	<i>fsub</i> fs, fa, fb <i>fsel</i> fx, fs, fa, fb	(3, 4, 5)

F.3.3 Simple if-then-else Constructions

High-level language:	Power ISA:	Notes
if $a \geq b$ then $x \leftarrow y$ else $x \leftarrow z$	<i>fsub</i> fs, fa, fb <i>fsel</i> fx, fs, fy, fz	(4, 5)
if $a > b$ then $x \leftarrow y$ else $x \leftarrow z$	<i>fsub</i> fs, fb, fa <i>fsel</i> fx, fs, fz, fy	(3, 4, 5)
if $a = b$ then $x \leftarrow y$ else $x \leftarrow z$	<i>fsub</i> fs, fa, fb <i>fsel</i> fx, fs, fy, fz <i>fneg</i> fs, fs <i>fsel</i> fx, fs, fx, fz	(4, 5)

F.3.4 Notes

The following Notes apply to the preceding examples and to the corresponding cases using the other three arithmetic relations (<, ≤, and ≠). They should also be considered when any other use of *fsel* is contemplated.

In these Notes, the “optimized program” is the Power ISA program shown, and the “unoptimized program” (not shown) is the corresponding Power ISA program that uses *fcmpu* and *Branch Conditional* instructions instead of *fsel*.

- The unoptimized program affects the VXSNaN bit of the FPSCR, and therefore may cause the system error handler to be invoked if the corresponding exception is enabled, while the optimized program does not affect this bit. This property of the optimized program is incompatible with the IEEE standard.
- The optimized program gives the incorrect result if a is a NaN.
- The optimized program gives the incorrect result if a and/or b is a NaN (except that it may give the correct result in some cases for the minimum and maximum functions, depending on how those functions are defined to operate on NaNs).
- The optimized program gives the incorrect result if a and b are infinities of the same sign. (Here it is assumed that Invalid Operation Exceptions are disabled, in which case the result of the subtraction is a NaN. The analysis is more complicated if Invalid Operation Exceptions are enabled, because in that case the target register of the subtraction is unchanged.)
- The optimized program affects the OX, UX, XX, and VXISI bits of the FPSCR, and therefore may cause the system error handler to be invoked if the corresponding exceptions are enabled, while the unoptimized program does not affect these bits. This property of the optimized program is incompatible with the IEEE standard.

F.4 Vector Unaligned Storage Operations [Category: Vector]

F.4.1 Loading a Unaligned Quadword Using Permute from Big-Endian Storage

The following sequence of instructions copies the unaligned quadword storage operand into VRT.

```
# Assumptions:
# Rb != 0 and contents of Rb = 0xB
lvx      Vhi,0,Rb      # load MSQ
lvsl     Vp,0,Rb       # set permute control vector
addi     Rb,Rb,16      # address of LSQ
lvx      Vlo,0,Rb      # load LSQ
perm     Vt,Vhi,Vlo,Vp # align the data
```

1.6.6	Variable Length Encoded (VLE) Instructions	658			

1.1 Definitions

The following definitions, in addition to those specified in Book I, are used in this Book. In these definitions, “*Load* instruction” includes the *Cache Management* and other instructions that are stated in the instruction descriptions to be “treated as a *Load*”, and similarly for “*Store* instruction”.

- **system**

A combination of processors, storage, and associated mechanisms that is capable of executing programs. Sometimes the reference to system includes services provided by the privileged software.

- **main storage**

The level of storage hierarchy in which all storage state is visible to all processors and mechanisms in the system.

- **primary cache**

The level of cache closest to the processor.

- **secondary cache**

After the primary cache, the next closest level of cache to the processor.

- **instruction storage**

The view of storage as seen by the mechanism that fetches instructions.

- **data storage**

The view of storage as seen by a *Load* or *Store* instruction.

- **program order**

The execution of instructions in the order required by the sequential execution model. (See Section 2.2 of Book I.) A *dcbz* instruction that modifies storage which contains instructions has the same effect with respect to the sequential execution model as a *Store* instruction as described there.)

- **storage location**

A contiguous sequence of one or more bytes in storage. When used in association with a specific instruction or the instruction fetching mechanism, the length of the sequence of one or more bytes is typically implied by the operation. In other uses, it may refer more abstractly to a group of bytes which share common storage attributes.

- **storage access**

An access to a storage location. There are three (mutually exclusive) kinds of storage access.

- data access

An access to the storage location specified by a *Load* or *Store* instruction, or, if the access is performed “out-of-order” (see Section 5.5 of Book III-S and Section 6.5 of Book III-E), an access to a storage location as if it were the storage location specified by a *Load* or *Store* instruction.

- instruction fetch

An access for the purpose of fetching an instruction.

- implicit access

An access by the processor for the purpose of address translation or reference and change recording (see Book III-S).

■ caused by, associated with**- caused by**

A storage access is said to be caused by an instruction if the instruction is a *Load* or *Store* and the access (data access) is to the storage location specified by the instruction.

- associated with

A storage access is said to be associated with an instruction if the access is for the purpose of fetching the instruction (instruction fetch), or is a data access caused by the instruction, or is an implicit access that occurs as a side effect of fetching or executing the instruction.

■ prefetched instructions

Instructions for which a copy of the instruction has been fetched from instruction storage, but the instruction has not yet been executed.

■ uniprocessor

A system that contains one processor.

■ multiprocessor

A system that contains two or more processors.

■ shared storage multiprocessor

A multiprocessor that contains some common storage, which all the processors in the system can access.

■ performed

A load or instruction fetch by a processor or mechanism (P1) is performed with respect to any processor or mechanism (P2) when the value to be returned by the load or instruction fetch can no longer be changed by a store by P2. A store by P1 is performed with respect to P2 when a load by P2 from the location accessed by the store will return the value stored (or a value stored subsequently). An instruction cache block invalidation by P1 is performed with respect to P2 when an instruction fetch by P2 will not be satisfied from the copy of

the block that existed in its instruction cache when the instruction causing the invalidation was executed, and similarly for a data cache block invalidation.

The preceding definitions apply regardless of whether P1 and P2 are the same entity.

■ page (virtual page)

2^n contiguous bytes of storage aligned such that the effective address of the first byte in the page is an integral multiple of the page size for which protection and control attributes are independently specifiable and for which reference and change status <S> are independently recorded.

■ block

The aligned unit of storage operated on by the *Cache Management* instructions. The size of an instruction cache block may differ from the size of a data cache block, and both sizes may vary between implementations. The maximum block size is equal to the minimum page size.

■ aligned storage access

A load or store is aligned if the address of the target storage location is a multiple of the size of the transfer effected by the instruction.

1.2 Introduction

The Power ISA User Instruction Set Architecture, discussed in Book I, defines storage as a linear array of bytes indexed from 0 to a maximum of $2^{64}-1$. Each byte is identified by its index, called its address, and each byte contains a value. This information is sufficient to allow the programming of applications that require no special features of any particular system environment. The Power ISA Virtual Environment Architecture, described herein, expands this simple storage model to include caches, virtual storage, and shared storage multiprocessors. The Power ISA Virtual Environment Architecture, in conjunction with services based on the Power ISA Operating Environment Architecture (see Book III) and provided by the operating system, permits explicit control of this expanded storage model. A simple model for sequential execution allows at most one storage access to be performed at a time and requires that all storage accesses appear to be performed in program order. In contrast to this simple model, the Power ISA specifies a relaxed model of storage consistency. In a multiprocessor system that allows multiple copies of a storage location, aggressive implementations of the architecture can permit intervals of time during which different copies of a storage location have different values. This chapter describes features of the Power ISA that enable programmers to write correct programs for this storage model.

1.3 Virtual Storage

The Power ISA system implements a virtual storage model for applications. This means that a combination of hardware and software can present a storage model that allows applications to exist within a “virtual” address space larger than either the effective address space or the real address space.

Each program can access 2^{64} bytes of “effective address” (EA) space, subject to limitations imposed by the operating system. In a typical Power ISA system, each program’s EA space is a subset of a larger “virtual address” (VA) space managed by the operating system.

Each effective address is translated to a real address (i.e., to an address of a byte in real storage or on an I/O device) before being used to access storage. The hardware accomplishes this, using the address translation mechanism described in Book III. The operating system manages the real (physical) storage resources of the system, by setting up the tables and other information used by the hardware address translation mechanism.

In general, real storage may not be large enough to map all the virtual pages used by the currently active applications. With support provided by hardware, the operating system can attempt to use the available real pages to map a sufficient set of virtual pages of the applications. If a sufficient set is maintained, “paging” activity is minimized. If not, performance degradation is likely.

The operating system can support restricted access to virtual pages (including read/write, read only, and no access; see Book III), based on system standards (e.g., program code might be read only) and application requests.

1.4 Single-copy Atomicity

An access is *single-copy atomic*, or simply *atomic*, if it is always performed in its entirety with no visible fragmentation. Atomic accesses are thus serialized: each happens in its entirety in some order, even when that order is not specified in the program or enforced between processors.

Vector storage accesses are not guaranteed to be atomic. The following other types of single-register accesses are always atomic:

- byte accesses (all bytes are aligned on byte boundaries)
- halfword accesses aligned on halfword boundaries
- word accesses aligned on word boundaries
- doubleword accesses aligned on doubleword boundaries (64-bit implementations only; see Section 1.2 of Book III-E<E>)

No other accesses are guaranteed to be atomic. For example, the access caused by the following instructions is not guaranteed to be atomic.

- any *Load* or *Store* instruction for which the operand is unaligned
- *lmw*, *stmw*, *lswi*, *lswx*, *stswi*, *stswx*
- *lfdp*, *lfdpx*, *stfdp*, *stfdpx*
- any *Cache Management* instruction

An access that is not atomic is performed as a set of smaller disjoint atomic accesses. The number and alignment of these accesses are implementation-dependent, as is the relative order in which they are performed. Accesses that are aligned on a doubleword boundary for *lfdp*, *lfdpx*, *stfdp*, and *stfdpx* are performed as a pair of disjoint atomic doubleword accesses.

The results for several combinations of loads and stores to the same or overlapping locations are described below.

1. When two processors execute atomic stores to locations that do not overlap, and no other stores are performed to those locations, the contents of those locations are the same as if the two stores were performed by a single processor.
2. When two processors execute atomic stores to the same storage location, and no other store is performed to that location, the contents of that location are the result stored by one of the processors.
3. When two processors execute stores that have the same target location and are not guaranteed to be atomic, and no other store is performed to that location, the result is some combination of the bytes stored by both processors.
4. When two processors execute stores to overlapping locations, and no other store is performed to those locations, the result is some combination of the bytes stored by the processors to the overlapping bytes. The portions of the locations that do not overlap contain the bytes stored by the processor storing to the location.
5. When a processor executes an atomic store to a location, a second processor executes an atomic load from that location, and no other store is performed to that location, the value returned by the load is the contents of the location before the store or the contents of the location after the store.
6. When a load and a store with the same target location can be executed simultaneously, and no other store is performed to that location, the value returned by the load is some combination of the contents of the location before the store and the contents of the location after the store.

1.5 Cache Model

A cache model in which there is one cache for instructions and another cache for data is called a “Harvard-style” cache. This is the model assumed by the Power ISA, e.g., in the descriptions of the *Cache Management* instructions in Section 4.3. Alternative cache models may be implemented (e.g., a “combined cache” model, in which a single cache is used for both instructions and data, or a model in which there are several levels of caches), but they support the programming model implied by a Harvard-style cache.

The processor is not required to maintain copies of storage locations in the instruction cache consistent with modifications to those storage locations (e.g., modifications caused by *Store* instructions).

A location in the data cache is considered to be modified in that cache if the location has been modified (e.g., by a *Store* instruction) and the modified data have not been written to main storage.

Cache Management instructions are provided so that programs can manage the caches when needed. For example, program management of the caches is needed when a program generates or modifies code that will be executed (i.e., when the program modifies data in storage and then attempts to execute the modified data as instructions). The *Cache Management* instructions are also useful in optimizing the use of memory bandwidth in such applications as graphics and numerically intensive computing. The functions performed by these instructions depend on the storage control attributes associated with the specified storage location (see Section 1.6, “Storage Control Attributes”).

The *Cache Management* instructions allow the program to do the following.

- invalidate the copy of storage in an instruction cache block (*icbi*)
- <E> provide a hint that an instruction will probably soon be accessed from a specified instruction cache block (*icbt*)
- provide a hint that the program will probably soon access a specified data cache block (*dcbt*, *dcbst*)
- <E> allocate a data cache block and set the contents of that block to zeros, but perform no operation if no write access is allowed to the data cache block (*dcba*)
- set the contents of a data cache block to zeros (*dcbz*)
- copy the contents of a modified data cache block to main storage (*dcbst*)
- copy the contents of a modified data cache block to main storage and make the copy of the block in the data cache invalid (*dcbf* or *dcbfl*<S>)

1.6 Storage Control Attributes

Some operating systems may provide a means to allow programs to specify the storage control attributes described in this section. Because the support provided for these attributes by the operating system may vary between systems, the details of the specific system being used must be known before these attributes can be used.

Storage control attributes are associated with units of storage that are multiples of the page size. Each storage access is performed according to the storage control attributes of the specified storage location, as described below. The storage control attributes are the following.

- Write Through Required
- Caching Inhibited
- Memory Coherence Required
- Guarded
- Endianness<E>
- Strong Access Order [Category: SAO]

These attributes have meaning only when an effective address is translated by the processor performing the storage access.

<E> Additional storage control attributes may be defined for some implementations. See Section 6.8 of Book III-E for additional information.

Programming Note

The Write Through Required and Caching Inhibited attributes are mutually exclusive because, as described below, the Write Through Required attribute permits the storage location to be in the data cache while the Caching Inhibited attribute does not.

Storage that is Write Through Required or Caching Inhibited is not intended to be used for general-purpose programming. For example, the *lbarx*, *lharx*, *lwarx*, *ldarx*, *stbcx*., *sthcx*., *stwcx*., and *stdcx*. instructions may cause the system data storage error handler to be invoked if they specify a location in storage having either of these attributes.

In the remainder of this section, “*Load* instruction” includes the *Cache Management* and other instructions that are stated in the instruction descriptions to be “treated as a *Load*” unless they are explicitly excluded, and similarly for “*Store* instruction”.

1.6.1 Write Through Required

A store to a Write Through Required storage location is performed in main storage. A Store instruction that specifies a location in Write Through Required storage may cause additional locations in main storage to be accessed. If a copy of the block containing the speci-

fied location is retained in the data cache, the store is also performed in the data cache. The store does not cause the block to be considered to be modified in the data cache.

In general, accesses caused by separate *Store* instructions that specify locations in Write Through Required storage may be combined into one access. Such combining does not occur if the *Store* instructions are separated by a *sync*, *eieio*<S>, or *mbar*<E> instruction.

1.6.2 Caching Inhibited

An access to a Caching Inhibited storage location is performed in main storage. A *Load* instruction that specifies a location in Caching Inhibited storage may cause additional locations in main storage to be accessed unless the specified location is also Guarded. An instruction fetch from Caching Inhibited storage may cause additional words in main storage to be accessed. No copy of the accessed locations is placed into the caches.

In general, non-overlapping accesses caused by separate *Load* instructions that specify locations in Caching Inhibited storage may be combined into one access, as may non-overlapping accesses caused by separate *Store* instructions that specify locations in Caching Inhibited storage. Such combining does not occur if the *Load* or *Store* instructions are separated by a *sync* or *mbar*<E> instruction. Combining may also occur among such accesses from multiple processors that share a common memory interface. No combining occurs if the storage is also Guarded.

Programming Note

None of the memory barrier instructions prevent the combining of accesses from different processors. The Guarded storage attribute must be used in combination with Caching Inhibited to prevent such combining.

1.6.3 Memory Coherence Required [Category: Memory Coherence]

An access to a Memory Coherence Required storage location is performed coherently, as follows.

Memory coherence refers to the ordering of stores to a single location. Atomic stores to a given location are *coherent* if they are serialized in some order, and no processor or mechanism is able to observe any subset of those stores as occurring in a conflicting order. This serialization order is an abstract sequence of values; the physical storage location need not assume each of the values written to it. For example, a processor may update a location several times before the value is written to physical storage. The result of a store operation

is not available to every processor or mechanism at the same instant, and it may be that a processor or mechanism observes only some of the values that are written to a location. However, when a location is accessed atomically and coherently by all processors and mechanisms, the sequence of values loaded from the location by any processor or mechanism during any interval of time forms a subsequence of the sequence of values that the location logically held during that interval. That is, a processor or mechanism can never load a “newer” value first and then, later, load an “older” value.

Memory coherence is managed in blocks called coherence *blocks*. Their size is implementation-dependent, but is larger than a word and is usually the size of a cache block.

For storage that is not Memory Coherence Required, software must explicitly manage memory coherence to the extent required by program correctness. The operations required to do this may be system-dependent.

Because the Memory Coherence Required attribute for a given storage location is of little use unless all processors that access the location do so coherently, in statements about Memory Coherence Required storage elsewhere in this document it is generally assumed that the storage has the Memory Coherence Required attribute for all processors that access it.

Programming Note

Operating systems that allow programs to request that storage not be Memory Coherence Required should provide services to assist in managing memory coherence for such storage, including all system-dependent aspects thereof.

In most systems the default is that all storage is Memory Coherence Required. For some applications in some systems, software management of coherence may yield better performance. In such cases, a program can request that a given unit of storage not be Memory Coherence Required, and can manage the coherence of that storage by using the *sync* instruction, the *Cache Management* instructions, and services provided by the operating system.

1.6.4 Guarded

A data access to a Guarded storage location is performed only if either (a) the access is caused by an instruction that is known to be required by the sequential execution model, or (b) the access is a load and the storage location is already in a cache. If the storage is also Caching Inhibited, only the storage location specified by the instruction is accessed; otherwise any storage location in the cache block containing the specified storage location may be accessed.

For the Server environment, instructions are not fetched from virtual storage that is Guarded. If the instruction addressed by the current instruction address is in such storage, the system instruction storage error handler may be invoked (see Section 6.5.5 of Book III-S).

Programming Note

In some implementations, instructions may be executed before they are known to be required by the sequential execution model. Because the results of instructions executed in this manner are discarded if it is later determined that those instructions would not have been executed in the sequential execution model, this behavior does not affect most programs.

This behavior does affect programs that access storage locations that are not “well-behaved” (e.g., a storage location that represents a control register on an I/O device that, when accessed, causes the device to perform an operation). To avoid unintended results, programs that access such storage locations should request that the storage be Guarded, and should prevent such storage locations from being in a cache (e.g., by requesting that the storage also be Caching Inhibited).

1.6.5 Endianness [Category: Embedded.Little-Endian]

The Endianness storage control attribute specifies the byte ordering (Big-Endian or Little-Endian) that is used when the storage location is accessed; see Section 1.10 of Book I.

1.6.6 Variable Length Encoded (VLE) Instructions

VLE storage is used to store VLE instructions. Instructions fetched from VLE storage are processed as VLE instructions. VLE storage must also be Big-Endian. Instructions fetched from VLE storage that is Little-Endian cause a Byte-ordering exception, and the system instruction storage error handler will be invoked.

The VLE attribute has no effect on data accesses. See Chapter 1 of Book VLE.

1.6.7 Strong Access Order [Category: SAO]

All accesses to storage with the Strong Access Order (SAO) attribute (referred to as *SAO storage*) will be performed using a set of ordering rules different from that of the weakly consistent model that is described in Section 1.7.1, “Storage Access Ordering”. These rules apply only to accesses that are caused by a *Load* or a *Store*, and not to accesses associated with those instructions. Furthermore, these rules do not apply to accesses that are caused by or associated with instructions that are stated in their descriptions to be “treated as a *Load*” or “treated as a *Store*.” The details are described below, from the programmer’s point of view. (The processor may deviate from these rules if the programmer cannot detect the deviation.) The SAO attribute is not intended to be used for general purpose programming. It is provided in a manner that is not fully independent of the other storage attributes. Specifically, it is only provided for storage that is Memory Coherence Required, but not Write Through Required, not Caching Inhibited, and not Guarded. See Section 5.8.2.1, “Storage Control Bit Restrictions”, in Book III-S for more details. Accesses to SAO storage are likely to be performed more slowly than similar accesses to non-SAO storage.

The order in which a processor performs storage accesses to SAO storage, the order in which those accesses are performed with respect to other processors and mechanisms, and the order in which those accesses are performed in main storage are the same except in the circumstances described in the following paragraph. The ordering rules for accesses performed by a single processor to SAO storage are as follows. Stores are performed in program order. When a store accesses data adjacent to that which is accessed by the next store in program order, the two storage accesses may be combined into a single larger access. Loads are performed in program order. When a load accesses data adjacent to that which is accessed by the next load in program order, the two storage accesses may be combined into a single larger access. Stores may not be performed before loads which precede them in program order. Loads may be performed before stores which precede them in program order, with the provision that a load which follows a store of the same datum (to the same address) must obtain a value which is no older (in consideration of the possibility of programs on other processors sharing the same storage) than the value stored by the preceding store.

When any given processor loads the datum it just stored, as described above, the load may be performed by the processor before the preceding store has been performed with respect to other processors and mechanisms, and in main storage. This may cause the processor to see its store earlier relative to stores performed by other processors than it is observed by

other processors and mechanisms, and than it is performed in memory. A direct consequence of this consideration is that although programs running on each processor will see the same sequence of accesses from any individual processor to SAO storage, each may in general see a different interleaving of the individual sequences. The memory barrier instructions may be used to establish stronger ordering, as described in Section 1.7.1, “Storage Access Ordering”, beginning with the third major bullet.

1.7 Shared Storage

This architecture supports the sharing of storage between programs, between different instances of the same program, and between processors and other mechanisms. It also supports access to a storage location by one or more programs using different effective addresses. All these cases are considered storage sharing. Storage is shared in blocks that are an integral number of pages.

When the same storage location has different effective addresses, the addresses are said to be *aliases*. Each application can be granted separate access privileges to aliased pages.

1.7.1 Storage Access Ordering

The Power ISA defines two models for the ordering of storage accesses: weakly consistent and strong access ordering. The predominant model is weakly consistent. This model provides an opportunity for improved performance over a model that has stronger consistency rules, but places the responsibility on the program to ensure that ordering or synchronization instructions are properly placed when storage is shared by two or more programs. Implementations which support Category SAO apply a stronger consistency model among accesses to SAO storage. The order between accesses to SAO storage and those performed using the weakly consistent model is characteristic of the weakly consistent model. The following description, through the second major bullet, applies only to the weakly consistent model. The corresponding description for SAO storage is found in Section 1.6.7, “Strong Access Order [Category: SAO]”. The rest of the description following the second bulleted item applies to both models.

The order in which the processor performs storage accesses, the order in which those accesses are performed with respect to another processor or mechanism, and the order in which those accesses are performed in main storage may all be different. Several means of enforcing an ordering of storage accesses are provided to allow programs to share storage with other programs, or with mechanisms such as I/O devices. These means are listed below. The phrase “to the extent required by the associated Memory Coherence Required attributes” refers to the Memory Coherence Required attribute, if any, associated with each access.

- If two *Store* instructions or two *Load* instructions specify storage locations that are both Caching Inhibited and Guarded, the corresponding storage accesses are performed in program order with respect to any processor or mechanism.
- If a *Load* instruction depends on the value returned by a preceding *Load* instruction (because the

value is used to compute the effective address specified by the second *Load*), the corresponding storage accesses are performed in program order with respect to any processor or mechanism to the extent required by the associated Memory Coherence Required attributes. This applies even if the dependency has no effect on program logic (e.g., the value returned by the first *Load* is ANDed with zero and then added to the effective address specified by the second *Load*).

- When a processor (P1) executes a *Synchronize*, *eieio*<S>, or *mbar*<E> instruction a *memory barrier* is created, which orders applicable storage accesses pairwise, as follows. Let A be a set of storage accesses that includes all storage accesses associated with instructions preceding the barrier-creating instruction, and let B be a set of storage accesses that includes all storage accesses associated with instructions following the barrier-creating instruction. For each applicable pair a_i, b_j of storage accesses such that a_i is in A and b_j is in B, the memory barrier ensures that a_i will be performed with respect to any processor or mechanism, to the extent required by the associated Memory Coherence Required attributes, before b_j is performed with respect to that processor or mechanism.

The ordering done by a memory barrier is said to be “cumulative” if it also orders storage accesses that are performed by processors and mechanisms other than P1, as follows.

- A includes all applicable storage accesses by any such processor or mechanism that have been performed with respect to P1 before the memory barrier is created.
- B includes all applicable storage accesses by any such processor or mechanism that are performed after a *Load* instruction executed by that processor or mechanism has returned the value stored by a store that is in B.

No ordering should be assumed among the storage accesses caused by a single instruction (i.e., by an instruction for which the access is not atomic), even if the accesses are to SAO storage, and no means are provided for controlling that order.

Programming Note

Because stores cannot be performed “out-of-order” (see Book III), if a *Store* instruction depends on the value returned by a preceding *Load* instruction (because the value returned by the *Load* is used to compute either the effective address specified by the *Store* or the value to be stored), the corresponding storage accesses are performed in program order. The same applies if *whether* the *Store* instruction is executed depends on a conditional *Branch* instruction that in turn depends on the value returned by a preceding *Load* instruction.

Because an *isync* instruction prevents the execution of instructions following the *isync* until instructions preceding the *isync* have completed, if an *isync* follows a conditional *Branch* instruction that depends on the value returned by a preceding *Load* instruction, the load on which the *Branch* depends is performed before any loads caused by instructions following the *isync*. This applies even if the effects of the “dependency” are independent of the value loaded (e.g., the value is compared to itself and the *Branch* tests the EQ bit in the selected CR field), and even if the branch target is the sequentially next instruction.

With the exception of the cases described above and earlier in this section, data dependencies and control dependencies do not order storage accesses. Examples include the following.

- If a *Load* instruction specifies the same storage location as a preceding *Store* instruction and the location is in storage that is not Caching Inhibited, the load may be satisfied from a “store queue” (a buffer into which the processor places stored values before presenting them to the storage subsystem), and not be visible to other processors and mechanisms. A consequence is that if a subsequent *Store* depends on the value returned by the *Load*, the two stores need not be performed in program order with respect to other processors and mechanisms.
- Because a *Store Conditional* instruction may complete before its store has been performed, a conditional *Branch* instruction that depends on the CRO value set by a *Store Conditional* instruction does

not order the *Store Conditional*s store with respect to storage accesses caused by instructions that follow the *Branch*.

- Because processors may predict branch target addresses and branch condition resolution, control dependencies (e.g., branches) do not order storage accesses except as described above. For example, when a subroutine returns to its caller the return address may be predicted, with the result that loads caused by instructions at or after the return address may be performed before the load that obtains the return address is performed.

Because processors may implement nonarchitected duplicates of architected resources (e.g., GPRs, CR fields, and the Link Register), resource dependencies (e.g., specification of the same target register for two *Load* instructions) do not order storage accesses.

Examples of correct uses of dependencies, *sync*, *lwsync*, and *eieio*<S> to order storage accesses can be found in Appendix B. “Programming Examples for Sharing Storage” on page 719.

Because the storage model is weakly consistent, the sequential execution model as applied to instructions that cause storage accesses guarantees only that those accesses appear to be performed in program order with respect to the processor executing the instructions. For example, an instruction may complete, and subsequent instructions may be executed, before storage accesses caused by the first instruction have been performed. However, for a sequence of atomic accesses to the same storage location, if the location is in storage that is Memory Coherence Required the definition of coherence guarantees that the accesses are performed in program order with respect to any processor or mechanism that accesses the location coherently, and similarly if the location is in storage that is Caching Inhibited.

Because accesses to storage that is Caching Inhibited are performed in main storage, memory barriers and dependencies on *Load* instructions order such accesses with respect to any processor or mechanism even if the storage is not Memory Coherence Required.

Programming Note

The first example below illustrates cumulative ordering of storage accesses preceding a memory barrier, and the second illustrates cumulative ordering of storage accesses following a memory barrier. Assume that locations X, Y, and Z initially contain the value 0.

Example 1:

Processor A:

stores the value 1 to location X

Processor B:

loads from location X obtaining the value 1, executes a **sync** instruction, then stores the value 2 to location Y

Processor C:

loads from location Y obtaining the value 2, executes a **sync** instruction, then loads from location X**Example 2:**

Processor A:

stores the value 1 to location X, executes a **sync** instruction, then stores the value 2 to location Y

Processor B:

loops loading from location Y until the value 2 is obtained, then stores the value 3 to location Z

Processor C:

loads from location Z obtaining the value 3, executes a **sync** instruction, then loads from location X

In both cases, cumulative ordering dictates that the value loaded from location X by processor C is 1.

word forms **lbarx**, **stbcx.**, **lharx**, **sthcx.**, **ldarx**, and **stdcx.** is the same except for obvious substitutions.

The **lwarx** instruction is a load from a word-aligned location that has two side effects. Both of these side effects occur at the same time that the load is performed.

1.7.2 Storage Ordering of I/O Accesses

A “coherence domain” consists of all processors and all interfaces to main storage. Memory reads and writes initiated by mechanisms outside the coherence domain are performed within the coherence domain in the order in which they enter the coherence domain and are performed as coherent accesses.

1.7.3 Atomic Update

The *Load And Reserve* and *Store Conditional* instructions together permit atomic update of a shared storage location. There are byte, halfword, word, and doubleword forms of each of these instructions. Described here is the operation of the word forms **lwarx** and **stwcx.**; operation of the byte, halfword, and double-

1. A reservation for a subsequent **stwcx.** instruction is created.
2. The memory coherence mechanism is notified that a reservation exists for the storage location specified by the **lwarx.**

The **stwcx.** instruction is a store to a word-aligned location that is conditioned on the existence of the reservation created by the **lwarx** and on whether the same storage location is specified by both instructions. To emulate an atomic operation with these instructions, it is necessary that both the **lwarx** and the **stwcx.** specify the same storage location.

A **stwcx.** performs a store to the target storage location only if the storage location specified by the **lwarx** that established the reservation has not been stored into by another processor or mechanism since the reservation was created. If the storage locations specified by the two instructions differ, the store is not necessarily performed except that if the Store Conditional Page Mobility category is supported and the storage locations are in different naturally aligned blocks of real storage whose size is the smallest real page size supported by the implementation, the store is not performed.

A **stwcx.** that performs its store is said to “succeed”.

Examples of the use of **lwarx** and **stwcx.** are given in Appendix B. “Programming Examples for Sharing Storage” on page 719.

A successful **stwcx.** to a given location may complete before its store has been performed with respect to other processors and mechanisms. As a result, a subsequent load or **lwarx** from the given location by another processor may return a “stale” value. However, a subsequent **lwarx** from the given location by the other processor followed by a successful **stwcx.** by that processor is guaranteed to have returned the value stored by the first processor’s **stwcx.** (in the absence of other stores to the given location).

If a *Store Conditional* instruction is used with a preceding *Load and Reserve* instruction that has a different storage operand length (e.g., **stwcx.** with **ldarx**), the reservation is cleared and it is undefined whether the store is performed.

Programming Note

The store caused by a successful **stwcx.** is ordered, by a dependence on the reservation, with respect to the load caused by the **lwarx** that established the reservation, such that the two storage accesses are performed in program order with respect to any processor or mechanism.

Programming Note

Before reassigning a virtual address to a different real page, privileged software may need to clear all processors’ reservations for the original real page in order to avoid a *Store Conditional* being successful only because the corresponding reservation for the original location is not cleared by a store to the new real page by some other processor or mechanism. This clearing of reservations is unnecessary on processors that support the Store Conditional Page Mobility category.

The Store Conditional Page Mobility category does not provide a mechanism for the *Store Conditional* instruction to detect that a virtual page has been moved to a new real page and back again to the original real page that was accessed by a *Load and Reserve* instruction. Privileged software that moves a virtual page could clear the reservation on the processor it is running on in order to ensure that a *Store Conditional* instruction executed by that processor does not succeed in this case. (The stores that occur naturally as part of moving the virtual page will cause any reservations, held by other processors, in the target real page to be lost.)

1.7.3.1 Reservations

The ability to emulate an atomic operation using **lwarx** and **stwcx.** is based on the conditional behavior of **stwcx.**, the reservation created by **lwarx**, and the clearing of that reservation if the target storage location is modified by another processor or mechanism before the **stwcx.** performs its store.

A reservation is held on an aligned unit of real storage called a reservation granule. The size of the reservation granule is 2^n bytes, where n is implementation-dependent but is always at least 4 (thus the minimum reservation granule size is a quadword) and, if the Store Conditional Page Mobility category is supported, where 2^n is not larger than the smallest real page size supported by the implementation. The reservation granule associated with effective address EA contains the real address to which EA maps. (“real_addr(EA)” in the RTL for the *Load And Reserve* and *Store Conditional* instructions stands for “real address to which EA maps”.) The reservation also has an associated length, which is equal to the storage operand length, in bytes, of the *Load and Reserve* instruction that established the reservation.

A processor has at most one reservation at any time. A reservation is established by executing a **lbarx**, **lharx**, **lwarx**, or **ldarx** instruction, as described below, and is lost (or may be lost, in the case of the fourth, fifth, sixth, seventh and ninth<E> item) if any of the following occur. Items 1-8 apply only if the relevant access is performed. (For example, an access that would ordinarily be caused by an instruction might not be per-

formed if the instruction causes the system error handler to be invoked.)

1. The processor holding the reservation executes another *lbarx*, *lharx*, *lwarx*, or *ldarx*: this clears the first reservation and establishes a new one.
2. The processor holding the reservation executes any *stbcx.*, *sthcx.*, *stwcx.*, or *stdcx.*, regardless of whether the specified address matches the address specified by the *lbarx*, *lharx*, *lwarx*, or *ldarx* that established the reservation, and regardless of whether the storage operand lengths of the two instructions are the same.
3. Some other processor executes a *Store*, *dcbz*, or *dcbzep*<E> that specifies a location in the same reservation granule.
4. Some other processor executes a *dcbtst*, *dcbtstep*<E>, or *dcbtstls*<E> that specifies a location in the same reservation granule: whether the reservation is lost is undefined. (For a *dcbtst* instruction that specifies a data stream, "location" in the preceding sentence includes all locations in the data stream.)
5. <E> Some other processor executes a *dcba* that specifies a location in the same reservation granule: the reservation is lost if the instruction causes the target block to be newly established in a data cache or to be modified; otherwise whether the reservation is lost is undefined.
6. <E> Some other processor executes a *dcbi* that specifies a location in the same reservation granule: the reservation may be lost if the instruction is treated as a *Store*.
7. <S> Any processor modifies a Reference or Change bit (see Book III-S) in the same reservation granule: whether the reservation is lost is undefined.
8. Some mechanism other than a processor modifies a storage location in the same reservation granule.
9. An interrupt (see Book III) occurs on the processor holding the reservation: for the Embedded environment, whether the reservation is lost is undefined. (For the Server environment the reservation is not lost. However, for both environments, system software invoked by interrupts may clear the reservation.)
10. Implementation-specific characteristics of the coherence mechanism cause the reservation to be lost.

Programming Note

One use of *lwarx* and *stwcx.* is to emulate a "Compare and Swap" primitive like that provided by the IBM System/370 Compare and Swap instruction; see Section B.1, "Atomic Update Primitives" on page 719. A System/370-style Compare and Swap checks only that the old and current values of the word being tested are equal, with the result that programs that use such a Compare and Swap to control a shared resource can err if the word has been modified and the old value subsequently restored. The combination of *lwarx* and *stwcx.* improves on such a Compare and Swap, because the reservation reliably binds the *lwarx* and *stwcx.* together. The reservation is always lost if the word is modified by another processor or mechanism between the *lwarx* and *stwcx.*, so the *stwcx.* never succeeds unless the word has not been stored into (by another processor or mechanism) since the *lwarx*.

Programming Note

In general, programming conventions must ensure that *lwarx* and *stwcx.* specify addresses that match; a *stwcx.* should be paired with a specific *lwarx* to the same storage location. Situations in which a *stwcx.* may erroneously be issued after some *lwarx* other than that with which it is intended to be paired must be scrupulously avoided. For example, there must not be a context switch in which the processor holds a reservation in behalf of the old context, and the new context resumes after a *lwarx* and before the paired *stwcx.*. The *stwcx.* in the new context might succeed, which is not what was intended by the programmer. Such a situation must be prevented by executing a *stbcx.*, *sthcx.*, *stwcx.*, or *stdcx.* that specifies a dummy writable aligned location as part of the context switch; see Section 6.4.3 of Book III-S and Section 7.5 of Book III-E.

Programming Note

Because the reservation is lost if another processor stores anywhere in the reservation granule, lock words (or bytes, halfwords, or doublewords) should be allocated such that few such stores occur, other than perhaps to the lock word itself. (Stores by other processors to the lock word result from contention for the lock, and are an expected consequence of using locks to control access to shared storage; stores to other locations in the reservation granule can cause needless reservation loss.) Such allocation can most easily be accomplished by allocating an entire reservation granule for the lock and wasting all but one word. Because reservation granule size is implementation-dependent, portable code must do such allocation dynamically.

Similar considerations apply to other data that are shared directly using *lwarx* and *stwcx*. (e.g., pointers in certain linked lists; see Section B.3, “List Insertion” on page 723).

Programming Note

The architecture does not include a “fairness guarantee”. In competing for a reservation, two processors can indefinitely lock out a third.

1.8 Instruction Storage

The instruction execution properties and requirements described in this section, including its subsections, apply only to instruction execution that is required by the sequential execution model.

In this section, including its subsections, it is assumed that all instructions for which execution is attempted are in storage that is not Caching Inhibited and (unless instruction address translation is disabled; see Book III-S) is not Guarded, and from which instruction fetching does not cause the system error handler to be invoked (e.g., from which instruction fetching is not prohibited by the “address translation mechanism” or the “storage protection mechanism”; see Book III).

1.7.3.2 Forward Progress

Forward progress in loops that use *lwarx* and *stwcx* is achieved by a cooperative effort among hardware, system software, and application software.

The architecture guarantees that when a processor executes a *lwarx* to obtain a reservation for location X and then a *stwcx* to store a value to location X, either

1. the *stwcx* succeeds and the value is written to location X, or
2. the *stwcx* fails because some other processor or mechanism modified location X, or
3. the *stwcx* fails because the processor’s reservation was lost for some other reason.

In Cases 1 and 2, the system as a whole makes progress in the sense that some processor successfully modifies location X. Case 3 covers reservation loss required for correct operation of the rest of the system. This includes cancellation caused by some other processor or mechanism writing elsewhere in the reservation granule, cancellation caused by the operating system in managing certain limited resources such as real storage, and cancellation caused by any of the other effects listed in see Section 1.7.3.1.

An implementation may make a forward progress guarantee, defining the conditions under which the system as a whole makes progress. Such a guarantee must specify the possible causes of reservation loss in Case 3. While the architecture alone cannot provide such a guarantee, the characteristics listed in Cases 1 and 2 are necessary conditions for any forward progress guarantee. An implementation and operating system can build on them to provide such a guarantee.

Programming Note

The results of attempting to execute instructions from storage that does not satisfy this assumption are described in Section 1.6.2 and Section 1.6.4 of this Book and in Book III.

For each instance of executing an instruction from location X, the instruction may be fetched multiple times.

The instruction cache is not necessarily kept consistent with the data cache or with main storage. It is the responsibility of software to ensure that instruction storage is consistent with data storage when such consistency is required for program correctness.

After one or more bytes of a storage location have been modified and before an instruction located in that storage location is executed, software must execute the appropriate sequence of instructions to make instruction storage consistent with data storage. Otherwise the result of attempting to execute the instruction is boundedly undefined except as described in Section 1.8.1, “Concurrent Modification and Execution of Instructions” on page 668.

Programming Note

Following are examples of how to make instruction storage consistent with data storage. Because the optimal instruction sequence to make instruction storage consistent with data storage may vary between systems, many operating systems will provide a system service to perform this function.

Case 1: The given program does not modify instructions executed by another program nor does another program modify the instructions executed by the given program.

Assume that location X previously contained the instruction A0; the program modified one or more bytes of that location such that, in data storage, the location contains the instruction A1; and location X is wholly contained in a single cache block. The following instruction sequence will make instruction storage consistent with data storage such that if the *isync* was in location X-4, the instruction A1 in location X would be executed immediately after the *isync*.

```
dcbst X      #copy the block to main storage
sync        #order copy before invalidation
icbi  X      #invalidate copy in instr cache
isync       #discard prefetched instructions
```

Case 2: One or more programs execute the instructions that are concurrently being modified by another program.

Assume program A has modified the instruction at location X and other programs are waiting for program A to signal that the new instruction is ready to execute. The following instruction sequence will make instruction storage consistent with data storage and then set a flag to indicate to the waiting programs that the new instruction can be executed.

```
li    r0,1    #put a 1 value in r0
dcbst X      #copy the block in main storage
sync      #order copy before invalidation
icbi  X      #invalidate copy in instr cache
sync      #order invalidation before store
        # to flag
stw r0,flag  #set flag indicating instruction
        # storage is now consistent
```

The following instruction sequence, executed by the waiting program, will prevent the waiting programs from executing the instruction at location X until location X in instruction storage is consistent with data storage, and then will cause any prefetched instructions to be discarded.

```
lwx  r0,flag #loop until flag = 1 (when 1 is
cmpwi r0,1  # loaded, location X in inst'n
bne  $-8    # storage is consistent with
        # location X in data storage)
isync      #discard any prefetched inst'ns
```

In the preceding instruction sequence any context synchronizing instruction (e.g., *rfd*) can be used instead of *isync*. (For Case 1 only *isync* can be used.)

For both cases, if two or more instructions in separate data cache blocks have been modified, the *dcbst* instruction in the examples must be replaced by a sequence of *dcbst* instructions such that each block containing the modified instructions is copied back to main storage. Similarly, for *icbi* the sequence must invalidate each instruction cache block containing a location of an instruction that was modified. The *sync* instruction that appears above between “*dcbst* X” and “*icbi* X” would be placed between the sequence of *dcbst* instructions and the sequence of *icbi* instructions.

1.8.1 Concurrent Modification and Execution of Instructions

The phrase “concurrent modification and execution of instructions” (CMODX) refers to the case in which a processor fetches and executes an instruction from instruction storage which is not consistent with data storage or which becomes inconsistent with data storage prior to the completion of its processing. This section describes the only case in which executing this instruction under these conditions produces defined results.

In the remainder of this section the following terminology is used.

- Location X is an arbitrary word-aligned storage location.
- X_0 is the value of the contents of location X for which software has made the location X in instruction storage consistent with data storage.
- X_1, X_2, \dots, X_n are the sequence of the first n values occupying location X after X_0 .
- X_n is the first value of X subsequent to X_0 for which software has again made instruction storage consistent with data storage.
- The “patch class” of instructions consists of the I-form *Branch* instruction ($b[l][a]$) and the preferred no-op instruction (*ori* 0,0,0).

If the instruction from location X is executed after the copy of location X in instruction storage is made consistent for the value X_0 and before it is made consistent for the value X_n , the results of executing the instruction are defined if and only if the following conditions are satisfied.

1. The stores that place the values X_1, \dots, X_n into location X are atomic stores that modify all four bytes of location X .
2. Each $X_i, 0 \leq i \leq n$, is a patch class instruction.
3. Location X is in storage that is Memory Coherence Required.

If these conditions are satisfied, the result of each execution of an instruction from location X will be the execution of some $X_i, 0 \leq i \leq n$. The value of the ordinate i associated with each value executed may be different and the sequence of ordinates i associated with a sequence of values executed is not constrained, (e.g., a valid sequence of executions of the instruction at location X could be the sequence X_i, X_{i+2} , then X_{i-1}). If these conditions are not satisfied, the results of each such execution of an instruction from location X are boundedly undefined, and may include causing inconsistent information to be presented to the system error handler.

Programming Note

An example of how failure to satisfy the requirements given above can cause inconsistent information to be presented to the system error handler is as follows. If the value X_0 (an illegal instruction) is executed, causing the system illegal instruction handler to be invoked, and before the error handler can load X_0 into a register, X_0 is replaced with X_1 , an *Add Immediate* instruction, it will appear that a legal instruction caused an illegal instruction exception.

Programming Note

It is possible to apply a patch or to instrument a given program without the need to suspend or halt the program. This can be accomplished by modifying the example shown in the Programming Note at the end of Section 1.8 where one program is creating instructions to be executed by one or more other programs.

In place of the *Store* to a flag to indicate to the other programs that the code is ready to be executed, the program that is applying the patch would replace a patch class instruction in the original program with a *Branch* instruction that would cause any program executing the *Branch* to branch to the newly created code. The first instruction in the newly created code must be an *isync*, which will cause any prefetched instructions to be discarded, ensuring that the execution is consistent with the newly created code. The instruction storage location containing the *isync* instruction in the patch area must be consistent with data storage with respect to the processor that will execute the patched code before the *Store* which stores the new *Branch* instruction is performed.

Programming Note

It is believed that all processors that comply with versions of the architecture that precede Version 2.01 support concurrent modification and execution of instructions as described in this section if the requirements given above are satisfied, and that most such processors yield boundedly undefined results if the requirements given above are not satisfied. However, in general such support has not been verified by processor testing. Also, one such processor is known to yield undefined results in certain cases if the requirements given above are not satisfied.

Chapter 2. Effect of Operand Placement on Performance

2.1 Instruction Restart 671

The placement (location and alignment) of operands in storage affects relative performance of storage accesses, and may affect it significantly. The best performance is guaranteed if storage operands are aligned. In order to obtain the best performance across the widest range of implementations, the programmer should assume the performance model described in Figure 1 with respect to the placement of storage operands for the Embedded environment. For the Server environment, Figure 1 applies for Big-Endian byte ordering, and Little-Endian byte ordering. Performance of storage accesses varies depending on the following:

1. Operand Size
2. Operand Alignment
3. Crossing no boundary
4. Crossing a cache block boundary
5. Crossing a virtual page boundary

The *Move Assist* instructions have no alignment requirements.

Operand		Boundary Crossing		
Size	Byte Align.	None	Cache Block	Virtual Page ²
Integer				
8 Byte	8	optimal	-	-
	4	good	good	good
	<4	good	good	good
4 Byte	4	optimal	-	-
	<4	good	good	good
2 Byte	2	optimal	-	-
	<2	good	good	good
1 Byte	1	optimal	-	-
<i>lmw</i> , <i>stmw</i>	4	good	good	good
	<4	poor	poor	poor
string		good	good	good
Float				
<i>lfdp</i> , <i>lfdpx</i> , <i>stfdp</i> , <i>stfdpx</i>	16	optimal	-	-
	<16	poor	poor	poor
8 Byte	8	optimal	-	-
	4	good	good	poor
	<4	poor	poor	poor
4 Byte	4	optimal	-	-
	<4	poor	poor	poor
Vector				
any	any	optimal ³	-	-
¹ If an instruction causes an access that is not atomic and any portion of the operand is in storage that is Write Through Required or Caching Inhibited, performance is likely to be poor. ² If the storage operand spans two virtual pages that have different storage control attributes or, in the Server environment, spans two segments, performance is likely to be poor. ³ The storage operands for Vector instructions are all assumed to be aligned (see Section 6.4 of Book I).				

Figure 1. Performance effects of storage operand placement

I

2.1 Instruction Restart

In this section, “*Load* instruction” includes the *Cache Management* and other instructions that are stated in the instruction descriptions to be “treated as a *Load*”, and similarly for “*Store* instruction”.

The following instructions are never restarted after having accessed any portion of the storage operand (unless the instruction causes a “Data Address Breakpoint match”, for which the corresponding rules are given in Book III).

1. A *Store* instruction that causes an atomic access and, for the Embedded environment, accesses storage that is Guarded
2. A *Load* instruction that causes an atomic access to storage that is Guarded and, for the Server environment, is also Caching Inhibited.

Any other *Load* or *Store* instruction may be partially executed and then aborted after having accessed a portion of the storage operand, and then re-executed (i.e., restarted, by the processor or the operating system). If an instruction is partially executed, the contents of registers are preserved to the extent that the correct result will be produced when the instruction is re-executed. Additional restrictions on the partial execution of instructions are described in Section 6.6 of Book III-S and Section 7.7 of Book III-E.

Programming Note

In order to ensure that the contents of registers are preserved to the extent that a partially executed instruction can be re-executed correctly, the registers that are preserved must satisfy the following conditions. For any given instruction, zero or more of the conditions applies.

- For a fixed-point *Load* instruction that is not a multiple or string form, or for an *eciwx* instruction, if RT=RA or RT=RB then the contents of register RT are not altered.
- For an update form *Load* or *Store* instruction, the contents of register RA are not altered.

Programming Note

There are many events that might cause a *Load* or *Store* instruction to be restarted. For example, a hardware error may cause execution of the instruction to be aborted after part of the access has been performed, and the recovery operation could then cause the aborted instruction to be re-executed.

When an instruction is aborted after being partially executed, the contents of the instruction pointer indicate that the instruction has not been executed, however, the contents of some registers may have been altered and some bytes within the storage operand may have been accessed. The following are examples of an instruction being partially executed and altering the program state even though it appears that the instruction has not been executed.

1. *Load Multiple*, *Load String*: Some registers in the range of registers to be loaded may have been altered.
2. Any *Store* instruction, ***dcbz***: Some bytes of the storage operand may have been altered.

Chapter 3. Management of Shared Resources

3.1	Program Priority Registers	675
3.2	“or” Instruction	676

The facilities described in this section provide the means to control the use of resources that are shared with other processors.

3.1 Program Priority Registers

The Program Priority Register (PPR) is a 64-bit register that controls the program’s priority. The PPR provides access to the full 64-bit PPR, and the Program Priority Register 32-bit (PPR32) provides access to the upper 32 bits of the PPR. The Embedded environment only provides access to PPR32. The layouts of the PPR and PPR32 are shown in Figure 2.

PPR [Category: Server]:

///	PRI	///	???	///	???
0	11	14	26	32	44
63					

PPR32 [Category: Phased-In]

///	PRI	///	???
32	43	46	58 63

Bit(s) **Description**

11:13 **Program Priority (PRI)**
(PPR32_{43:45})

010 low
011 medium low (normal)
100 medium

If other values are written to this field, the PRI field is not changed. (See Section 4.3.4 of Book III-S for additional information.)

26:31 Implementation-specific
(PPR32_{58:63})

44:63 implementation-specific

All other fields are reserved.

Figure 2. Program Priority Register

Programming Note

The ability to access the low-order half of the PPR (and thus the use of *mfppr* and *mtppr*) might be phased out in a future version of the architecture.

Programming Note

By setting the PRI field, a programmer may be able to improve system throughput by causing system resources to be used more efficiently.

E.g., if a program is waiting on a lock (see Section B.2), it could set low priority, with the result that more processor resources would be diverted to the program that holds the lock. This diversion of resources may enable the lock-holding program to complete the operation under the lock more quickly, and then relinquish the lock to the waiting program.

Programming Note

or Rx,Rx,Rx can be used to modify the PRI field; see Section 3.2.

Programming Note

When the system error handler is invoked, the PRI field may be set to an undefined value.

3.2 “or” Instruction

Setting the PPR

The *or Rx,Rx,Rx* (see Book I) instruction can be used to set PPR_{PRI} as shown in Figure 3. *or Rx,Rx,Rx* does not set PPR_{PRI} .

Rx	PPR_{PRI}	Priority
1	010	low
6	011	medium low (normal)
2	100	medium

Figure 3. Priority levels for *or Rx,Rx,Rx*

The following forms of *or Rx,Rx,Rx* provide hints about usage of shared processor resources.

“or” Shared Resource Hints

or 27,27,27

This form of **or** provides a hint that performance will probably be improved if shared resources dedicated to the executing processor are released for use by other processors.

or 29,29,29

This form of **or** provides a hint that performance will probably be improved if shared resources dedicated to the executing processor are released until all outstanding storage accesses to caching-inhibited storage have been completed.

or 30,30,30

This form of **or** provides a hint that performance will probably be improved if shared resources dedicated to the executing processor are released until all outstanding storage accesses to cacheable storage for which the data is not in the cache have been completed.

Extended Mnemonics:

Additional extended mnemonics for the **or** hints:

Extended:	Equivalent to:
yield	or 27,27,27
mdoio	or 29,29,29
mdoom	or 30,30,30

Programming Note

Warning: Other forms of *or Rx,Rx,Rx* that are not described in this section may also cause program priority to change. Use of these forms should be avoided except when software explicitly intends to alter program priority. If a no-op is needed, the preferred no-op (*ori 0,0,0*) should be used.

Chapter 4. Storage Control Instructions

4.1 Parameters Useful to Application Programs	677	4.4.1 Instruction Synchronize Instruction	693
4.2 Data Stream Control Register (DSCR) [Category: Stream]	678	4.4.2 Load and Reserve and Store Conditional Instructions.	693
4.3 Cache Management Instructions	679	4.4.2.1 64-Bit Load and Reserve and Store Conditional Instructions [Category: 64-Bit]	699
4.3.1 Instruction Cache Instructions	680	4.4.3 Memory Barrier Instructions.	701
4.3.2 Data Cache Instructions	681	4.4.4 Wait Instruction.	704
4.3.2.1 Obsolete Data Cache Instructions [Category: Vector.Phased-Out]	692		
4.4 Synchronization Instructions.	693		

4.1 Parameters Useful to Application Programs

It is suggested that the operating system provide a service that allows an application program to obtain the following information.

1. The virtual page sizes
2. Coherence block size
3. Reservation granule size
4. An indication of the cache model implemented (e.g., Harvard-style cache, combined cache)
5. Instruction cache size
6. Data cache size
7. Instruction cache block size
8. Data cache block size
9. Instruction cache associativity
10. Data cache associativity
11. Number of stream IDs supported for the stream variant of *dcbt*
12. Factors for converting the Time Base to seconds

If the caches are combined, the same value should be given for an instruction cache attribute and the corresponding data cache attribute.

4.2 Data Stream Control Register (DSCR) [Category: Stream]

The layout of the Data Stream Control Register (DSCR) is shown in Figure 4 below. See Section 4.3.2 for information on streams.

Figure 4. Data Stream Control Register

Bits	Name	Description
59	SNSE	<p>Stride-N Stream Enable</p> <p>This bit enables the hardware detection and initiation of load and store streams that have a stride greater than a single cache block. Such store streams are detected only when SSE is also one.</p>
60	SSE	<p>Store Stream Enable</p> <p>This bit enables hardware detection and initiation of store streams.</p>
61:63	DPFD	<p>Default Prefetch Depth</p> <p>This field supplies a prefetch depth for hardware-detected streams and for software-defined streams for which a depth of zero is specified or for which <i>dcbt/dcbtst</i> with TH=1010 is <i>not</i> used in their description. Values and their meanings are as follows.</p> <ul style="list-style-type: none"> 0 default (LPCR_{DPFD}) 1 none 2 shallowest 3 shallow 4 medium 5 deep 6 deeper 7 deepest

The contents of the DSCR affect how a processor handles hardware-detected and software-defined data streams.

A move to the DSCR causes all active and nascent data streams to cease to exist.

Access to this SPR is privileged; see Book III.

Programming Note

The SNSE and SSE fields do not affect the initiation of streams specified using the *dcbt* and *dcbtst* instructions.

Note that even when SNSE is not set, hardware may detect Stride-N streams in intervals when they access elements that map to sequential cache blocks.

Programming Note

The contents of the DSCR are intended to be managed by application programs. Access to the DSCR is privileged because, when the DSCR was added to the architecture, adding it as non-privileged would have been incompatible with the application binary interface (ABI) of some operating systems. Operating systems will provide a service that allows application programs to manage the contents of the DSCR.

4.3 Cache Management Instructions

The *Cache Management* instructions obey the sequential execution model except as described in Section 4.3.1.

In the instruction descriptions the statements “this instruction is treated as a *Load*” and “this instruction is treated as a *Store*” mean that the instruction is treated as a *Load (Store)* from (to) the addressed byte with respect to address translation, the definition of program order on page 653, storage protection, reference and change recording<S>, and the storage access ordering described in Section 1.7.1 and is treated as a *Read (Write)* from (to) the addressed byte with respect to debug events unless otherwise specified. (See Book III-E.)

Programming Note

Accesses that are caused by or associated with *Cache Management* instructions that are “treated as a *Load*” or “treated as a *Store*” are not subject to the special ordering rules described for SAO storage. These accesses are always performed in accordance with the weakly consistent storage model.

Some *Cache Management* instructions contain a CT field that is used to specify a cache level within a cache hierarchy or a portion of a cache structure to which the instruction is to be applied. The correspondence between the CT value specified and the cache level is shown below.

CT Field Value	Cache Level
0	Primary Cache
2	Secondary Cache

CT values not shown above may be used to specify implementation-dependent cache levels or implementation-dependent portions of a cache structure.

4.3.1 Instruction Cache Instructions

Instruction Cache Block Invalidate X-form

icbi RA, RB

0	31	///	RA	RB	982	/
	6		11	16	21	31

Let the effective address (EA) be the sum (RAI0)+(RB).

If the block containing the byte addressed by EA is in storage that is Memory Coherence Required and a block containing the byte addressed by EA is in the instruction cache of any processors, the block is invalidated in those instruction caches.

If the block containing the byte addressed by EA is in storage that is not Memory Coherence Required and the block is in the instruction cache of this processor, the block is invalidated in that instruction cache.

The function of this instruction is independent of whether the block containing the byte addressed by EA is in storage that is Write Through Required or Caching Inhibited.

This instruction is treated as a *Load* (see Section 4.3), except that reference and change recording<S> need not be done.

Special Registers Altered:

None

Programming Note

Because the instruction is treated as a *Load*, the effective address is translated using translation resources that are used for data accesses, even though the block being invalidated was copied into the instruction cache based on translation resources used for instruction fetches (see Book III).

Programming Note

The invalidation of the specified block need not have been performed with respect to the processor executing the *icbi* instruction until a subsequent *isync* instruction has been executed by that processor. No other instruction or event has the corresponding effect.

Instruction Cache Block Touch X-form

icbt CT, RA, RB

[Category: Embedded]

0	31	/	CT	RA	RB	22	/
	6	7	11	16	21	31	

Let the effective address (EA) be the sum (RAI0)+(RB).

If CT=0, this instruction provides a hint that the program will probably soon execute code from the addressed location.

If CT≠0, the operation performed by this instruction is implementation-dependent, except that the instruction is treated as a no-op for values of CT that are not implemented.

The hint is ignored if the block is Caching Inhibited.

This instruction is treated as a *Load* (see Section 4.3), except that the system instruction storage error handler is not invoked.

Special Registers Altered:

None

4.3.2 Data Cache Instructions

The Data Cache instructions control various aspects of the data cache.

TH field in the *dcbt* and *dcbtst* instructions

Described below are the TH field values for the *dcbt* and *dcbtst* instructions. For all TH field values which are not listed, the hint provided by the instruction is undefined.

TH=0b00000

If TH=0b00000, the *dcbt/dcbtst* instruction provides a hint that the program will probably soon access the block containing the byte addressed by EA.

TH=0b00000 - 0b00111

[Category: Cache Specification]

In addition to the hint specified above for the TH field value of 0b00000, an additional hint is provided indicating that placement of the block in the cache specified by the TH field might also improve performance. The correspondence between each value of the TH field and the cache to be specified is the same as the correspondence between each value the CT field and the cache to be specified as defined in Section 4.3. The hints corresponding to values of the TH field not supported by the implementation are undefined.

TH=0b01000 - 0b01111 [Category: Stream]

The *dcbt/dcbtst* instructions provide hints regarding a sequence of accesses to data elements, or indicate the expected use thereof. Such a sequence is called a “data stream”, and a *dcbt/dcbtst* instruction in which TH is set to one of these values is said to be a “data stream variant” of *dcbt/dcbtst*. In the remainder of this section, “data stream” may be abbreviated to “stream”.

A data stream to which a program may perform *Load* accesses is said to be a “load data stream”, and is described using the data stream variants of the *dcbt* instruction. A data stream to which a program may perform *Store* accesses is said to be a “store data stream”, and is described using the data stream variants of the *dcbtst* instruction.

When, and how often, effective addresses for a data stream are translated is implementation-dependent.

Each data element is associated with a *unit* of storage, which is the aligned 128-byte location in storage that contains the first byte of the element. The data stream variants may be used to specify the address of the beginning of the data stream, the displacement (stride) between the first byte of successive elements, and the number of unique units of storage that are associated with all of the data elements. If the stride is specified, both the stride and the address of the first element are specified at 4 byte granularity. If the stride is not speci-

fied, the address of the first element is the address of the first unit.

Programming Note

The architecture does not provide a way to specify the size of the data elements that compose a stream. An implementation may assume some fixed size for all data elements. As a result, depending on the offset, stride, and size (and in particular whether the elements are aligned), the implementation may reduce the latency for accessing only a portion of some of the elements. A future version of the architecture may enable the specification of element size to avoid this limitation.

Each such data stream is associated, by software, with a stream ID, which is a resource that the processor uses to distinguish the data stream from other such data streams. The number of stream IDs is an implementation-dependent value in the range 1:16. Stream IDs are numbered sequentially starting from 0.

The encodings of the TH field and of the corresponding EA values are as follows. In the EA layout diagrams, fields shown as “/”s are reserved. These reserved fields are treated in the same manner as the corresponding case for instruction fields (see Section 1.3.3 of Book I). If a reserved value is specified for a defined EA field, or if a TH value is specified that is not explicitly defined below, the hint provided by the instruction is undefined.

TH Description

01000 The *dcbt/dcbtst* instruction provides a hint that describes certain attributes of a data stream, and may indicate that the program will probably soon access the stream.

The EA is interpreted as follows.

EATRUNC	D	UG	/	ID
0	57	59	60	63

Bit(s) Description

0:56 **EATRUNC**

High-order 57 bits of the effective address of the first element of the data stream. (i.e., the effective address of the first unit of the stream is EATRUNC || ⁷0)

57 **Direction (D)**

0 Subsequent elements have increasing addresses.

1 Subsequent elements have decreasing addresses.

58 **Unlimited/GO** (UG)

- 0 No information is provided by the UG field.
- 1 The number of elements in the data stream is unlimited, the elements are adjacent to each other, the program's need for each element of the stream is not likely to be transient, and the program will probably soon access the stream.

59 Reserved

60:63 **Stream ID** (ID)

Stream ID to use for this data stream.

01010 The ***dcbt/dcbtst*** instruction provides a hint that describes certain attributes of a data stream, or indicates that the program will probably soon access data streams that have been described using data stream variants of the ***dcbt/dcbtst*** instruction, or will probably no longer access such data streams.

The EA is interpreted as follows. If GO=1 and S≠0b00 the hint provided by the instruction is undefined; the remainder of this instruction description assumes that this combination is not used.

///	GO	S	/	DEP	//	UNITCNT	T	U	/	ID
0	32	35	36	39	47	57	59	60	63	

Bit(s) Description

0:31 Reserved

32 **GO**

- 0 No information is provided by the GO field.
- 1 For ***dcbt***, the program will probably soon access all nascent load and store data streams that have been completely described, and will probably no longer access all other nascent load and store data streams. All other fields of the EA are ignored. ("Nascent" and "completely described" are defined below.) For ***dcbtst***, this field value holds no meaning and is treated as though it were zero.

33:34 **Stop** (S)

- 00 No information is provided by the S field.
- 01 Reserved
- 10 The program will probably no longer access the data stream (if any) associated with the specified

stream ID. (All other fields of the EA except the ID field are ignored.)

- 11 For ***dcbt***, the program will probably no longer access the load and store data streams associated with all stream IDs. (All other fields of the EA are ignored.) For ***dcbtst***, this field value holds no meaning, and is treated as though it were 0b00.

35 Reserved

36:38 **Depth** (DEP)

The DEP field provides a relative estimate of how many elements ahead of the point of stream use the latency-reducing actions should go. This value reflects a comparison of the rate of consumption of the elements of the data stream and the latency to bring an arbitrary element of the stream into cache. The values are as follows.

- 0 default = DSCR_{D_{DPFD}}
- 1 none
- 2 shallowest
- 3 shallow
- 4 medium
- 5 deep
- 6 deeper
- 7 deepest

39:46 Reserved

47:56 **UNITCNT**

Number of units in data stream.

57 **Transient** (T)

If T=1, the program's need for each element of the data stream is likely to be transient (i.e., the time interval during which the program accesses the element is likely to be short).

58 **Unlimited** (U)

If U=1, the number of units in the data stream is unlimited (and the UNITCNT field is ignored).

59 Reserved

60:63 **Stream ID** (ID)

Stream ID to use for this data stream (GO=0 and S=0b00), or stream ID associated with the data stream which the program will probably no longer access(S=0b10).

Programming Note

To maximize the utility of the Depth control mechanism, the architecture provides a hierarchy of three ways to program it. In the server environment, the DPFID field in the LPCR is used by the provisory/firmware to set a safe or appropriate default depth for unaware operating systems and applications. (The corresponding default in the embedded environment is implementation specific.) The DPFID field in the DSCR may be initialized by the aware OS and overwritten by an application via the OS-provided service when per stream control is unnecessary or unaffordable. The DEP field in the EA specification when TH=0b01010 may be used by the application to specify the depth on a per-stream basis.

The number of elements ahead of the point of stream use indicated by a given depth value may differ across implementations, as may the latency to bring a given element into the cache. To achieve optimum performance, some experimentation with different depth values may be necessary.

01011 The *dcbt/dcbtst* instruction provides a hint that describes certain attributes of a data stream.

The EA is interpreted as follows.

///	STRIDE	OFFSET	//	ID
0	32	50	56	60 63

Bit(s) Description

0:31 Reserved

32:49 Stride

The displacement, in words, between the first byte of successive elements in the stream. The effective address of the Nth element in the stream is

$$(N-1) \times \text{STRIDE} \times 4$$

greater than or less than the effective address of the first element of the stream, depending on the direction specified for the stream.

50 Reserved

51:55 Offset

The word-offset of the first element of the stream in its unit (i.e., the effective address of the first element of the stream is (EATRUNC || OFFSET || 0b00)).56:59Reserved

60:63 **Stream ID (ID)**

Stream ID to use for this data stream.

Programming Note

A program should use a *dcbt/dcbtst* instruction with TH=0b01011 only when the stride is larger than 128 bytes. Otherwise, consecutive units will be accessed, so the additional stream information has no benefit.

If the specified stream ID value is greater than m-1, where m is the number of stream IDs provided by the implementation, and either (a) TH=0b01000 or TH=0b01011, or (b) TH=0b01010 with GO=0 and S≠0b11, no hint is provided by the instruction.

The following terminology is used to describe the state of a data stream. Except as described in the paragraph after the next paragraph, the state of a data stream at a given time is determined by the most recently provided hint(s) for the stream.

- A data stream for which only descriptive hints have been provided (by *dcbt/dcbtst* instructions with TH=0b01000 and UG=0, TH=0b01010 and GO=0 and S=0b00, and/or with TH=0b01011) is said to be “nascent”. A nascent data stream for which all relevant descriptive hints have been provided (by the *dcbt/dcbtst* usages listed in the preceding sentence) is considered to be “completely described”. The order of descriptive hints with respect to one another is unimportant.
- A data stream for which a hint has been provided (by a *dcbt/dcbtst* instruction with TH=0b01000 and UG=1 or *dcbt* with TH=0b01010 and GO=1) that the program will probably soon access it is said to be “active”.
- A data stream that is either nascent or active is considered to “exist”.
- A data stream for which a hint has been provided (e.g., by a *dcbt* instruction with TH=0b01010 and S≠0b00) that the program will probably no longer access it is considered no longer to exist.

The hint provided by a *dcbt/dcbtst* instruction with TH=0b01000 and UG=1 implicitly includes a hint that the program will probably no longer access the data stream (if any) previously associated with the specified stream ID. The hint provided by a *dcbt/dcbtst* instruction with TH=0b01000 and UG=0, or with TH=0b01010 and GO=0 and S=0b00, or with TH=0b01011 implicitly includes a hint that the program will probably no longer access the *active* data stream (if any) previously associated with the specified stream ID.

If a data stream is specified without using a *dcbt/dcbtst* instruction with TH=0b01010 and GO=0 and S=0b00, then the number of elements in the stream is unlimited, and the program’s need for each element of the stream is not likely to be transient. If a data stream is specified without using a *dcbt/dcbtst* instruction with

TH=0b01011, then the stream will access consecutive units of storage.

Interrupts (see Book III) cause all existing data streams to cease to exist. In addition, depending on the implementation, certain conditions and events may cause an existing data stream to cease to exist; for example, in some implementations an existing data stream ceases to exist when it comes to the end of a page.

Programming Note

To obtain the best performance across the widest range of implementations that support the data stream variants of *dcbt/dcbtst*, the programmer should assume the following model when using those variants.

- The processor's response to a hint that the program will probably soon access a given data stream is to take actions that reduce the latency of accesses to the first few elements of the stream. (Such actions may include prefetching cache blocks into levels of the storage hierarchy that are "near" the processor.) Thereafter, as the program accesses each successive element of the stream, the processor takes latency-reducing actions for additional elements of the stream, pacing these actions with the program's accesses (i.e., taking the actions for only a limited number of elements ahead of the element that the program is currently accessing).

The processor's response to a hint that the program will probably no longer access a given data stream, or to the cessation of existence of a data stream, is to stop taking latency-reducing actions for the stream.

- A data stream having finite length ceases to exist when the latency-reducing actions have been taken for all elements of the stream.
- If the program ceases to need a given data stream before having accessed all elements of the stream (always the case for streams having unlimited length), performance may be improved if the program then provides a hint that it will no longer access the stream (e.g., by executing the appropriate *dcbt* instruction with TH=0b01010 and S≠0b00).

- At each level of the storage hierarchy that is "near" the processor, elements of a data stream that is specified as transient are most likely to be replaced. As a result, it may be desirable to stagger addresses of streams (choose addresses that map to different cache congruence classes) to reduce the likelihood that an element of a transient stream will be replaced prior to being accessed by the program.
- Processors that comply with versions of the architecture that do not support the TH field at all treat TH = 0b01000, 0b01010, and 0b01011 as if TH = 0b00000.
- A single set of stream IDs is shared between the *dcbt* and *dcbtst* instructions.
- On some implementations, data streams that are not specified by software may be detected by the processor. Such data streams are called "hardware-detected data streams". On some such implementations, data stream resources (resources that are used primarily to support data streams) are shared between software-specified data streams and hardware-detected data streams. On these latter implementations, the programming model includes the following.
 - Software-specified data streams take precedence over hardware-detected data streams in use of data stream resources.
 - The processor's response to a hint that the program will probably no longer access a given data stream, or to the cessation of existence of a data stream, includes releasing the associated data stream resources, so that they can be used by hardware-detected data streams.

Programming Note

This Programming Note describes several aspects of using the data stream variants of the *dcbt* and *dcbtst* instructions.

- A non-transient data stream having unlimited length and which will access consecutive units in storage can be completely specified, including providing the hint that the program will probably soon access it, using one *dcbt* instruction. The corresponding specification for a data stream having other attributes requires two or three *dcbt/dcbtst* instructions to describe the stream and one additional *dcbt* instruction to start the stream. However, one *dcbt* instruction with TH=0b01010 and GO=1 can apply to a set of the data streams described in the preceding sentence, so the corresponding specification for n such data streams requires 2×n to 3×n *dcbt/dcbtst* instructions plus one *dcbt* instruction. (There is no need to execute a *dcbt/dcbtst* instruction with TH=0b01010 and S=0b10 for a given stream ID before using the stream ID for a new data stream; the implicit portion of the hint provided by *dcbt/dcbtst* instructions that describe data streams suffices.)
- If it is desired that the hint provided by a given *dcbt/dcbtst* instruction be provided in program order with respect to the hint provided by another *dcbt/dcbtst* instruction, the two instructions must be separated by an *eieio*<S> (or *sync*) instruction. For example, if a *dcbt* instruction with TH=0b01010 and GO=1 is intended to indicate that the program will probably soon access nascent data streams described (completely) by preceding *dcbt/dcbtst* instructions, and is intended *not* to indicate that the program will probably soon access nascent data streams described (completely) by following *dcbt/dcbtst* instructions, an *eieio*<S> (or *sync*) instruction must separate the *dcbt* instruction with GO=1 from the preceding *dcbt/dcbtst* instructions, and another *eieio*<S> (or *sync*) instruction must separate that *dcbt* instruction from the following *dcbt/dcbtst* instructions.
- In practice, the second *eieio*<S> (or *sync*) described above can sometimes be omitted. For example, if the program consists of an outer loop that contains the *dcbt/dcbtst* instructions and an inner loop that contains the *Load* or *Store* instructions that access the data streams, the characteristics of the inner loop and of the implementation's branch prediction mechanisms may make it highly unlikely that hints corresponding to a given iteration of the outer loop will be provided out of program order with respect to hints corresponding to the previous iteration of the outer loop. (Also, any providing of hints out of program order affects only performance, not program correctness.)
- To mitigate the effects of interrupts on data streams, it may be desirable to specify a given "logical" data stream as a sequence of shorter, component data streams. Similar considerations apply to conditions and events that, depending on the implementation, may cause an existing data stream to cease to exist; for example, in some implementations an existing data stream ceases to exist when it comes to the end of a virtual page.
- If it is desired to specify data streams without regard to the number of stream IDs provided by the implementation, stream IDs should be assigned to data streams in order of decreasing stream importance (stream ID 0 to the most important stream, stream ID 1 to the next most important stream, etc.). This order ensures that the hints for the most important data streams will be provided.

TH=0b10000

If TH=0b10000, the *dcbt* instruction provides a hint that the program will probably soon load from the block containing the byte addressed by EA, and that the program's need for the block will be transient (i.e. the time interval during which the program accesses the block is likely to be short).

Programming Note

The processor's response to the hint that access to the block will be transient is to prefetch data into the cache hierarchy in a way that minimizes the displacement of data that has not been identified as transient.

Data Cache Block Allocate**X-form**

[Category: Embedded]

dcba RA,RB

31	///	RA	RB	758	/
----	-----	----	----	-----	---

0	6	11	16	21	31
---	---	----	----	----	----

Let the effective address (EA) be the sum (RAI0)+(RB).

This instruction provides a hint that the program will probably soon store into a portion of the block and the contents of the rest of the block are not meaningful to the program. The contents of the block are undefined when the instruction completes. The hint is ignored if the block is Caching Inhibited.

This instruction is treated as a *Store* (see Section 4.3) except that the instruction is treated as a no-op if execution of the instruction would cause the system data storage error handler to be invoked.

Special Registers Altered:

None

Data Cache Block Touch

X-form

dcbt RA, RB, TH [Category: Server]
 dcbt TH, RA, RB [Category: Embedded]

0	31	TH	RA	RB	278	/
	6	11	16	21		31

Let the effective address (EA) be the sum (RAI0)+(RB).

The **dcbt** instruction provides a hint that describes a block or data stream to which the program may perform a *Load* access. The instruction is also used to indicate imminent access or end of access to described load and store data streams. A hint that the program will probably soon load from a given storage location is ignored if the location is Caching Inhibited or Guarded<S>.

The only operation that is “caused” by the **dcbt** instruction is the providing of the hint. The actions (if any) taken by the processor in response to the hint are not considered to be “caused by” or “associated with” the **dcbt** instruction (e.g., **dcbt** is considered not to cause any data accesses). No means are provided by which software can synchronize these actions with the execution of the instruction stream. For example, these actions are not ordered by the memory barrier created by a **sync** instruction.

The **dcbt** instruction may complete before the operation it causes has been performed.

The nature of the hint depends, in part, on the value of the TH field, as specified at the beginning of this section. If TH≠0b01010 and TH≠0b01011, this instruction is treated as a *Load* (see Section 4.3), except that the system data storage error handler is not invoked, and reference and change recording-<S> need not be done.

Special Registers Altered:

None

Extended Mnemonics:

Extended mnemonics are provided for the *Data Cache Block Touch* instruction so that it can be coded with the TH value as the last operand for all categories, and so that the transient hint can be specified without coding the TH field explicitly.

Extended:	Equivalent to:
dcbtct RA, RB, TH	dcbt for TH values of 0b00000 - 0b00111; other TH values are invalid.
dcbt ds RA, RB, TH	dcbt for TH values of 0b00000 or 0b01000 - 0b01111; other TH values are invalid.
dcbt tt RA, RB	dcbt for TH value of 0b10000

Programming Notes

New programs should avoid using the ***dcbt*** and ***dcbtst*** mnemonics; one of the extended mnemonics should be used exclusively.

<S> If the ***dcbt*** mnemonic is used with only two operands, the TH operand is assumed to be 0b00000.

Processors that comply with versions of the architecture that precede Version 2.01 do not necessarily ignore the hint provided by ***dcbt*** and ***dcbtst*** if the specified block is in storage that is Guarded <S> and not Caching Inhibited.

Programming Note

See the Programming Notes at the beginning of this section.

Data Cache Block Touch for Store X-form

dcbtst RA, RB, TH [Category: Server]
dcbtst TH, RA, RB [Category: Embedded]

31	TH	RA	RB	246	/
0	6	11	16	21	31

Let the effective address (EA) be the sum (RA10)+(RB).

The ***dcbtst*** instruction provides a hint that describes a block or data stream to which the program may perform a *Store* access, or indicates the expected use thereof. A hint that the program will soon store to a given storage location is ignored if the location is Caching Inhibited or Guarded<S>.

The only operation that is “caused by” the ***dcbtst*** instruction is the providing of the hint. The actions (if any) taken by the processor in response to the hint are not considered to be “caused by” or “associated with” the ***dcbtst*** instruction (e.g., ***dcbtst*** is considered not to cause any data accesses). No means are provided by which software can synchronize these actions with the execution of the instruction stream. For example, these actions are not ordered by memory barriers.

The ***dcbtst*** instruction may complete before the operation it causes has been performed.

The nature of the hint depends, in part, on the value of the TH field, as specified at the beginning of this section. If TH≠0b01010 and TH≠0b01011, this instruction is treated as a *Store* (see Section 4.3), except that the system data storage error handler is not invoked, reference recording<S> need not be done, and change recording<S> is not done.

Special Registers Altered:

None

Extended Mnemonics:

Extended mnemonics are provided for the *Data Cache Block Touch for Store* instruction so that it can be coded with the TH value as the last operand for all categories, and so that the transient hint can be specified without coding the TH field explicitly.

Extended:	Equivalent to:
dcbtstct RA, RB, TH	dcbtst for TH values of 0b00000 or 0b00000 - 0b00111; other TH values are invalid.
dcbtstds RA, RB, TH	dcbtst for TH values of 0b00000 or 0b01000 - 0b01111; other TH values are invalid.
dcbtstt RA, RB	dcbtst for TH value of 0b10000.

Programming Note

See the Programming Notes at the beginning of this section.

Data Cache Block set to Zero **X-form**

dcbz RA, RB

31	///	RA	RB	1014	/
0	6	11	16	21	31

```

if RA = 0 then b ← 0
else            b ← (RA)
EA ← b + (RB)
n ← block size (bytes)
m ← log2(n)
ea ← EA0:63-m || m0
MEM(ea, n) ← 0x00

```

Let the effective address (EA) be the sum (RA10)+(RB).

All bytes in the block containing the byte addressed by EA are set to zero.

This instruction is treated as a Store (see Section 4.3).

Special Registers Altered:

None

Programming Note

dcbz does not cause the block to exist in the data cache if the block is in storage that is Caching Inhibited.

For storage that is neither Write Through Required nor Caching Inhibited, **dcbz** provides an efficient means of setting blocks of storage to zero. It can be used to initialize large areas of such storage, in a manner that is likely to consume less memory bandwidth than an equivalent sequence of *Store* instructions.

For storage that is either Write Through Required or Caching Inhibited, **dcbz** is likely to take significantly longer to execute than an equivalent sequence of *Store* instructions. For example, on some implementations dcbz for such storage may cause the system alignment error handler to be invoked; on such implementations the system alignment error handler sets the specified block to zero using *Store* instructions.

See Section 5.9.1 of Book III-S and Section 6.11.1 of Book III-E for additional information about **dcbz**.

Data Cache Block Store**X-form**

dcbst RA, RB

0	31	6	///	11	RA	16	RB	21	54	31
---	----	---	-----	----	----	----	----	----	----	----

Let the effective address (EA) be the sum (RAI0)+(RB).

If the block containing the byte addressed by EA is in storage that is Memory Coherence Required and a block containing the byte addressed by EA is in the data cache of any processor and any locations in the block are considered to be modified there, those locations are written to main storage, additional locations in the block may be written to main storage, and the block ceases to be considered to be modified in that data cache.

If the block containing the byte addressed by EA is in storage that is not Memory Coherence Required and the block is in the data cache of this processor and any locations in the block are considered to be modified there, those locations are written to main storage, additional locations in the block may be written to main storage, and the block ceases to be considered to be modified in that data cache.

The function of this instruction is independent of whether the block containing the byte addressed by EA is in storage that is Write Through Required or Caching Inhibited.

This instruction is treated as a *Load* (see Section 4.3), except that reference and change recording<S> need not be done, and it is treated as a *Write* with respect to debug events.

Special Registers Altered:

None

Data Cache Block Flush**X-form**

dcbf RA, RB, L

0	31	6	///	9	L	11	RA	16	RB	21	86	31
---	----	---	-----	---	---	----	----	----	----	----	----	----

Let the effective address (EA) be the sum (RAI0)+(RB).

L=0

If the block containing the byte addressed by EA is in storage that is Memory Coherence Required and a block containing the byte addressed by EA is in the data cache of any processor and any locations in the block are considered to be modified there, those locations are written to main storage and additional locations in the block may be written to main storage. The block is invalidated in the data caches of all processors.

If the block containing the byte addressed by EA is in storage that is not Memory Coherence Required and the block is in the data cache of this processor and any locations in the block are considered to be modified there, those locations are written to main storage and additional locations in the block may be written to main storage. The block is invalidated in the data cache of this processor.

L=1 (“dcbf local”) [Category: Server]

The L=1 form of the **dcbf** instruction permits a program to limit the scope of the “flush” operation to the data cache of this processor. If the block containing the byte addressed by EA is in the data cache of this processor, it is removed from this cache. The coherence of the block is maintained to the extent required by the Memory Coherence Required storage attribute.

L = 3 (“dcbf local primary”) [Category: Server]

The L=3 form of the **dcbf** instruction permits a program to limit the scope of the “flush” operation to the primary data cache of this processor. If the block containing the byte addressed by EA is in the primary data cache of this processor, it is removed from this cache. The coherence of the block is maintained to the extent required by the Memory Coherence Required storage attribute.

For the L operand, the value 2 is reserved. The results of executing a **dcbf** instruction with L=2 are boundedly undefined.

The function of this instruction is independent of whether the block containing the byte addressed by EA is in storage that is Write Through Required or Caching Inhibited.

This instruction is treated as a *Load* (see Section 4.3), except that reference and change recording<S> need

not be done, and it is treated as a *Write* with respect to debug events.

Special Registers Altered:

None

Extended Mnemonics:

Extended mnemonics are provided for the *Data Cache Block Flush* instruction so that it can be coded with the L value as part of the mnemonic rather than as a numeric operand. These are shown as examples with the instruction. See Appendix A. “Assembler Extended Mnemonics” on page 717. The extended mnemonics are shown below.

Extended:	Equivalent to:
dcbf RA, RB	dcbf RA, RB, 0
dcbfl RA, RB<S>	dcbf RA, RB, 1
dcbflp RA, RB<S>	dcbf RA, RB, 3

Except in the *dcbf* instruction description in this section, references to “*dcbf*” in Books I-III imply L=0 unless otherwise stated or obvious from context; “*dcbfl*<S>” is used for L=1 and “*dcbflp*<S>” is used for L=3.

Programming Note

dcbf serves as both a basic and an extended mnemonic. The Assembler will recognize a *dcbf* mnemonic with three operands as the basic form, and a *dcbf* mnemonic with two operands as the extended form. In the extended form the L operand is omitted and assumed to be 0.

Programming Note [Category: Server]

dcbf with L=1 can be used to provide a hint that a block in this processor’s data cache will not be reused soon.

dcbf with L=3 can be used to flush a block from the processor’s primary data cache but reduce the latency of a subsequent access. For example, the block may be evicted from the primary data cache but a copy retained in a lower level of the cache hierarchy.

Programs which manage coherence in software must use *dcbf* with L=0.

The treatment of these instructions is independent of whether other Vector instructions are available (i.e., is independent of the contents of MSR_{VEC}<S> (see Book III-S) or MSR_{SPV} (see Book III-E).

Programming Note

These instructions merely provided hints, and thus were permitted to be treated as no-ops even on processors that implemented them.

The treatment of these instructions is independent of whether other Vector instructions are available because, on processors that implemented the instructions, the instructions were available even when other Vector instructions were not.

The extended mnemonics for these instructions were *dstt*, *dsttt*, and *dssall*.

4.3.2.1 Obsolete Data Cache Instructions [Category: Vector.Phased-Out]

The *Data Stream Touch* (*dst*), *Data Stream Touch for Store* (*dstst*), and *Data Stream Stop* (*dss*) instructions (primary opcode 31, extended opcodes 342, 374, and 822 respectively), which were proposed for addition to the Power ISA and were implemented by some processors, must be treated as no-ops (rather than as illegal instructions).

4.4 Synchronization Instructions

The synchronization instructions are used to ensure that certain instructions have completed before other

instructions are initiated, or to control storage access ordering, or to support debug operations.

4.4.1 Instruction Synchronize Instruction

Instruction Synchronize **XL-form**

isync

	19	///	///	///	150	/
0	6	11	16	21	31	31

Executing an *isync* instruction ensures that all instructions preceding the *isync* instruction have completed before the *isync* instruction completes, and that no subsequent instructions are initiated until after the *isync* instruction completes. It also ensures that all instruction cache block invalidations caused by *icbi* instructions preceding the *isync* instruction have been performed with respect to the processor executing the *isync* instruction, and then causes any prefetched instructions to be discarded.

Except as described in the preceding sentence, the *isync* instruction may complete before storage accesses associated with instructions preceding the *isync* instruction have been performed.

This instruction is context synchronizing (see Book III).

Special Registers Altered:

None

4.4.2 Load and Reserve and Store Conditional Instructions

The *Load And Reserve* and *Store Conditional* instructions can be used to construct a sequence of instructions that appears to perform an atomic update operation on an aligned storage location. See Section 1.7.3, “Atomic Update” for additional information about these instructions.

The *Load And Reserve* and *Store Conditional* instructions are fixed-point *Storage Access* instructions; see Section 3.3.1, “Fixed-Point Storage Access Instructions”, in Book I.

The storage location specified by the *Load And Reserve* and *Store Conditional* instructions must be in storage that is Memory Coherence Required if the location may be modified by another processor or mechanism. If the specified location is in storage that is Write Through Required or Caching Inhibited, the system data storage error handler or the system alignment error handler is invoked for the Server environment and may be invoked for the Embedded environment.

The *Load and Reserve* instructions include an Exclusive Access hint (EH), which can be used to indicate that the instruction sequence being executed is implementing one of two types of algorithms:

Atomic Update (EH=0)

This hint indicates that the program is using a fetch and operate (e.g., fetch and add) or some similar algorithm and that all programs accessing the shared variable are likely to use a similar operation to access the shared variable for some time.

Exclusive Access (EH=1)

This hint indicates that the program is attempting to acquire a lock and if it succeeds, will perform another store to the lock variable (releasing the lock) before another program attempts to modify the lock variable.

Programming Note

The Memory Coherence Required attribute on other processors and mechanisms ensures that their stores to the reservation granule will cause the reservation created by the *Load And Reserve* instruction to be lost.

Programming Note

Because the *Load And Reserve* and *Store Conditional* instructions have implementation dependencies (e.g., the granularity at which reservations are managed), they must be used with care. The operating system should provide system library programs that use these instructions to implement the high-level synchronization functions (Test and Set, Compare and Swap, locking, etc.; see Appendix B) that are needed by application programs. Application programs should use these library programs, rather than use the *Load And Reserve* and *Store Conditional* instructions directly.

Programming Note

EH = 1 should be used when the program is obtaining a lock variable which it will subsequently release before another program attempts to perform a store to it. When contention for a lock is significant, using this hint may reduce the number of times a cache block is transferred between processor caches.

EH = 0 should be used when all accesses to a mutex variable are performed using an instruction sequence with *Load and Reserve* followed by *Store Conditional* (e.g., emulating atomic update primitives such as “Fetch and Add;” see Appendix B). The processor may use this hint to optimize the cache to cache transfer of the block containing the mutex variable, thus reducing the latency of performing an operation such as ‘Fetch and Add’.

Programming Note

Either value of the EH field is appropriate for a *Load and Reserve* instruction that is intended to establish a reservation for a subsequent *waitrrsv* and not a subsequent *Store Conditional* instruction.

Programming Note

Warning: On some processors that comply with versions of the architecture that precede Version 2.00, executing a *Load And Reserve* instruction in which EH = 1 will cause the illegal instruction error handler to be invoked.

**Load Byte And Reserve Indexed X-form
[Category: Phased-In]**

lbarx RT,RA,EB,EH

31	RT	RA	RB	52	EH
0	6	11	16	21	31

```
if RA = 0 then b ← 0
else          b ← (RA)
EA ← b +(RB)
```

```
RESERVE ← 1
RESERVE_LENGTH ← 1
RESERVE_ADDR ← real_addr(EA)
RT ← 560 || MEM(EA, 1)
```

Let the effective address (EA) be the sum (RAI0)+(RB). The byte in storage addressed by EA is loaded into RT_{56:63}. RT_{0:55} are set to 0.

This instruction creates a reservation for use by a **stbcx**. instruction. A real address computed from the EA as described in Section 1.7.3.1 is associated with the reservation, and replaces any address previously associated with the reservation. A length of 1 byte is associated with the reservation, and replaces any length previously associated with the reservation.

The value of EH provides a hint as to whether the program will perform a subsequent store to the byte in storage addressed by EA before some other processor attempts to modify it.

- 0 Other programs might attempt to modify the byte in storage addressed by EA regardless of the result of the corresponding **stbcx**. instruction.
- 1 Other programs will not attempt to modify the byte in storage addressed by EA until the program that has acquired the lock performs a subsequent store releasing the lock.

Special Registers Altered:

None

Programming Note

lbarx serves as both a basic and an extended mnemonic. The Assembler will recognize a **lbarx** mnemonic with four operands as the basic form, and a **lbarx** mnemonic with three operands as the extended form. In the extended form the EH operand is omitted and assumed to be 0.

Load Halfword And Reserve Indexed X-form [Category: Phased-In]

lharx RT,RA,EB,EH

31	RT	RA	RB	116	EH
0	6	11	16	21	31

```

if RA = 0 then b ← 0
else          b ← (RA)
EA ← b +(RB)
RESERVE ← 1
RESERVE_LENGTH ← 2
RESERVE_ADDR ← real_addr(EA)
RT ← 480 || MEM(EA, 2)

```

Let the effective address (EA) be the sum (RAI0)+(RB). The halfword in storage addressed by EA is loaded into RT_{48:63}. RT_{0:47} are set to 0.

This instruction creates a reservation for use by a **sthcx** instruction. A real address computed from the EA as described in Section 1.7.3.1 is associated with the reservation, and replaces any address previously associated with the reservation. A length of 2 bytes is associated with the reservation, and replaces any length previously associated with the reservation.

The value of EH provides a hint as to whether the program will perform a subsequent store to the halfword in storage addressed by EA before some other processor attempts to modify it.

- 0 Other programs might attempt to modify the halfword in storage addressed by EA regardless of the result of the corresponding **sthcx** instruction.
- 1 Other programs will not attempt to modify the halfword in storage addressed by EA until the program that has acquired the lock performs a subsequent store releasing the lock.

EA must be a multiple of 2. If it is not, either the system alignment error handler is invoked or the results are boundedly undefined.

Special Registers Altered:

None

Programming Note

lharx serves as both a basic and an extended mnemonic. The Assembler will recognize a **lharx** mnemonic with four operands as the basic form, and a **lharx** mnemonic with three operands as the extended form. In the extended form the EH operand is omitted and assumed to be 0.

Load Word And Reserve Indexed X-form

lwarx RT,RA,EB,EH

31	RT	RA	RB	20	EH
0	6	11	16	21	31

```

if RA = 0 then b ← 0
else          b ← (RA)
EA ← b +(RB)
RESERVE ← 1
RESERVE_LENGTH ← 4
RESERVE_ADDR ← real_addr(EA)
RT ← 320 || MEM(EA, 4)

```

Let the effective address (EA) be the sum (RAI0)+(RB). The word in storage addressed by EA is loaded into RT_{32:63}. RT_{0:31} are set to 0.

This instruction creates a reservation for use by a **stwcx** instruction. A real address computed from the EA as described in Section 1.7.3.1 is associated with the reservation, and replaces any address previously associated with the reservation. A length of 4 bytes is associated with the reservation, and replaces any length previously associated with the reservation.

The value of EH provides a hint as to whether the program will perform a subsequent store to the word in storage addressed by EA before some other processor attempts to modify it.

- 0 Other programs might attempt to modify the word in storage addressed by EA regardless of the result of the corresponding **stwcx** instruction.
- 1 Other programs will not attempt to modify the word in storage addressed by EA until the program that has acquired the lock performs a subsequent store releasing the lock.

EA must be a multiple of 4. If it is not, either the system alignment error handler is invoked or the results are boundedly undefined.

Special Registers Altered:

None

Programming Note

lwarx serves as both a basic and an extended mnemonic. The Assembler will recognize a **lwarx** mnemonic with four operands as the basic form, and a **lwarx** mnemonic with three operands as the extended form. In the extended form the EH operand is omitted and assumed to be 0.

Store Byte Conditional Indexed X-form
[Category: Phased-In]

If a reservation exists and the length associated with the reservation is not 4 bytes, it is undefined whether (RS)_{32:63} are stored into the word in storage addressed by EA.

If a reservation does not exist, no store is performed.

CR Field 0 is set as follows. n is a 1-bit value that indicates whether the store was performed, except that if, per the preceding description, it is undefined whether the store is performed, the value of n is undefined (and need not reflect whether the store was performed).

$$CR0_{LT\ GT\ EQ\ SO} = 0b00 \parallel n \parallel XER_{SO}$$

The reservation is cleared.

EA must be a multiple of 4. If it is not, either the system alignment error handler is invoked or the results are boundedly undefined.

Special Registers Altered:

CR0

4.4.2.1 64-Bit Load and Reserve and Store Conditional Instructions [Category: 64-Bit]

Load Doubleword And Reserve Indexed X-form

ldarx RT,RA,RB,EH

```

if RA = 0 then b ← 0
else            b ← (RA)
EA ← b + (RB)
RESERVE ← 1
RESERVE_LENGTH ← 8
RESERVE_ADDR ← real_addr(EA)
RT ← MEM(EA, 8)

```

Let the effective address (EA) be the sum (RA|0)+(RB). The doubleword in storage addressed by EA is loaded into RT.

This instruction creates a reservation for use by a **stdcx.** instruction. A real address computed from the EA as described in Section 1.7.3.1 is associated with the reservation, and replaces any address previously associated with the reservation. A length of 8 bytes is associated with the reservation, and replaces any length previously associated with the reservation.

The value of EH provides a hint as to whether the program will perform a subsequent store to the doubleword in storage addressed by EA before some other processor attempts to modify it.

- 0 Other programs might attempt to modify the doubleword in storage addressed by EA regardless of the result of the corresponding **stdcx.** instruction.
- 1 Other programs will not attempt to modify the doubleword in storage addressed by EA until the program that has acquired the lock performs a subsequent store releasing the lock.

EA must be a multiple of 8. If it is not, either the system alignment error handler is invoked or the results are boundedly undefined.

Special Registers Altered:

None

Programming Note

ldarx serves as both a basic and an extended mnemonic. The Assembler will recognize a **ldarx** mnemonic with four operands as the basic form, and a **ldarx** mnemonic with three operands as the extended form. In the extended form the EH operand is omitted and assumed to be 0.

Store Doubleword Conditional Indexed X-form

stdcx. RS,RA,RB

```

if RA = 0 then b ← 0
else            b ← (RA)
EA ← b + (RB)
if RESERVE then
  if RESERVE_LENGTH = 8 then
    if RESERVE_ADDR = real_addr(EA) then
      MEM(EA, 8) ← (RS)
      undefined_case ← 0
      store_performed ← 1
    else
      if SCPM category supported then
        z ← smallest real page size supported by
            implementation
        if RESERVE_ADDR + z = real_addr(EA) + z then
          undefined_case ← 1
        else
          undefined_case ← 0
          store_performed ← 0
      else
        undefined_case ← 1
    else
      undefined_case ← 1
  else
    undefined_case ← 0
    store_performed ← 0
if undefined_case then
  u1 ← undefined 1-bit value
  if u1 then
    MEM(EA, 8) ← (RS)
  u2 ← undefined 1-bit value
  CR0 ← 0b00 || u2 || XERSO
else
  CR0 ← 0b00 || store_performed || XERSO
RESERVE ← 0

```

Let the effective address (EA) be the sum (RA|0)+(RB).

If a reservation exists, the length associated with the reservation is 8 bytes, and the real storage location specified by the **stdcx.** is the same as the real storage location specified by the **ldarx** instruction that established the reservation, (RS) is stored into the doubleword in storage addressed by EA.

If a reservation exists, the length associated with the reservation is 8 bytes, and the real storage location specified by the **stdcx.** is not the same as the real storage location specified by the **ldarx** instruction that established the reservation, the following applies.

- If the Store Conditional Page Mobility category is supported, the following applies. Let z denote a naturally aligned block of real storage whose size

is the smallest real page size supported by the implementation. If the real storage location specified by the *stdcx* is in the same *z* as the real storage location specified by the *ldarx* instruction that established the reservation, it is undefined whether (RS) is stored into the doubleword in storage addressed by EA. Otherwise, no store is performed.

- If the Store Conditional Page Mobility category is not supported, it is undefined whether (RS) is stored into the doubleword in storage addressed by EA.

If a reservation exists and the length associated with the reservation is not 8 bytes, it is undefined whether (RS) is stored into the doubleword in storage addressed by EA.

If a reservation does not exist, no store is performed.

CR Field 0 is set as follows. *n* is a 1-bit value that indicates whether the store was performed, except that if, per the preceding description, it is undefined whether the store is performed, the value of *n* is undefined (and need not reflect whether the store was performed).

$$CR0_{LT\ GT\ EQ\ SO} = 0b00\ ||\ n\ ||\ XER_{SO}$$

The reservation is cleared.

EA must be a multiple of 8. If it is not, either the system alignment error handler is invoked or the results are boundedly undefined.

Special Registers Altered:

CR0

4.4.3 Memory Barrier Instructions

The *Memory Barrier* instructions can be used to control the order in which storage accesses are performed. Additional information about these instructions and about related aspects of storage management can be found in Book III.

Extended mnemonics for Synchronize

Extended mnemonics are provided for the *Synchronize* instruction so that it can be supported by assemblers that recognize only the *msync*<E> mnemonic and so that it can be coded with the L value as part of the mnemonic rather than as a numeric operand. These are shown as examples with the instruction. See Appendix A. “Assembler Extended Mnemonics” on page 717. The only reason for the *msync*<E> mnemonic is compatibility with Book E assembler code.

Synchronize

X-form

sync L

0	31	///	L	///	///	598	/
	6	9	11	16	21	31	

The *sync* instruction creates a memory barrier (see Section 1.7.1). The set of storage accesses that is ordered by the memory barrier depends on the value of the L field.

L=0 (“heavyweight sync”)

The memory barrier provides an ordering function for the storage accesses associated with all instructions that are executed by the processor executing the *sync* instruction. The applicable pairs are all pairs a_i, b_j in which b_j is a data access, except that if a_i is the storage access caused by an *icbi* instruction then b_j may be performed with respect to the processor executing the *sync* instruction before a_i is performed with respect to that processor.

L=1 (“lightweight sync”)

The memory barrier provides an ordering function for the storage accesses caused by *Load*, *Store*, and *dcbz* instructions that are executed by the processor executing the *sync* instruction and for which the specified storage location is in storage that is Memory Coherence Required and is neither Write Through Required nor Caching Inhibited. The applicable pairs are all pairs a_i, b_j of such accesses except those in which a_i is an access caused by a *Store* or *dcbz* instruction and b_j is an access caused by a *Load* instruction.

L=2<S>

The set of storage accesses that is ordered by the memory barrier is described in Section 5.9.2 of Book III-S, as are additional properties of the *sync* instruction with L=2.

The ordering done by the memory barrier is cumulative.

If L=0 (or L=2<S>), the *sync* instruction has the following additional properties.

- Executing the *sync* instruction ensures that all instructions preceding the *sync* instruction have completed before the *sync* instruction completes, and that no subsequent instructions are initiated until after the *sync* instruction completes.
- The *sync* instruction is execution synchronizing (see Book III). However, address translation and reference and change recording<S> (see Book III) associated with subsequent instructions may be performed before the *sync* instruction completes.
- The memory barrier provides the additional ordering function such that if a given instruction that is the result of a store in set B is executed, all applicable storage accesses in set A have been performed with respect to the processor executing the instruction to the extent required by the associated memory coherence properties. The single exception is that any storage access in set A that is caused by an *icbi* instruction executed by the processor executing the *sync* instruction (P1) may not have been performed with respect to P1 (see the description of the *icbi* instruction on page 680).

The cumulative properties of the barrier apply to the execution of the given instruction as they would to a load that returned a value that was the result of a store in set B.

- The *sync* instruction provides an ordering function for the operations caused by the stream variants of the *dcbt* and *dcbtst* instructions (i.e. the providing of hints).

The value L=3 is reserved.

The *sync* instruction may complete before storage accesses associated with instructions preceding the *sync* instruction have been performed. The *sync* instruction may complete before operations caused by *dcbt* and *dcbtst* instructions preceding the *sync* instruction have been performed.

See Section 6.11.3 of Book III-E for additional information related to **sync** with L=0 for the Embedded environment.

Special Registers Altered:

None

Extended Mnemonics:

Extended mnemonics for *Synchronize*:

Extended:	Equivalent to:
sync	sync 0
msync<E>	sync 0
lwsync	sync 1
ptesync<S>	sync 2

Except in the **sync** instruction description in this section, references to “**sync**” in Books I-III imply L=0 unless otherwise stated or obvious from context; the appropriate extended mnemonics are used when other L values are intended.

Programming Note

Section 1.8 contains a detailed description of how to modify instructions such that a well-defined result is obtained.

Programming Note

sync serves as both a basic and an extended mnemonic. The Assembler will recognize a **sync** mnemonic with one operand as the basic form, and a **sync** mnemonic with no operand as the extended form. In the extended form the L operand is omitted and assumed to be 0.

Programming Note

The **sync** instruction can be used to ensure that all stores into a data structure, caused by *Store* instructions executed in a “critical section” of a program, will be performed with respect to another processor before the store that releases the lock is performed with respect to that processor; see Section B.2, “Lock Acquisition and Release, and Related Techniques” on page 721.

The memory barrier created by a **sync** instruction with L=0 or L=1 does not order implicit storage accesses. The memory barrier created by a **sync** instruction with any L value does not order instruction fetches.

(The memory barrier created by a **sync** instruction with L=0 – or L=2<S>; see Book III – appears to order instruction fetches for instructions preceding the **sync** instruction with respect to data accesses caused by instructions following the **sync** instruction. However, this ordering is a consequence of the first “additional property” of **sync** with L=0, not a property of the memory barrier.)

In order to obtain the best performance across the widest range of implementations, the programmer should use the **sync** instruction with L=1, or the **eieio**<S> or **mbar**<E> instruction, if any of these is sufficient for his needs; otherwise he should use **sync** with L=0. **sync** with L=2<S> should not be used by application programs.

Programming Note

The functions provided by **sync** with L=1 are a strict subset of those provided by **sync** with L=0. (The functions provided by **sync** with L=2<S> are a strict superset of those provided by **sync** with L=0; see Book III.)

Enforce In-order Execution of I/O X-form

eieio
[Category: Server]

31	///	///	///	854	/
0	6	11	16	21	31

The *eieio* instruction creates a memory barrier (see Section 1.7.1, “Storage Access Ordering”), which provides an ordering function for the storage accesses caused by *Load*, *Store*, *dcbz*, *eciwx*, and *ecowx* instructions executed by the processor executing the *eieio* instruction. These storage accesses are divided into the two sets listed below. The storage access caused by an *eciwx* instruction is ordered as a load, and the storage access caused by a *dcbz* or *ecowx* instruction is ordered as a store.

1. Loads and stores to storage that is both Caching Inhibited and Guarded, and stores to main storage caused by stores to storage that is Write Through Required.

The applicable pairs are all pairs a_i, b_j of such accesses.

2. Stores to storage that is Memory Coherence Required and is neither Write Through Required nor Caching Inhibited.

The applicable pairs are all pairs a_i, b_j of such accesses.

The operations caused by the stream variants of the *dcbt* and *dcbtst* instructions (i.e. the providing of hints) are ordered by *eieio* as a third set of operations, and the operations caused by *tlbie<S>* and *tlbsync* instructions (see Book III-S) are ordered by *eieio* as a fourth set of operations.

Each of the four sets of storage accesses or operations is ordered independently of the other three sets. The ordering done by *eieio*'s memory barrier for the second set is cumulative; the ordering done by *eieio*'s memory barrier for the other three sets is not cumulative.

The *eieio* instruction may complete before storage accesses associated with instructions preceding the *eieio* instruction have been performed. The *eieio* instruction may complete before operations caused by *dcbt* and *dcbtst* instructions preceding the *eieio* instruction have been performed

Special Registers Altered:

None

Memory Barrier**X-form**

mbar MO
[Category: Embedded]

31	MO	///	///	854	/
0	6	11	16	21	31

When MO=0, the *mbar* instruction creates a cumulative memory barrier (see Section 1.7.1, “Storage Access Ordering”), which provides an ordering function for the storage accesses executed by the processor executing the *mbar* instruction.

When MO≠0, an implementation may support the *mbar* instruction ordering a particular subset of storage accesses. An implementation may also support multiple, non-zero values of MO that each specify a different subset of storage accesses that are ordered by the *mbar* instruction. Which subsets of storage accesses that are ordered and which values of MO that specify these subsets is implementation-dependent.

The *mbar* instruction may complete before storage accesses associated with instructions preceding the *mbar* instruction have been performed. The *mbar* instruction may complete before operations caused by *dcbt* and *dcbtst* instructions preceding the sync instruction have been performed.

Special Registers Altered:

None

Programming Note

The *eieio<S>* and *mbar<E>* instructions are intended for use in doing memory-mapped I/O). Because loads, and separately stores, to storage that is both Caching Inhibited and Guarded are performed in program order (see Section 1.7.1, “Storage Access Ordering” on page 660), *eieio<S>* or *mbar<E>* is needed for such storage only when loads must be ordered with respect to stores.

For the *eieio<S>* instruction, accesses in set 1, a_i and b_j need not be the same kind of access or be to storage having the same storage control attributes. For example, a_i can be a load to Caching Inhibited, Guarded storage, and b_j a store to Write Through Required storage.

If stronger ordering is desired than that provided by *eieio<S>* or *mbar<E>*, the *sync* instruction must be used, with the appropriate value in the L field.

Programming Note

The functions provided by *eieio*<S> and *mbar*<E> are a strict subset of those provided by *sync* with L=0. The functions provided by *eieio*<S> for its second set are a strict subset of those provided by *sync* with L=1.

Since *eieio*<S> and *mbar*<E> share the same opcode, software designed for both server and embedded environments must assume that only the *eieio*<S> functionality applies since the functions provided by *eieio* are a subset of those provided by *mbar* with MO=0.

4.4.4 Wait Instruction**Wait****X-form**

wait WC

[Category: Wait.Phased-In]

0	31	///	WC	///	///	62	/
	6	9	11	16	21	31	

wait

[Category: Wait.Phased-Out]

0	31	///	///	///	62	/
	6	11	16	21	31	

The **wait** instruction allows instruction fetching and execution to be suspended under certain conditions, depending on the value of the WC field. A **wait** instruction without the WC field is treated as a **wait** instruction with WC=0.

The defined values for WC are as follows.

- 0b00 Resume instruction fetching and execution when an interrupt occurs.
- 0b01 Resume instruction fetching and execution when an interrupt occurs or when a reservation made by the processor does not exist (see Section 1.7.3). It is implementation-dependent whether this WC value is supported or **wait** with this WC value is treated as a no-op.
- 0b10 Resume instruction fetching and execution when an interrupt occurs or when an implementation-specific condition exists. It is implementation-dependent whether this WC value is supported or is treated as reserved.
- 0b11 This WC value is treated as a no-op.

If WC=0, or if WC=1 and a reservation made by the processor exists when the wait instruction is executed, or if WC=2 and the associated implementation-specific condition does not exist when the **wait** instruction is executed, the following applies.

- Instruction fetching and execution is suspended.
- Once the **wait** instruction has completed, the NIA will point to the next sequential instruction.
- Instruction fetching and execution resumes when any of the following conditions are met.
 - An interrupt occurs.
 - WC=1 and a reservation made by the processor does not exist.
 - WC=2 and the associated implementation-specific condition exists.

When the **wait** instruction is executed, if WC=1 and a reservation made by the processor does not exist, or if WC=2 and the associated implementation-specific condition exists, the instruction is treated as a no-op.

Programming Note

On implementations which do not support the wait instruction with WC=0b10, the behavior for non-support (treated as reserved) differs from the non-support of the other non-zero WC values (treated as no-ops). The possibility of boundedly undefined behavior such as causing the system illegal instruction error handler to be invoked is meant to discourage the use of WC=0b10 in programs that are intended to be portable.

Only programs that are implementation-aware should use WC=0b10.

Engineering Note

Causing the system illegal instruction error handler to be invoked if an attempt is made to execute **wait** with WC=0b10 on an implementation that does not support that form of **wait** facilitates the debugging of software.

Programming Note

Execution of a **wait** instruction indicates that no further instruction fetching will occur until the condition(s) associated with the WC field value for the instruction take place. The main purpose of the **wait** instruction is to enable power savings. **wait** frees computational resources which might be allocated to another program or converted into power savings.

If an interrupt causes resumption of instruction execution, the interrupt handler will return to the instruction after the **wait**.

Engineering Note

In previous versions of the architecture the **wait** instruction was context synchronizing.

Special Registers Altered:

None

Extended Mnemonics:

Examples of extended mnemonics for *Wait*:

Extended:	Equivalent to:
wait	wait 0
waitrsv	wait 1
waitimpl	wait 2

Programming Note

The **wait** instruction with WC=0b00 can be used in verification test cases to signal the end of a test case. The encoding for the instruction is the same in both Big-Endian and Little-Endian modes.

Programming Note

The **wait** instruction may be useful as the primary instruction of an "idle process" or the completion of processing for a cooperative processor. However, overall system performance may be better served if the **wait** instruction is used by applications only for idle times that are expected to be short.

Programming Note

The **wait** instruction is not execution synchronizing and does not cause a memory barrier. **waitrsv** behavior relative to a preceding *Load and Reserve* instruction or *Store Conditional* instruction has a data dependency on the reservation. When execution proceeds past **waitrsv** as the result of another processor storing to the reservation granule, a subsequent load from the same storage location may return stale data. It is also possible that execution could proceed past the **waitrsv** for other reasons such as the occurrence of an interrupt. There are no architecturally defined means to determine what terminated the **wait**. Moreover, even if software were to attempt to determine what caused the **wait** to terminate, by the time the check occurred, both causes (interrupt and storage modification) might be true. Software must be designed to deal with the various causes of **wait** termination. In general, if the program that performed **wait** does not see the new value of the storage location for which the reservation was held, it should re-establish the reservation by repeating the *Load and Reserve* instruction, and then perform another **waitrsv**.

The following code waits for a device to update a memory location and assumes that r3 contains the address of the word to be updated. This assumes that software has already set this word to zero and is waiting for the device to update the word to a non-zero value.

```
loop:
    lwarx  r4,0,r3 # load and reserve
    cmpwi  r4,0   # exit if nonzero
    bne-   exit
    waitrsv      # wait for reservation loss
    b       loop
exit: ...
```

The **b** instruction results in re-execution of the **waitrsv** if instruction execution had resumed for some reason other than loss of the reservation made by the processor. This branch instruction is also necessary because the reservation might have been lost for reasons other than the device updating the memory location addressed by r3. Also, even if the device updated this memory location, the **lwarx** and **waitrsv** instructions may need to be re-executed until the **lwarx** returns the current data.

Programming Note

A **wait** instruction without the WC field is treated as a **wait** instruction with WC=0b00 because older processors that comply with Power ISA 2.06 do not support the WC field.

Chapter 5. Time Base

5.1 Time Base Overview.	707	5.3 Alternate Time Base [Category: Alternate Time Base]	710
5.2 Time Base	707		
5.2.1 Time Base Instructions	708		

5.1 Time Base Overview

The time base facilities include a Time Base and an Alternate Time Base which is category: Alternate Time Base. The Alternate Time Base is analogous to the Time Base except that it may count at a different frequency and is not writable.

5.2 Time Base

The Time Base (TB) is a 64-bit register (see Figure 5) containing a 64-bit unsigned integer that is incremented periodically as described below.

Field	Description
TBU	Upper 32 bits of Time Base
TBL	Lower 32 bits of Time Base

Figure 5. Time Base

The Time Base bits 0:59 increment until their value becomes 0xFFFF_FFFF_FFFF_FFFF ($2^{59} - 1$), at the next increment their value becomes 0x000_0000_0000_0000. There is no interrupt or other indication when this occurs.

Time base bits 60:63 may increment at a variable rate. When the value of bit 59 changes, bits 60:63 are set to zero; if bits 60:63 increment to 0xF before the value of bit 59 changes, they remain at 0xF until the value of bit 59 changes.

$$T_{TB} = \frac{2^{64} \times 32}{1\text{GHz}} = 5.90 \times 10^{11} \text{ seconds}$$

which is approximately 18,700 years.

The Power ISA AS does not specify a relationship between the frequency at which the Time Base is

updated and other frequencies, such as the CPU clock or bus clock. The Time Base update frequency is not required to be constant. What *is* required, so that system software can keep time of day and operate interval timers, is one of the following.

- The system provides an (implementation-dependent) interrupt to software whenever the update frequency of the Time Base bits 0:59 changes, and a means to determine what the current update frequency is.
- The update frequency of the Time Base bits 0:59 is under the control of the system software.

Programming Note

If the operating system initializes the Time Base on power-on to some reasonable value and the update frequency of the Time Base is constant, the Time Base can be used as a source of values that increase at a constant rate, such as for time stamps in trace entries.

Even if the update frequency is not constant, values read from the Time Base are monotonically increasing (except when the Time Base wraps from $2^{64}-1$ to 0). If a trace entry is recorded each time the update frequency changes, the sequence of Time Base values can be post-processed to become actual time values.

Successive readings of the Time Base may return identical values.

5.2.1 Time Base Instructions

Move From Time Base **XFX-form**

mftb RT,TBR
[Category: Phased-Out]

31	RT	tbr	371	/
----	----	-----	-----	---

0	6	11	21	31
---	---	----	----	----

This instruction behaves as if it were an *mf spr* instruction; see the *mf spr* instruction description in Section 3.3.15 of Book I.

Special Registers Altered:

None

Extended Mnemonics:

Extended mnemonics for *Move From Time Base*:

Extended:	Equivalent to:
mftb Rx	mftb Rx,268 mf spr Rx,268
mftbu Rx	mftb Rx,269 mf spr Rx,269

Programming Note

New programs should use *mf spr* instead of *mftb* to access the Time Base.

Programming Note

mftb serves as both a basic and an extended mnemonic. The Assembler will recognize an *mftb* mnemonic with two operands as the basic form, and an *mftb* mnemonic with one operand as the extended form. In the extended form the TBR operand is omitted and assumed to be 268 (the value that corresponds to TB).

Programming Note

The *mf spr* instruction can be used to read the Time Base on all processors that comply with Version 2.01 of the architecture or with any subsequent version.

It is believed that the *mf spr* instruction can be used to read the Time Base on most processors that comply with versions of the architecture that precede Version 2.01. Processors for which *mf spr* cannot be used to read the Time Base include the following.

- 601
- POWER3

(601 implements neither the Time Base nor *mftb*, but depends on software using *mftb* to read the Time Base, so that the attempt causes the Illegal Instruction error handler to be invoked and thereby permits the operating system to emulate the Time Base.)

Programming Note

Since the update frequency of the Time Base is implementation-dependent, the algorithm for converting the current value in the Time Base to time of day is also implementation-dependent.

As an example, assume that the Time Base increments at the constant rate of 512 MHz. (Note, however, that programs should allow for the possibility that some implementations may not increment the least-significant 4 bits of the Time Base at a constant rate.) What is wanted is the pair of 32-bit values comprising a POSIX standard clock:¹ the number of whole seconds that have passed since 00:00:00 January 1, 1970, UTC, and the remaining fraction of a second expressed as a number of nanoseconds.

Assume that:

- The value 0 in the Time Base represents the start time of the POSIX clock (if this is not true, a simple 64-bit subtraction will make it so).
- The integer constant *ticks_per_sec* contains the value 512,000,000, which is the number of times the Time Base is updated each second.
- The integer constant *ns_adj* contains the value

$$\frac{1,000,000,000}{512,000,000} \times 2^{32} / 2 = 4194304000$$

which is the number of nanoseconds per tick of the Time Base, multiplied by 2^{32} for use in *mulhwu* (see below), and then divided by 2 in order to fit, as an unsigned integer, into 32 bits.

When the processor is in 64-bit mode, The POSIX clock can be computed with an instruction sequence such as this:

```

mfspr  Ry,268 # Ry = Time Base
lwz    Rx,ticks_per_sec
divdu  Rz,Ry,Rx # Rz = whole seconds
stw    Rz,posix_sec

```

```

mulld  Rz,Rz,Rx # Rz = quotient * divisor
sub    Rz,Ry,Rz # Rz = excess ticks
lwz    Rx,ns_adj
slwi   Rz,Rz,1  # Rz = 2 * excess ticks
mulhwu Rz,Rz,Rx # mul by (ns/tick)/2 * 232
stw    Rz,posix_ns# product[0:31] = excess ns

```

For the Embedded environment when the processor is in 32-bit mode, it is not possible to read the Time Base using a single instruction. Instead, two instructions must be used, one of which reads TBL and the other of which reads TBU. Because of the possibility of a carry from TBL to TBU occurring between the two reads, a sequence such as the following must be used to read the Time Base.

```

loop:
mfspr  Rx,TBU # load from TBU
mfspr  Ry,TB  # load from TB
mfspr  Rz,TBU # load from TBU
cmp    cr0,0,Rx,Rz# check if 'old'='new'
bne    loop  #branch if carry occurred

```

Non-constant update frequency

In a system in which the update frequency of the Time Base may change over time, it is not possible to convert an isolated Time Base value into time of day. Instead, a Time Base value has meaning only with respect to the current update frequency and the time of day that the update frequency was last changed. Each time the update frequency changes, either the system software is notified of the change via an interrupt (see Book III), or the change was instigated by the system software itself. At each such change, the system software must compute the current time of day using the old update frequency, compute a new value of *ticks_per_sec* for the new frequency, and save the time of day, Time Base value, and tick rate. Subsequent calls to compute Time of Day use the current Time Base Value and the saved value.

1. Described in POSIX Draft Standard P1003.4/D12, *Draft Standard for Information Technology -- Portable Operating System Interface (POSIX) -- Part 1: System Application Program Interface (API) - Amendment 1: Real-time Extension [C Language]*. Institute of Electrical and Electronics Engineers, Inc., Feb. 1992.

5.3 Alternate Time Base [Category: Alternate Time Base]

The Alternate Time Base (ATB) is a 64-bit register (see Figure 5) containing a 64-bit unsigned integer that is incremented periodically. The frequency at which the integer is updated is implementation-dependent.

Figure 6. Alternate Time Base

The ATBL register is an aliased name for the ATB.

The Alternate Time Base increments until its value becomes 0xFFFF_FFFF_FFFF_FFFF ($2^{64} - 1$). At the next increment, its value becomes 0x0000_0000_0000_0000. There is no explicit indication (such as an interrupt; see Book III) that this has occurred.

The Alternate Time Base is accessible in both user and supervisor mode. The counter can be read by executing a *mfspr* instruction specifying the ATB (or ATBL) register, but cannot be written. A second SPR register ATBU, is defined that accesses only the upper 32 bits of the counter. Thus the upper 32 bits of the counter may be read into a register by reading the ATBU register.

The effect of entering a power-savings mode or of processor frequency changes on counting in the Alternate Time Base is implementation-dependent.

Chapter 6. Decorated Storage Facility [Category: Decorated Storage]

6.1 Decorated Load Instructions 712
6.2 Decorated Store Instructions 713

6.3 Decorated Notify Instructions 714

The *Decorated Storage* facility provides *Load*, *Store*, and *Notify* operations to storage that have additional semantics other than the reading and writing of data values to the addressed storage locations. A decoration is specified that provides semantic information about how the operation is to be performed. A decorated device is a device that implements an address range of storage, and applies decorations to operations performed on the address range of storage.

A *Decorated Storage* instruction specifies the following attributes:

- The type of access, which is either a *Decorated Load*, *Decorated Store*, or a *Decorated Notify*.
- The EA in register RB, to which the operation is to be performed.
- The decoration in register RA, which further defines what operation should be performed by the decorated device.
- The data itself, either data provided by the processor to the decorated device (in the case of a *Decorated Store*), or the data provided by the decorated device to be consumed by the processor (in the case of a *Decorated Load*). *Decorated Notify* operations do not contain data.

The semantics of any *Decorated Storage* operation that is Caching Inhibited are defined by the decorated device depending on whether it is a *Decorated Load*, *Decorated Store*, or *Decorated Notify*, and the value supplied as a decoration. Such semantics may differ from decorated device to decorated device similar to how devices other than well-behaved memory may treat *Load* and *Store* operations. The semantics of any operation associated with a *Decorated Storage* operation that is not Caching Inhibited are the same as an analogous *Load* or *Store* instruction of the same data size.

The results of a *Decorated Storage* operation that is Caching Inhibited to a device that does not support decorations is boundedly undefined. The results of a *Load* or *Store* operation that is Caching Inhibited to a

decorated device that requires a decoration is boundedly undefined.

For *Decorated Load* operations, a *Load* operation with the specified decoration is performed to the EA and the data provided by the decorated device is placed in the target register.

For *Decorated Store* operations, a *Store* operation using the data specified in the source register with the specified decoration is performed to the EA.

Decorated Load instructions are treated as *Load* instructions for address translation, access control, debug events, storage attributes, alignment, and memory access ordering. *Decorated Store* instructions are treated as *Store* instructions for address translation, access control, debug events, storage attributes, alignment, and memory access ordering. A *Decorated Notify* instruction is treated as a zero byte *Store* for address translation, access control, debug events, storage attributes, alignment, and memory access ordering.

Programming Note

Software should be acutely aware of how transactions to a decorated device that implements Decorated Storage will occur. Not only does this imply knowing the particular decorated device's semantics, but also ensuring that the transactions are appropriately issued by the processor. This includes alignment, speculative accesses, and ordering. In general, Caching Inhibited accesses are required to be Guarded and properly aligned.

6.1 Decorated Load Instructions

Load Byte with Decoration Indexed X-form

lbdx RT,RA,RB

EA ← (RB)
RT ← $^{56}_0$ || MEM_DECORATED(EA, 1, (RA))

Let the effective address (EA) be the contents of RB. The byte in storage addressed by EA is loaded using the decoration supplied by (RA) into RT_{56:63}. RT_{0:55} are set to 0.

Special Registers Altered:
None

Load Halfword with Decoration Indexed X-form

lhdx RT,RA,RB

EA ← (RB)
RT ← $^{48}_0$ || MEM_DECORATED(EA, 2, (RA))

Let the effective address (EA) be the contents of RB. The halfword in storage addressed by EA is loaded using the decoration supplied by (RA) into RT_{48:63}. RT_{0:47} are set to 0.

Special Registers Altered:
None

Load Word with Decoration Indexed X-form

lwdx RT,RA,RB

EA ← (RB)
RT ← $^{32}_0$ || MEM_DECORATED(EA, 4, (RA))

Let the effective address (EA) be the contents of RB. The word in storage addressed by EA is loaded using the decoration supplied by (RA) into RT_{32:63}. RT_{0:31} are set to 0.

Special Registers Altered:
None

Load Doubleword with Decoration Indexed X-form

lddx RT,RA,RB [Co-requisite category: 64-Bit]

EA ← (RB)
RT ← MEM_DECORATED(EA, 8, (RA))

Let the effective address (EA) be the contents of RB. The doubleword in storage addressed by EA is loaded using the decoration supplied by (RA) into RT.

Special Registers Altered:
None

Load Floating Doubleword with Decoration Indexed X-form

lfdx FRT,RA,RB [Co-requisite category: FP]

EA ← (RB)
FRT ← MEM_DECORATED(EA, 8, (RA))

Let the effective address (EA) be the contents of RB. The doubleword in storage addressed by EA is loaded using the decoration supplied by (RA) into FRT.

Special Registers Altered:
None

6.2 Decorated Store Instructions

Store Byte with Decoration Indexed X-form

stbdx RS,RA,RB

$EA \leftarrow (RB)$
 $MEM_DECORATED(EA, 1, (RA)) \leftarrow (RS)_{56:63}$

Let the effective address (EA) be the contents of RB. (RS)_{56:63} are stored to the byte in storage addressed by EA using the decoration supplied by (RA).

Special Registers Altered:
None

Store Halfword with Decoration Indexed X-form

sthdx RS,RA,RB

$EA \leftarrow (RB)$
 $MEM_DECORATED(EA, 2, (RA)) \leftarrow (RS)_{48:63}$

Let the effective address (EA) be the contents of RB. (RS)_{48:63} are stored to the halfword in storage addressed by EA using the decoration supplied by (RA).

Special Registers Altered:
None

Store Word with Decoration Indexed X-form

stwdx RS,RA,RB

$EA \leftarrow (RB)$
 $MEM_DECORATED(EA, 4, (RA)) \leftarrow (RS)_{32:63}$

Let the effective address (EA) be the contents of RB. (RS)_{32:63} are stored to the word in storage addressed by EA using the decoration supplied by (RA).

Special Registers Altered:
None

Store Doubleword with Decoration Indexed X-form

stddx RS,RA,RB [Co-requisite category: 64-Bit]

$EA \leftarrow (RB)$
 $MEM_DECORATED(EA, 8, (RA)) \leftarrow (RS)$

Let the effective address (EA) be the contents of RB. (RS) is stored to the doubleword in storage addressed by EA using the decoration supplied by (RA).

Special Registers Altered:
None

Store Floating Doubleword with Decoration Indexed X-form

stfddx FRS,RA,RB [Co-requisite category: FP]

$EA \leftarrow (RB)$
 $MEM_DECORATED(EA, 8, (RA)) \leftarrow (FRS)$

Let the effective address (EA) be the contents of RB. (FRS) is stored to the doubleword in storage addressed by EA using the decoration supplied by (RA).

Special Registers Altered:
None

6.3 Decorated Notify Instructions

Decorated Storage Notify *X-form*

dsn RA, RB

0	31	6	///	11	RA	16	RB	21	483	31	/
---	----	---	-----	----	----	----	----	----	-----	----	---

EA ← (RB)

MEM_NOTIFY (EA, (RA))

Let the effective address (EA) be the contents of RB.
The decoration supplied by (RA) is sent to the address
in storage specified by EA.

Special Registers Altered:

None

Chapter 7. External Control [Category: External Control]

The External Control category of facilities and instructions permits a program to communicate with a special-purpose device. Two instructions are provided, both of which must be implemented if the facility is provided.

- *External Control In Word Indexed (eciwx)*, which does the following:
 - Computes an effective address (EA) like most X-form instructions
 - Validates the EA as would be done for a load from that address
 - Translates the EA to a real address
 - Transmits the real address to the device
 - Accepts a word of data from the device and places it into a General Purpose Register
- *External Control Out Word Indexed (ecowx)*, which does the following:
 - Computes an effective address (EA) like most X-form instructions
 - Validates the EA as would be done for a store to that address
 - Translates the EA to a real address
 - Transmits the real address and a word of data from a General Purpose Register to the device

Permission to execute these instructions and identification of the target device are controlled by two fields, called the E bit and the RID field respectively. If attempt is made to execute either of these instructions when E=0 the system data storage error handler is invoked. The location of these fields is described in Book III.

The storage access caused by *eciwx* and *ecowx* is performed as though the specified storage location is Caching Inhibited and Guarded, and is neither Write Through Required nor Memory Coherence Required.

Interpretation of the real address transmitted by *eciwx* and *ecowx* and of the 32-bit value transmitted by *ecowx* is up to the target device, and is not specified by the Power ISA. See the System Architecture documentation for a given Power ISA system for details on how the External Control facility can be used with devices on that system.

Example

An example of a device designed to be used with the External Control facility might be a graphics adapter.

The *ecowx* instruction might be used to send the device the translated real address of a buffer containing graphics data, and the word transmitted from the General Purpose Register might be control information that tells the adapter what operation to perform on the data in the buffer. The *eciwx* instruction might be used to load status information from the adapter.

A device designed to be used with the External Control facility may also recognize events that indicate that the address translation being used by the processor has changed. In this case the operating system need not “pin” the area of storage identified by an *eciwx* or *ecowx* instruction (i.e., need not protect it from being paged out).

7.1 External Access Instructions

In the instruction descriptions the statements “this instruction is treated as a *Load*” and “this instruction is

treated as a *Store*” have the same meanings as for the *Cache Management* instructions; see Section 4.3.

External Control In Word Indexed X-form

eciwx RT,RA,RB

31	RT	RA	RB	310	/
0	6	11	16	21	31

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
raddr ← address translation of EA
send load word request for raddr to
      device identified by RID
RT ← 320 || word from device

```

Let the effective address (EA) be the sum (RA)I0)+(RB).

A load word request for the real address corresponding to EA is sent to the device identified by RID, bypassing the cache. The word returned by the device is placed into RT_{32:63}. RT_{0:31} are set to 0.

The E bit must be 1. If it is not, the data storage error handler is invoked.

EA must be a multiple of 4. If it is not, either the system alignment error handler is invoked or the results are boundedly undefined.

This instruction is treated as a *Load*.

See Book III-S for additional information about this instruction.

Special Registers Altered:

None

Programming Note

The *eieio*<S> or *mbar*<E> instruction can be used to ensure that the storage accesses caused by *eciwx* and *ecowx* are performed in program order with respect to other Caching Inhibited and Guarded storage accesses.

External Control Out Word Indexed X-form

ecowx RS,RA,RB

31	RS	RA	RB	438	/
0	6	11	16	21	31

```

if RA = 0 then b ← 0

```

```

else      b ← (RA)
EA ← b + (RB)
raddr ← address translation of EA
send store word request for raddr to
      device identified by RID
send (RS)32:63 to device

```

Let the effective address (EA) be the sum (RA)I0)+(RB).

A store word request for the real address corresponding to EA and the contents of RS_{32:63} are sent to the device identified by RID, bypassing the cache.

The E bit must be 1. If it is not, the data storage error handler is invoked.

EA must be a multiple of 4. If it is not, either the system alignment error handler is invoked or the results are boundedly undefined.

This instruction is treated as a *Store*, except that its storage access is not performed in program order with respect to accesses to other Caching Inhibited and Guarded storage locations unless software explicitly imposes that order.

See Book III-S for additional information about this instruction.

Special Registers Altered:

None

Appendix A. Assembler Extended Mnemonics

In order to make assembler language programs simpler to write and easier to understand, a set of extended mnemonics and symbols is provided for certain instructions. This appendix defines extended mnemonics and

symbols related to instructions defined in Book II. Assemblers should provide the extended mnemonics and symbols listed here, and may provide others.

A.1 Data Cache Block Flush Mnemonics

The L field in the *Data Cache Block Flush* instruction controls the scope of the flush function performed by the instruction. Extended mnemonics are provided that represent the L value in the mnemonic rather than requiring it to be coded as a numeric operand.

Note: *dcbf* serves as both a basic and an extended mnemonic. The Assembler will recognize a *dcbf* mnemonic with three operands as the basic form, and a *dcbf* mnemonic with two operands as the extended form. In the extended form the L operand is omitted and assumed to be 0.

dcbf RA, RB (equivalent to: dcbf RA, RB, 0)
dcbfl<S> RA, RB (equivalent to: dcbfl RA, RB, 1)

A.2 Load and Reserve Mnemonics

The EH field in the *Load and Reserve* instructions provides a hint regarding the type of algorithm implemented by the instruction sequence being executed. Extended mnemonics are provided that allow the EH value to be omitted and assumed to be 0b0.

Note: *lbarx*, *lharx*, *lwarx*, and *ldarx* serve as both basic and extended mnemonics. The Assembler will recognize these mnemonics with four operands as the basic form, and these mnemonics with three operands as the extended form. In the extended form the EH operand is omitted and assumed to be 0.

lbarx RT, RA, RB (equivalent to: lbarx RT, RA, RB, 0)
lharx RT, RA, RB (equivalent to: lharx RT, RA, RB, 0)
lwarx RT, RA, RB (equivalent to: lwarx RT, RA, RB, 0)
ldarx RT, RA, RB (equivalent to: ldarx RT, RA, RB, 0)

A.3 Synchronize Mnemonics

The L field in the *Synchronize* instruction controls the scope of the synchronization function performed by the instruction. Extended mnemonics are provided that represent the L value in the mnemonic rather than requiring it to be coded as a numeric operand. Two extended mnemonics are provided for the L=0 value in order to support Assemblers that do not recognize the *sync* mnemonic.

Note: *sync* serves as both a basic and an extended mnemonic. The Assembler will recognize a *sync* mnemonic with one operand as the basic form, and a *sync* mnemonic with no operand as the extended form. In the extended form the L operand is omitted and assumed to be 0.

sync (equivalent to: sync 0)
msync<E> (equivalent to: sync 0)
lwsync (equivalent to: sync 1)
ptesync<S> (equivalent to: sync 2)

A.4 Wait Mnemonics

The WC field in the *wait* instruction determines the condition that causes instruction execution to resume. Extended mnemonics are provided that represent the WC value in the mnemonic rather than requiring it to be coded as a numeric operand.

Note: *wait* serves as both a basic and an extended mnemonic. The Assembler will recognize a *wait* mnemonic with one operand as the basic form, and a *wait* mnemonic with no operands as the extended form. In the extended form the WC operand is omitted and assumed to be 0.

wait (equivalent to: wait 0)
waitrsv (equivalent to: wait 1)
waitimpl (equivalent to: wait 2)

Appendix B. Programming Examples for Sharing Storage

This appendix gives examples of how dependencies and the *Synchronization* instructions can be used to control storage access ordering when storage is shared between programs.

Many of the examples use extended mnemonics (e.g., ***bne***, ***bne-***, ***cmpw***) that are defined in Appendix E of Book I.

Many of the examples use the *Load And Reserve* and *Store Conditional* instructions, in a sequence that begins with a *Load And Reserve* instruction and ends with a *Store Conditional* instruction (specifying the same storage location as the *Load Conditional*) followed by a *Branch Conditional* instruction that tests whether the *Store Conditional* instruction succeeded.

In these examples it is assumed that contention for the shared resource is low; the conditional branches are optimized for this case by using “+” and “-” suffixes appropriately.

The examples deal with words; they can be used for doublewords by changing all word-specific mnemonics to the corresponding doubleword-specific mnemonics (e.g., ***lwarx*** to ***ldarx***, ***cmpw*** to ***cmpd***).

In this appendix it is assumed that all shared storage locations are in storage that is Memory Coherence Required, and that the storage locations specified by *Load And Reserve* and *Store Conditional* instructions are in storage that is neither Write Through Required nor Caching Inhibited.

B.1 Atomic Update Primitives

This section gives examples of how the *Load And Reserve* and *Store Conditional* instructions can be used to emulate atomic read/modify/write operations.

An atomic read/modify/write operation reads a storage location and writes its next value, which may be a function of its current value, all as a single atomic operation. The examples shown provide the effect of an atomic read/modify/write operation, but use several instructions rather than a single atomic instruction.

Fetch and No-op

The “Fetch and No-op” primitive atomically loads the current value in a word in storage.

In this example it is assumed that the address of the word to be loaded is in GPR 3 and the data loaded are returned in GPR 4.

```
loop:
  lwarx  r4,0,r3 #load and reserve
  stwcx. r4,0,r3 #store old value if
          # still reserved
  bne-  loop    #loop if lost reservation
```

Note:

1. The ***stwcx.***, if it succeeds, stores to the target location the same value that was loaded by the preceding ***lwarx.*** While the store is redundant with respect to the value in the location, its success ensures that the value loaded by the ***lwarx*** is still the current value at the time the ***stwcx.*** is executed.

Fetch and Store

The “Fetch and Store” primitive atomically loads and replaces a word in storage.

In this example it is assumed that the address of the word to be loaded and replaced is in GPR 3, the new value is in GPR 4, and the old value is returned in GPR 5.

```
loop:
  lwarx  r5,0,r3 #load and reserve
  stwcx. r4,0,r3 #store new value if
          # still reserved
  bne-  loop    loop if lost reservation
```

Fetch and Add

The “Fetch and Add” primitive atomically increments a word in storage.

In this example it is assumed that the address of the word to be incremented is in GPR 3, the increment is in GPR 4, and the old value is returned in GPR 5.

```
loop:
  lwarx  r5,0,r3 #load and reserve
  add    r0,r4,r5#increment word
  stwcx. r0,0,r3 #store new value if still res'ved
  bne-   loop   #loop if lost reservation
```

Fetch and AND

The “Fetch and AND” primitive atomically ANDs a value into a word in storage.

In this example it is assumed that the address of the word to be ANDed is in GPR 3, the value to AND into it is in GPR 4, and the old value is returned in GPR 5.

```
loop:
  lwarx  r5,0,r3 #load and reserve
  and    r0,r4,r5#AND word
  stwcx. r0,0,r3 #store new value if still res'ved
  bne-   loop   #loop if lost reservation
```

Note:

1. The sequence given above can be changed to perform another Boolean operation atomically on a word in storage, simply by changing the **and** instruction to the desired Boolean instruction (**or**, **xor**, etc.).

Test and Set

This version of the “Test and Set” primitive atomically loads a word from storage, sets the word in storage to a nonzero value if the value loaded is zero, and sets the EQ bit of CR Field 0 to indicate whether the value loaded is zero.

In this example it is assumed that the address of the word to be tested is in GPR 3, the new value (nonzero) is in GPR 4, and the old value is returned in GPR 5.

```
loop:
  lwarx  r5,0,r3 #load and reserve
  cmpwi  r5,0    #done if word not equal to 0
  bne-   exit
  stwcx. r4,0,r3 #try to store non-0
  bne-   loop   #loop if lost reservation
exit: ...
```

Compare and Swap

The “Compare and Swap” primitive atomically compares a value in a register with a word in storage, if they are equal stores the value from a second register into the word in storage, if they are unequal loads the word from storage into the first register, and sets the EQ bit of CR Field 0 to indicate the result of the comparison.

In this example it is assumed that the address of the word to be tested is in GPR 3, the comparand is in GPR 4 and the old value is returned there, and the new value is in GPR 5.

```
loop:
  lwarx  r6,0,r3 #load and reserve
  cmpw   r4,r6   #1st 2 operands equal?
  bne-   exit    #skip if not
  stwcx. r5,0,r3 #store new value if still res'ved
  bne-   loop    #loop if lost reservation
exit:
  mr     r4,r6   #return value from storage
```

Notes:

1. The semantics given for “Compare and Swap” above are based on those of the IBM System/370 Compare and Swap instruction. Other architectures may define a Compare and Swap instruction differently.
2. “Compare and Swap” is shown primarily for pedagogical reasons. It is useful on machines that lack the better synchronization facilities provided by **lwarx** and **stwcx.** A major weakness of a System/370-style Compare and Swap instruction is that, although the instruction itself is atomic, it checks only that the old and current values of the word being tested are equal, with the result that programs that use such a Compare and Swap to control a shared resource can err if the word has been modified and the old value subsequently restored. The sequence shown above has the same weakness.
3. In some applications the second **bne-** instruction and/or the **mr** instruction can be omitted. The **bne-** is needed only if the application requires that if the EQ bit of CR Field 0 on exit indicates “not equal” then (r4) and (r6) are in fact not equal. The **mr** is needed only if the application requires that if the comparands are not equal then the word from storage is loaded into the register with which it was compared (rather than into a third register). If either or both of these instructions is omitted, the resulting Compare and Swap does not obey System/370 semantics.

B.2 Lock Acquisition and Release, and Related Techniques

This section gives examples of how dependencies and the *Synchronization* instructions can be used to imple-

ment locks, import and export barriers, and similar constructs.

B.2.1 Lock Acquisition and Import Barriers

An “import barrier” is an instruction or sequence of instructions that prevents storage accesses caused by instructions following the barrier from being performed before storage accesses that acquire a lock have been performed. An import barrier can be used to ensure that a shared data structure protected by a lock is not accessed until the lock has been acquired. A *sync* instruction can be used as an import barrier, but the approaches shown below will generally yield better performance because they order only the relevant storage accesses.

B.2.1.1 Acquire Lock and Import Shared Storage

If *lwarx* and *stwcx.* instructions are used to obtain the lock, an import barrier can be constructed by placing an *isync* instruction immediately following the loop containing the *lwarx* and *stwcx.*. The following example uses the “Compare and Swap” primitive to acquire the lock.

In this example it is assumed that the address of the lock is in GPR 3, the value indicating that the lock is free is in GPR 4, the value to which the lock should be set is in GPR 5, the old value of the lock is returned in GPR 6, and the address of the shared data structure is in GPR 9.

```
loop:
    lwarx  r6,0,r3,1 #load lock and reserve
    cmpw  r4,r6     #skip ahead if
    bne-  wait     # lock not free
    stwcx. r5,0,r3  #try to set lock
    bne-  loop     #loop if lost reservation
    isync                #import barrier
    lwz   r7,data1(r9)#load shared data
    .
wait...                #wait for lock to free
```

The hint provided with *lwarx* indicates that after the program acquires the lock variable (i.e. *stwcx.* is successful), it will release it (i.e. store to it) prior to another program attempting to modify it.

The second *bne-* does not complete until CR0 has been set by the *stwcx.*. The *stwcx.* does not set CR0 until it has completed (successfully or unsuccessfully). The lock is acquired when the *stwcx.* completes successfully. Together, the second *bne-* and the subse-

quent *isync* create an import barrier that prevents the load from “data1” from being performed until the branch has been resolved not to be taken.

If the shared data structure is in storage that is neither Write Through Required nor Caching Inhibited, an *lwsync* instruction can be used instead of the *isync* instruction. If *lwsync* is used, the load from “data1” may be performed before the *stwcx.*. But if the *stwcx.* fails, the second branch is taken and the *lwarx* is re-executed. If the *stwcx.* succeeds, the value returned by the load from “data1” is valid even if the load is performed before the *stwcx.*, because the *lwsync* ensures that the load is performed after the instance of the *lwarx* that created the reservation used by the successful *stwcx.*.

B.2.1.2 Obtain Pointer and Import Shared Storage

If *lwarx* and *stwcx.* instructions are used to obtain a pointer into a shared data structure, an import barrier is not needed if all the accesses to the shared data structure depend on the value obtained for the pointer. The following example uses the “Fetch and Add” primitive to obtain and increment the pointer.

In this example it is assumed that the address of the pointer is in GPR 3, the value to be added to the pointer is in GPR 4, and the old value of the pointer is returned in GPR 5.

```
loop:
    lwarx  r5,0,r3 #load pointer and reserve
    add   r0,r4,r5#increment the pointer
    stwcx. r0,0,r3 #try to store new value
    bne-  loop   #loop if lost reservation
    lwz   r7,data1(r5) #load shared data
```

The load from “data1” cannot be performed until the pointer value has been loaded into GPR 5 by the *lwarx*. The load from “data1” may be performed before the *stwcx.*. But if the *stwcx.* fails, the branch is taken and the value returned by the load from “data1” is discarded. If the *stwcx.* succeeds, the value returned by the load from “data1” is valid even if the load is performed before the *stwcx.*, because the load uses the pointer value returned by the instance of the *lwarx* that created the reservation used by the successful *stwcx.*.

An *isync* instruction could be placed between the *bne-* and the subsequent *lwz*, but no *isync* is needed if all accesses to the shared data structure depend on the value returned by the *lwarx*.

B.2.2 Lock Release and Export Barriers

An “export barrier” is an instruction or sequence of instructions that prevents the store that releases a lock from being performed before stores caused by instructions preceding the barrier have been performed. An export barrier can be used to ensure that all stores to a shared data structure protected by a lock will be performed with respect to any other processor before the store that releases the lock is performed with respect to that processor.

B.2.2.1 Export Shared Storage and Release Lock

A *sync* instruction can be used as an export barrier independent of the storage control attributes (e.g., presence or absence of the Caching Inhibited attribute) of the storage containing the shared data structure. Because the lock must be in storage that is neither Write Through Required nor Caching Inhibited, if the shared data structure is in storage that is Write Through Required or Caching Inhibited a *sync* instruction *must* be used as the export barrier.

In this example it is assumed that the shared data structure is in storage that is Caching Inhibited, the address of the lock is in GPR 3, the value indicating that the lock is free is in GPR 4, and the address of the shared data structure is in GPR 9.

```
stw    r7,data1(r9)#store shared data (last)
sync           #export barrier
stw    r4,lock(r3)#release lock
```

The *sync* ensures that the store that releases the lock will not be performed with respect to any other processor until all stores caused by instructions preceding the *sync* have been performed with respect to that processor.

B.2.2.2 Export Shared Storage and Release Lock using *lwsync*

If the shared data structure is in storage that is neither Write Through Required nor Caching Inhibited, an *lwsync* instruction can be used as the export barrier. Using *lwsync* rather than *sync* will yield better performance in most systems.

In this example it is assumed that the shared data structure is in storage that is neither Write Through Required nor Caching Inhibited, the address of the lock is in GPR 3, the value indicating that the lock is free is in GPR 4, and the address of the shared data structure is in GPR 9.

```
stw    r7,data1(r9)#store shared data (last)
lwsync           #export barrier
stw    r4,lock(r3)#release lock
```

The *lwsync* ensures that the store that releases the lock will not be performed with respect to any other processor until all stores caused by instructions preceding the *lwsync* have been performed with respect to that processor.

B.2.3 Safe Fetch

If a load must be performed before a subsequent store (e.g., the store that releases a lock protecting a shared data structure), a technique similar to the following can be used.

In this example it is assumed that the address of the storage operand to be loaded is in GPR 3, the contents of the storage operand are returned in GPR 4, and the address of the storage operand to be stored is in GPR 5.

```
lwz    r4,0(r3)#load shared data
cmpw   r4,r4    #set CR0 to "equal"
bne-   $-8     #branch never taken
stw    r7,0(r5)#store other shared data
```

An alternative is to use a technique similar to that described in Section B.2.1.2, by causing the *stw* to depend on the value returned by the *lwz* and omitting the *cmpw* and *bne-*. The dependency could be created by ANDing the value returned by the *lwz* with zero and then adding the result to the value to be stored by the *stw*. If both storage operands are in storage that is neither Write Through Required nor Caching Inhibited, another alternative is to replace the *cmpw* and *bne-* with an *lwsync* instruction.

B.3 List Insertion

This section shows how the *lwarx* and *stwcx*. instructions can be used to implement simple insertion into a singly linked list. (Complicated list insertion, in which multiple values must be changed atomically, or in which the correct order of insertion depends on the contents of the elements, cannot be implemented in the manner shown below and requires a more complicated strategy such as using locks.)

The “next element pointer” from the list element after which the new element is to be inserted, here called the “parent element”, is stored into the new element, so that the new element points to the next element in the list; this store is performed unconditionally. Then the address of the new element is conditionally stored into the parent element, thereby adding the new element to the list.

In this example it is assumed that the address of the parent element is in GPR 3, the address of the new element is in GPR 4, and the next element pointer is at offset 0 from the start of the element. It is also assumed that the next element pointer of each list element is in a reservation granule separate from that of the next element pointer of all other list elements.

```
loop:
  lwarx  r2,0,r3 #get next pointer
  stw    r2,0(r4)#store in new element
  lwsync or sync #order stw before stwcx
  stwcx. r4,0,r3 #add new element to list
  bne-  loop   #loop if stwcx. failed
```

In the preceding example, if two list elements have next element pointers in the same reservation granule then, in a multiprocessor, “livelock” can occur. (Livelock is a state in which processors interact in a way such that no processor makes forward progress.)

If it is not possible to allocate list elements such that each element's next element pointer is in a different reservation granule, then livelock can be avoided by using the following, more complicated, sequence.

```
      lwz    r2,0(r3)#get next pointer
loop1:
  mr      r5,r2 #keep a copy
  stw    r2,0(r4)#store in new element
  sync           #order stw before stwcx.
              and before lwarx
loop2:
  lwarx  r2,0,r3 #get it again
  cmpw   r2,r5 #loop if changed (someone
  bne-  loop1 # else progressed)
  stwcx. r4,0,r3 #add new element to list
  bne-  loop2 #loop if failed
```

In the preceding example, livelock is avoided by the fact that each processor re-executes the *stw* only if some other processor has made forward progress.

B.4 Notes

1. To increase the likelihood that forward progress is made, it is important that looping on *lwarx/stwcx*. pairs be minimized. For example, in the “Test and Set” sequence shown in Section B.1, this is achieved by testing the old value before attempting the store; were the order reversed, more *stwcx*. instructions might be executed, and reservations might more often be lost between the *lwarx* and the *stwcx*.
2. The manner in which *lwarx* and *stwcx*. are communicated to other processors and mechanisms, and between levels of the storage hierarchy within a given processor, is implementation-dependent. In some implementations performance may be improved by minimizing looping on a *lwarx* instruction that fails to return a desired value. For example, in the “Test and Set” sequence shown in Section B.1, if the programmer wishes to stay in the loop until the word loaded is zero, he could change the “bne- exit” to “bne- loop”. However, in some implementations better performance may be obtained by using an ordinary Load instruction to do the initial checking of the value, as follows.

```
loop:
  lwz    r5,0(r3)#load the word
  cmpwi  r5,0 #loop back if word
  bne-  loop # not equal to 0
  lwarx  r5,0,r3 #try again, reserving
  cmpwi  r5,0 # (likely to succeed)
  bne-  loop
  stwcx. r4,0,r3 #try to store non-0
  bne-  loop #loop if lost reserv'n
```

3. In a multiprocessor, livelock is possible if there is a *Store* instruction (or any other instruction that can clear another processor's reservation; see Section 1.7.3.1) between the *lwarx* and the *stwcx*. of a *lwarx/stwcx*. loop and any byte of the storage location specified by the Store is in the reservation granule. For example, the first code sequence shown in Section B.3 can cause livelock if two list elements have next element pointers in the same reservation granule.

Book III-S:

**Power ISA Operating Environment Architecture - Server
| Environment [Category: Server]**

Chapter 1. Introduction

1.1 Overview	727	1.4 Exceptions	729
1.2 Document Conventions	727	1.5 Synchronization	729
1.2.1 Definitions and Notation	727	1.5.1 Context Synchronization	729
1.2.2 Reserved Fields	728	1.5.2 Execution Synchronization	730
1.3 General Systems Overview	729		

1.1 Overview

Chapter 1 of Book I describes computation modes, document conventions, a general systems overview, instruction formats, and storage addressing. This chapter augments that description as necessary for the Power ISA Operating Environment Architecture.

1.2 Document Conventions

The notation and terminology used in Book I apply to this Book also, with the following substitutions.

- For “system alignment error handler” substitute “Alignment interrupt”.
- For “system data storage error handler” substitute “Data Storage interrupt”, “Hypervisor Data Storage interrupt”, or “Data Segment interrupt”, as appropriate.
- For “system error handler” substitute “interrupt”.
- For “system floating-point enabled exception error handler” substitute “Floating-Point Enabled Exception type Program interrupt”.
- For “system illegal instruction error handler” substitute “Hypervisor Emulation Assistance interrupt”.
- For “system instruction storage error handler” substitute “Instruction Storage interrupt”, “Hypervisor Instruction Storage interrupt”, or “Instruction Segment interrupt”, as appropriate.
- For “system privileged instruction error handler” substitute “Privileged Instruction type Program interrupt”.
- For “system service program” substitute “System Call interrupt”.

- For “system trap handler” substitute “Trap type Program interrupt”.

1.2.1 Definitions and Notation

The definitions and notation given in Book I are augmented by the following.

- Threaded processor, single-threaded processor, thread

A threaded processor implements one or more “threads”, where a thread corresponds to the Book I/II concept of “processor”. That is, the definition of “thread” is the same as the Book I definition of “processor”, and “processor” as used in Books I and II can be thought of as either a single-threaded processor or as one thread of a multi-threaded processor. The only unqualified uses of “processor” in Book III are in resource names (e.g. Processor Identification Register); such uses should be regarded as meaning “threaded processor”. The threads of a multi-threaded processor typically share certain resources, such as the hardware components that execute certain kinds of instructions (e.g., Fixed-Point instructions), certain caches, the address translation mechanism, and certain hypervisor resources.

- **real page**

A unit of real storage that is aligned at a boundary that is a multiple of its size. The real page size is 4KB.

- **context of a program**

The state (e.g., privilege and relocation) in which the program executes. The context is controlled by the contents of certain System Registers, such as the MSR and SDR1, of certain lookaside buffers, such as the SLB and TLB, and of the Page Table.

- **exception**

An error, unusual condition, or external signal, that may set a status bit and may or may not cause an interrupt, depending upon whether the corresponding interrupt is enabled.

- **interrupt**

The act of changing the machine state in response to an exception, as described in Chapter 6. “Interrupts” on page 821.

- **trap interrupt**

An interrupt that results from execution of a *Trap* instruction.

- Additional exceptions to the sequential execution model, beyond those described in the section entitled “Instruction Fetching” in Book I, are the following.

- A System Reset or Machine Check interrupt may occur. The determination of whether an instruction is required by the sequential execution model is not affected by the potential occurrence of a System Reset or Machine Check interrupt. (The determination is affected by the potential occurrence of any other kind of interrupt.)
- A context-altering instruction is executed (Chapter 10. “Synchronization Requirements for Context Alterations” on page 861). The context alteration need not take effect until the required subsequent synchronizing operation has occurred.
- A Reference and Change bit is updated by the thread. The update need not be performed with respect to that thread until the required subsequent synchronizing operation has occurred.
- A *Branch* instruction is executed and the branch is taken. The update of the Come-From Address Register<S> (see Section 8.1.1 of Book III-S) need not occur until a subsequent context synchronizing operation has occurred.

- **“must”**

If hypervisor software violates a rule that is stated using the word “must” (e.g., “this field must be set to 0”), and the rule pertains to the contents of a hypervisor resource, to executing an instruction that can be executed only in hypervisor state, or to accessing storage in real addressing mode, the results are undefined, and may include altering resources belonging to other partitions, causing the system to “hang”, etc.

- **hardware**

Any combination of hard-wired implementation, emulation assist, or interrupt for software assistance. In the last case, the interrupt may be to an

architected location or to an implementation-dependent location. Any use of emulation assists or interrupts to implement the architecture is implementation-dependent.

- **hypervisor privileged**

A term used to describe an instruction or facility that is available only when the thread is in hypervisor state.

- **privileged state and supervisor mode**

Used interchangeably to refer to a state in which privileged facilities are available.

- **problem state and user mode**

Used interchangeably to refer to a state in which privileged facilities are not available.

- */, //, ///, ...* denotes a field that is reserved in an instruction, in a register, or in an architected storage table.

- *?, ??, ???, ...* denotes a field that is implementation-dependent in an instruction, in a register, or in an architected storage table.

1.2.2 Reserved Fields

Book I's description of the handling of reserved bits in System Registers, and of reserved values of defined fields of System Registers, applies also to the SLB. Book I's description of the handling of reserved values of defined fields of System Registers applies also to architected storage tables (e.g., the Page Table).

Some fields of certain architected storage tables may be written to automatically by the hardware, e.g., Reference and Change bits in the Page Table. When the hardware writes to such a table, the following rules are obeyed.

- Unless otherwise stated, no defined field other than the one(s) specifically being updated are modified.
- Contents of reserved fields are either preserved or written as zero.

Programming Note

Software should set reserved fields in the SLB and in architected storage tables to zero, because these fields may be assigned a meaning in some future version of the architecture.

1.3 General Systems Overview

The hardware contains the sequencing and processing controls for instruction fetch, instruction execution, and interrupt action. Most implementations also contain data and instruction caches. Instructions that the processing unit can execute fall into the following classes:

- instructions executed in the Branch Facility
- instructions executed in the Fixed-Point Facility
- instructions executed in the Floating-Point Facility
- instructions executed in the Vector Facility

Almost all instructions executed in the Branch Facility, Fixed-Point Facility, Floating-Point Facility, and Vector Facility are nonprivileged and are described in Book I. Book II may describe additional nonprivileged instructions (e.g., Book II describes some nonprivileged instructions for cache management). Instructions related to the privileged state, control of hardware resources, control of the storage hierarchy, and all other privileged instructions are described here or are implementation-dependent.

1.4 Exceptions

The following augments the exceptions defined in Book I that can be caused directly by the execution of an instruction:

- the execution of a floating-point instruction when $MSR_{FP}=0$ (Floating-Point Unavailable interrupt)
- an attempt to modify a hypervisor resource when the thread is in privileged but non-hypervisor state (see Chapter 2), or an attempt to execute a hypervisor-only instruction (e.g., *tlbie*) when the thread is in privileged but non-hypervisor state
- the execution of a traced instruction (Trace interrupt)
- the execution of a Vector instruction when the vector facility is unavailable (Vector Unavailable interrupt)

1.5 Synchronization

The synchronization described in this section refers to the state of the thread that is performing the synchronization.

1.5.1 Context Synchronization

An instruction or event is *context synchronizing* if it satisfies the requirements listed below. Such instructions and events are collectively called *context synchronizing operations*. The context synchronizing operations are the *isync* instruction, the *System Linkage* instructions, the *mtmsr[d]* instructions with $L=0$, and most interrupts (see Section 6.4).

1. The operation causes instruction dispatching (the issuance of instructions by the instruction fetching mechanism to any instruction execution mechanism) to be halted.
2. The operation is not initiated or, in the case of *isync*, does not complete, until all instructions that

precede the operation have completed to a point at which they have reported all exceptions they will cause.

3. The operation ensures that the instructions that precede the operation will complete execution in the context (privilege, relocation, storage protection, etc.) in which they were initiated, except that the operation has no effect on the context in which the associated Reference and Change bit updates are performed.
4. If the operation directly causes an interrupt (e.g., *sc* directly causes a System Call interrupt) or is an interrupt, the operation is not initiated until no exception exists having higher priority than the exception associated with the interrupt (see Section 6.8).
5. The operation ensures that the instructions that follow the operation will be fetched and executed in the context established by the operation. (This requirement dictates that any prefetched instructions be discarded and that any effects and side effects of executing them out-of-order also be discarded, except as described in Section 5.5, “Performing Operations Out-of-Order”.)

Programming Note

A context synchronizing operation is necessarily execution synchronizing; see Section 1.5.2.

Unlike the *Synchronize* instruction, a context synchronizing operation does not affect the order in which storage accesses are performed.

Item 2 permits a choice only for *isync* (and *sync* and *ptesync*; see Section 1.5.2) because all other execution synchronizing operations also alter context.

1.5.2 Execution Synchronization

An instruction is *execution synchronizing* if it satisfies items 2 and 3 of the definition of context synchronization (see Section 1.5.1). ***sync*** and ***ptesync*** are treated like ***isync*** with respect to item 2. The execution synchronizing instructions are ***sync***, ***ptesync***, the ***mtmsr[d]*** instructions with L=1, and all context synchronizing instructions.

Programming Note

Unlike a context synchronizing operation, an execution synchronizing instruction does not ensure that the instructions following that instruction will execute in the context established by that instruction. This new context becomes effective sometime after the execution synchronizing instruction completes and before or at a subsequent context synchronizing operation.

Chapter 2. Logical Partitioning (LPAR)

2.1 Overview	731	2.6 Processor Compatibility Register (PCR)	735
2.2 Logical Partitioning Control Register (LPCR)	731	2.7 Other Hypervisor Resources	737
2.3 Real Mode Offset Register (RMOR)	734	2.8 Sharing Hypervisor Resources	738
2.4 Hypervisor Real Mode Offset Register (HRMOR)	734	2.9 Hypervisor Interrupt Little-Endian (HILE) Bit	739
2.5 Logical Partition Identification Register (LPIDR)	734		

2.1 Overview

The Logical Partitioning (LPAR) facility permits threads and portions of real storage to be assigned to logical collections called *partitions*, such that a program executing on a thread in one partition cannot interfere with any program executing on a thread in a different partition. This isolation can be provided for both problem state and privileged state programs, by using a layer of trusted software, called a *hypervisor* program (or simply a “hypervisor”), and the resources provided by this facility to manage system resources. (A hypervisor is a program that runs in hypervisor state; see below.)

The number of partitions supported is implementation-dependent.

A thread is assigned to one partition at any given time. A thread can be assigned to any given partition without consideration of the physical configuration of the system (e.g., shared registers, caches, organization of the storage hierarchy), except that threads that share certain hypervisor resources may need to be assigned to the same partition; see Section 2.7. The registers and facilities used to control Logical Partitioning are listed below and described in the following subsections.

Except in the following subsections, references to the “operating system” in this document include the hypervisor unless otherwise stated or obvious from context.

2.2 Logical Partitioning Control Register (LPCR)

The layout of the Logical Partitioning Control Register (LPCR) is shown in Figure 1 below.

Figure 1. Logical Partitioning Control Register

The contents of the LPCR control a number of aspects of the operation of the thread with respect to a logical partition. Below are shown the bit definitions for the LPCR.

Bit	Description
0:2	Virtualization Control (VC)

<p>Controls the virtualization of partition memory. This field contains two subfields, VPM and ISL.</p> <p>0:1 Virtualized Partition Memory (VPM)</p> <p>This field controls whether VPM mode is enabled as specified below. (See Section 5.7.3.4 and Section 5.7.2, “Virtualized Partition Memory (VPM) Mode” for additional information on VPM mode.)</p> <p>Bit Description</p> <p>0 This bit controls whether VPM mode is enabled when address translation is disabled 0 - VPM mode disabled 1 - VPM mode enabled</p> <p>1 This bit controls whether VPM mode is enabled when address translation is enabled 0 - VPM mode disabled 1 - VPM mode enabled</p> <p>2 Ignore SLB Large Page Specification (ISL)</p> <p>Controls whether ISL mode is enabled as specified below.</p> <p>0 - ISL mode disabled 1 - ISL mode enabled</p> <p>When ISL mode is enabled and address translation is enabled and the thread is not in hypervisor state, address translation is performed as if the contents of SLB_{LILP} were 0b000. When address translation is disabled, the setting of the ISL bit has no effect. ISL mode has no effect on SLB, TLB, and ERAT entry invalidations caused by <i>slbie</i>, <i>slbia</i>, <i>tlbia</i>, <i>tlbie</i>, and <i>slbie</i>.</p> <p>3:8 Reserved</p> <p>9:11 Default Prefetch Depth (DPFD)</p> <p>The DPFD field is used as the default prefetch depth for data stream prefetching when DSCR_{DPFD}=0; see page 682.</p> <p>12:16 Virtual Real Mode Area Segment Descriptor (VRMASD)</p> <p>When address translation is disabled and VPM₀=1, the contents of this field specify the L and LP fields of the segment descriptor that apply for storage references to the virtualized real mode area (VRMA). See Section 5.7.3.4 for additional information. The definitions and allowed values of the L and LP fields are the same as for the corresponding fields in the segment descriptor. (See Section 5.7.7.) If</p>	<p>VPM₀=0 or address translation is enabled, the setting of the VRMASD has no effect.</p> <p>Bit Description</p> <p>0 Virtual Page Size Selector Bit 0 (L) 1:2 Reserved 3:4 Virtual Page Size Selector Bits 1:2 (LP)</p> <p>Programming Note</p> <p>17:33 Reserved</p> <p>34:37 Real Mode Limit Selector (RMLS)</p> <p>The RMLS field specifies the largest effective address that can be used by partition software when address translation is disabled. The valid RMLS values are implementation-dependent, and each value corresponds to a maximum effective address of 2^m, where m has a minimum value of 12 and a maximum value equal to the number of bits in the real address size supported by the implementation.</p> <p>38 Interrupt Little-Endian (ILE)</p> <p>The contents of the ILE bit are copied into MSR_{LE} by interrupts that set MSR_{HV} to 0 (see Section 6.5), to establish the Endian mode for the interrupt handler.</p> <p>39:48 Reserved</p> <p>49:51 Power-saving mode Exit Cause Enable (PECE)</p> <p>49 If PECE₀ = 1 when a power-saving mode instruction is executed, External exceptions are enabled to cause exit from power-saving mode; otherwise External exceptions are disabled from causing exit from power-saving mode.</p> <p>50 If PECE₁ = 1 when a power-saving mode instruction is executed, Decrementer exceptions are enabled to cause exit from power-saving mode; otherwise Decrementer exceptions are disabled from causing exit from power-saving mode. (In sleep and rvinkle power-saving levels, Decrementer exceptions do not occur if the state of the Decrementer is not maintained and updated as if the thread was not in power-saving mode.)</p> <p>51 If PECE₂=1 when a power-saving mode instruction is executed, Machine Check, Hypervisor Maintenance, and certain implementation-specific exceptions are enabled to cause exit from power-saving mode; otherwise Machine Check, Hypervisor Maintenance, and the same implementation-specific exceptions are disabled from causing exit from power-saving mode.</p>
--	---

It is implementation-specific whether the exceptions enabled by the PECE field cause exit from sleep and rvwinkle power-saving levels. See Section 6.5.1 and Section 6.5.2 for additional information about exit from power-saving mode.

52 **Mediated External Exception Request (MER)**

0 A Mediated External exception is not requested.

1 A Mediated External exception is requested.

The exception effects of this bit are said to be consistent with the contents of this bit if one of the following statements is true.

- $LPCR_{MER} = 1$ and a Mediated External exception exists.
- $LPCR_{MER} = 0$ and a Mediated External exception does not exist.

A context synchronizing instruction or event that is executed or occurs when $LPCR_{MER} = 0$ ensures that the exception effects of $LPCR_{MER}$ are consistent with the contents of $LPCR_{MER}$. Otherwise, when an instruction changes the contents of $LPCR_{MER}$, the exception effects of $LPCR_{MER}$ become consistent with the new contents of $LPCR_{MER}$ reasonably soon after the change.

Programming Note

$LPCR_{MER}$ provides a means for the hypervisor to direct an external exception to a partition independent of the partition's MSR_{EE} setting. (When $MSR_{EE}=0$, it is inappropriate for the hypervisor to deliver the exception.) Using $LPCR_{MER}$, the partition can be interrupted upon enabling external interrupts. Without using $LPCR_{MER}$, the hypervisor must check the state of MSR_{EE} whenever it gets control, which will result in less timely delivery of the exception to the partition.

53 Reserved

54 **Translation Control (TC)**

0 The secondary Page Table search is enabled.

1 The secondary Page Table search is disabled.

55:59 Reserved

60:61 **Logical Partitioning Environment Selector (LPES)**

Three of the four LPES values are supported. The 0b10 value is reserved.

60 $LPES_0$

Controls whether External interrupts set MSR_{HV} to 1 and MSR_{RI} to 0, or leaves them unchanged.

61 $LPES_1$

Controls how storage is accessed when address translation is disabled, and whether a subset of interrupts set MSR_{HV} to 1.

Programming Note

$LPES_1=0$ provides an environment in which only the hypervisor can run with address translation disabled and in which all interrupts invoke the hypervisor. This value (along with $MSR_{HV}=1$) can also be used in a system that is not partitioned, to permit the operating system to access all system resources.

62 Reserved

63 **Hypervisor Decrementer Interrupt Conditionally Enable (HDICE)**

0 Hypervisor Decrementer interrupts are disabled.

1 Hypervisor Decrementer interrupts are enabled if permitted by MSR_{EE} , MSR_{HV} , and MSR_{PR} ; see Section 6.5.12 on page 839.

See Section 5.7.3 on page 774 (including subsections) and Section 5.7.9 on page 790 for a description of how storage accesses are affected by the setting of $LPES_1$, and $RMLS$. See Section 6.5 on page 828 for a description of how the setting of $LPES_{0:1}$ affects the processing of interrupts.

2.3 Real Mode Offset Register (RMOR)

The layout of the Real Mode Offset Register (RMOR) is shown in Figure 2 below.

Bits	Name	Description
4:63	RMO	Real Mode Offset

Figure 2. Real Mode Offset Register

All other fields are reserved.

The supported RMO values are the non-negative multiples of 2^5 , where 2^5 is the smallest implementation-dependent limit value representable by the contents of the Real Mode Limit Selector field of the $LPCR$.

The contents of the RMOR affect how some storage accesses are performed as described in Section 5.7.3 on page 774 and Section 5.7.4 on page 777.

2.4 Hypervisor Real Mode Offset Register (HRMOR)

The layout of the Hypervisor Real Mode Offset Register (HRMOR) is shown in Figure 3 below.

Bits	Name	Description
4:63	HRMO	Real Mode Offset

Figure 3. Hypervisor Real Mode Offset Register

All other fields are reserved.

The supported HRMO values are the non-negative multiples of 2^r , where r is an implementation-dependent value and $12 \leq r \leq 26$.

The contents of the HRMOR affect how some storage accesses are performed as described in Section 5.7.3 on page 774 and Section 5.7.4 on page 777.

2.5 Logical Partition Identification Register (LPIDR)

The layout of the Logical Partition Identification Register (LPIDR) is shown in Figure 4 below.

Bits	Name	Description
32:63	LPID	Logical Partition Identifier

Figure 4. Logical Partition Identification Register

The contents of the LPIDR identify the partition to which the thread is assigned, affecting operations necessary to manage the coherency of some translation lookaside buffers (see Section 5.10.1 and Chapter 10.). The number of LPIDR bits supported is implementation-dependent.

Programming Note

On some implementations, software must prevent the execution of a *tlbie* instruction with an LPID operand value which matches the contents of another thread's LPIDR that is being modified or is the same as the new value being written to the LPIDR. This restriction can be met with less effort if one partition identity is used only on threads on which no *tlbie* instruction is ever executed. This partition can be thought of as the transfer partition used exclusively to move a thread from one partition to another.

2.6 Processor Compatibility Register (PCR)

The layout of the Processor Compatibility Register (PCR) is shown in Figure 5 below.

Figure 5. Processor Compatibility Register

Starting from bit 0, high-order PCR bits are assigned to control the availability of certain categories. Starting from bit 63, low-order PCR bits are assigned to control the availability of resources that are new in a specified version of the Architecture. These low-order bits have the possibility of subsetting the function provided by a category for which availability is controlled by the high-order bits. For example, if a new function is added to Vector category in V 2.06, the V 2.05 bit and the VEC bits may be used together to enable a version of the Vector category that was available in V 2.05.

Each defined bit in the PCR controls whether certain instructions, SPRs, and other related facilities are available in problem state. Except as specified elsewhere in this section, the PCR has no effect on facilities when the thread is not in problem state. Facilities that are made unavailable by the PCR are treated as follows when the thread is in problem state.

- Instructions are treated as illegal instructions,
- SPRs are treated as if they were not defined for the implementation
- Fields in instructions are treated as if they were 0s.

A PCR bit may also determine how an instruction field value is interpreted or may define other behavior as specified in the bit definitions below.

The PCR has no effect on the setting of the MSR and [H]SRR1 by interrupts, and by the *[h]rfid* and *mtmsr[d]* instructions, except as specified elsewhere in this section.

When facilities that have enable bits in the MSR are made unavailable by the value in the PCR (e.g. Vector Facility), they become unavailable as specified above regardless of whether they are enabled by the corresponding MSR bit.

The bit definitions for the PCR are shown below.

Bit	Description
0	<p>Vector (VEC) [Category: Vector]</p> <p>This bit controls the availability, in problem state, of the instructions and facilities in the Vector category as it is defined in the latest version of the architecture for which new problem-state resources are made available.</p> <p>0 The instructions and facilities in the Vector category are available in problem state.</p> <p>1 The instructions and facilities in the Vector category are unavailable in problem state.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p style="text-align: center;">Programming Note</p> <p>Since the category of the VRSAVE register was changed from Vector to Base in versions of the architecture subsequent to Version 2.05, the availability of the VRSAVE register in problem state is controlled by the Vector bit only when the Version 2.05 bit is set to 1.</p> </div>
1	<p>VSX [Category: VSX]</p> <p>This bit controls the availability, in problem state, of the instructions and facilities in the VSX category as it was defined in the latest version of the architecture for which new problem-state resources are made available; if the VSX category was not defined in that version of the architecture, then VSX instructions and facilities are unavailable.</p> <p>0 The instructions and facilities in the VSX category are available in problem state.</p> <p>1 The instructions and facilities in the VSX category are unavailable in problem state.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p style="text-align: center;">Programming Note</p> <p>Since facilities in the VSX category were not defined in Version 2.05, these facilities are not available in problem state when the v2.05 bit is set to 1 regardless of the value of the VSX bit.</p> </div>
2:61	Reserved
62	<p>Version 2.05 (v2.05)</p> <p>This bit controls the availability, in problem state, of the following instructions, facilities, and behaviors that were newly available in problem state in the version of the architecture subsequent to Version 2.05.</p>

- AMR access using SPR 13
- *addg6s*
- *bperm*
- *cdtbcd, cbcdd*
- *dcffix[.]*
- *divde[o][.], divdeu[o][.], divwe[o][.], divweu[o][.]*
- *isel*
- *lfiwzx* [Category: Floating-Point: Phased-In]
- *fctidu[.], fctiduz[.], fctiwu[.], fctiwuz[.], fcfids[.], fcfidu[.], fcfidus[.], ftdiv, ftsqrt* [Category: Floating-Point: Phased-In]
- *ldbrx, stdbrx* [Category: 64-bit]
- *popcntw, popcntd*

0 The listed instructions, facilities, and behaviors are available in the privilege states specified above.

1 The listed instructions, facilities, and behaviors are unavailable in the privilege states specified above.

Programming Note

The definition of the VSX bit makes facilities in the VSX category unavailable in problem state when the v2.05 bit is set to 1 since these facilities were not defined in Version 2.05. See the VSX bit definition for additional information.

63 Reserved

The initial state of the PCR is all 0s.

Programming Note

Because the PCR has no effect on privileged instructions except as specified above, privileged instructions that are available on newer implementations but not available on older implementations will behave differently when the thread is in problem state. On older implementations, either an Illegal Instruction type Program interrupt or a Hypervisor Emulation Assistance interrupt will occur because the instruction is undefined; on newer implementations, a Privileged Instruction type Program interrupt will occur because the instruction is implemented. (On older implementations the interrupt will be an Illegal Instruction type Program interrupt if the implementation complies with a version of the architecture that precedes V. 2.05, or complies with V. 2.05 and does not support the Hypervisor Emulation Assistance category, and will be a Hypervisor Emulation Assistance interrupt otherwise.)

In future versions of the architecture, in general the lowest-order reserved bit of the PCR will be used to control the availability of the instructions and related resources that are new in that version of the architecture; the name of the bit will correspond to the previous version of the architecture (i.e. the newest version in which the instructions and related resources were not available).

In these future versions of the architecture, there will be a requirement that if any bit of the low-order defined bits is set to 1 then all higher-order bits of the defined low-order bits must also be set to 1, and the architecture version with which the implementation appears to comply, in problem state, will be the version corresponding to the name of the lowest-order 1 bit in the set of defined low-order PCR bits, or the current architecture version if none of these bits are 1. Also, in general the highest-order reserved bits will be used to control the availability of sets of instructions and related resources having the requirement that their availability be independent of versions of the architecture.

2.7 Other Hypervisor Resources

In addition to the resources described above, all hypervisor privileged instructions as well as the following resources are hypervisor resources, accessible to software only when the thread is in hypervisor state except as noted below.

- All implementation-specific resources, including implementation-specific registers (e.g., “HID” registers), that control hardware functions or affect the results of instruction execution. Examples include resources that disable caches, disable hardware

error detection, set breakpoints, control power management, or significantly affect performance.

- ME bit of the MSR
- SPRs defined as hypervisor-privileged in Section 4.4.4. (Note: Although the Time Base, the PURR, and the SPURR can be altered only by a hypervisor program, the Time Base can be read by all programs and the PURR and SPURR can be read when the thread is in privileged state.)

The contents of a hypervisor resource can be modified by the execution of an instruction (e.g., *mtspr*) only in hypervisor state ($MSR_{HV\ PR} = 0b10$). An attempt to modify the contents of a given hypervisor resource, other than MSR_{ME} , in privileged but non-hypervisor state ($MSR_{HV\ PR} = 0b00$) causes a Privileged Instruction type Program interrupt. An attempt to modify MSR_{ME} in privileged but non-hypervisor state is ignored (i.e., the bit is not changed).

Programming Note

Because the SPRs listed above are privileged for writing, an attempt to modify the contents of any of these SPRs in problem state ($MSR_{PR}=1$) using *mtspr* causes a Privileged Instruction type Program exception, and similarly for MSR_{ME} .

2.8 Sharing Hypervisor Resources

Some hypervisor resources may be shared among threads. Programs that modify these resources must be aware of this sharing, and must allow for the fact that changes to these resources may affect more than one thread. The following resources may be shared among threads.

- RMOR (see Section 2.3)
- HRMOR (see Section 2.4)
- LPIDR (see Section 2.5)
- PCR [Category: Processor Control] (see Section 2.6)
- PVR (see Section 4.3.1)
- SDR1 (see Section 5.7.7.2)
- AMOR (see Section 5.7.9.1)
- HMEER (see Section 6.2.9)
- Time Base (see Section 7.2)
- Hypervisor Decrementer (see Section 7.4)
- certain implementation-specific registers or implementation-specific fields in architected registers

The set of resources that are shared is implementation-dependent.

Threads that share any of the resources listed above, with the exception of the PVR and the HRMOR, must be in the same partition.

For each field of the LPCR, except the HDICE field and the MER field, software must ensure that the contents of the field are identical among all threads that are in the same partition and are in a state such that the contents of the field could have side effects. (E.g., software must ensure that the contents of $LPCR_{LPES}$ are identical among all threads that are in the same partition and are not in hypervisor state.) For the HDICE field, software must ensure that the contents of the field are identical among all threads that share the Hypervisor Decrementer and are in a state such that the contents of the field could have side effects. (There are no identity requirements for the MER field).

2.9 Hypervisor Interrupt Little-Endian (HILE) Bit

The Hypervisor Interrupt Little-Endian (HILE) bit is a bit in an implementation-dependent register or similar mechanism. The contents of the HILE bit are copied into MSR_{LE} by interrupts that set MSR_{HV} to 1 (see Section 6.5), to establish the Endian mode for the interrupt handler. The HILE bit is set, by an implementation-dependent method, during system initialization, and cannot be modified after system initialization.

The contents of the HILE bit must be the same for all threads under the control of a given instance of the hypervisor; otherwise all results are undefined.

Chapter 3. Branch Facility

3.1 Branch Facility Overview	741	3.3.2 Power-Saving Mode Instructions	747
3.2 Branch Facility Registers	741	3.3.2.1 Entering and Exiting Power-Saving Mode	751
3.2.1 Machine State Register	741		
3.3 Branch Facility Instructions	745		
3.3.1 System Linkage Instructions	745		

3.1 Branch Facility Overview

This chapter describes the details concerning the registers and the privileged instructions implemented in the Branch Facility that are not covered in Book I.

3.2 Branch Facility Registers

3.2.1 Machine State Register

The Machine State Register (MSR) is a 64-bit register. This register defines the state of the thread. On interrupt, the MSR bits are altered in accordance with Figure 44 on page 828. The MSR can also be modified by the *mtmsr[d]*, *rfid*, and *hrfid* instructions. It can be read by the *mfmsr* instruction.

Figure 6. Machine State Register

Below are shown the bit definitions for the Machine State Register.

Bit	Description
0	Sixty-Four-Bit Mode (SF)
0	The thread is in 32-bit mode.
1	The thread is in 64-bit mode.
1:2	Reserved
3	Hypervisor State (HV)
0	The thread is not in hypervisor state.
1	If MSR _{PR} =0 the thread is in hypervisor state; otherwise the thread is not in hypervisor state.

Programming Note

The privilege state of the thread is determined by MSR_{HV} and MSR_{PR}, as follows.

HV	PR	
0	0	privileged
0	1	problem
1	0	privileged and hypervisor
1	1	problem

MSR_{HV} can be set to 1 only by the *System Call* instruction and some interrupts. It can be set to 0 only by *rfid* and *hrfid*.

4:37	Reserved
38	Vector Available (VEC) [Category: Vector]
0	The thread cannot execute any vector instructions, including vector loads, stores, and moves.
1	The thread can execute vector instructions.
39	Reserved

40	VSX Available (VSX)				
	0	The thread cannot execute any VSX instructions, including VSX loads, stores, and moves.			unless that instruction is <i>hrfid</i> or <i>rfid</i> , which are never traced. Successful completion means that the instruction caused no other interrupt.
	1	The thread can execute VSX instructions.	54	Branch Trace Enable (BE)	
41:46	Reserved			[Category: Trace]	
47	Reserved			0	The thread executes branch instructions normally.
48	External Interrupt Enable (EE)			1	The thread generates a Branch type Trace interrupt after completing the execution of a branch instruction, whether or not the branch is taken.
	0	External and Decrementer interrupts are disabled.			
	1	External and Decrementer interrupts are enabled.			
		This bit also affects whether Hypervisor Decrementer and Hypervisor Maintenance interrupts are enabled; see Section 6.5.12 on page 839 and Section 6.2.9 on page 823.			Branch tracing need not be supported on all implementations that support the Trace category. If the function is not implemented, this bit is treated as reserved.
49	Problem State (PR)		55	Floating-Point Exception Mode 1 (FE1)	
	0	The thread is in privileged state.		[Category: Floating-Point]	
	1	The thread is in problem state.		See below.	
		Programming Note	56:57	Reserved	
		Any instruction that sets MSR _{PR} to 1 also sets MSR _{EE} , MSR _{IR} , and MSR _{DR} to 1.	58	Instruction Relocate (IR)	
50	Floating-Point Available (FP)			0	Instruction address translation is disabled.
	[Category: Floating-Point]			1	Instruction address translation is enabled.
	0	The thread cannot execute any floating-point instructions, including floating-point loads, stores, and moves.			Programming Note
	1	The thread can execute floating-point instructions.			See the Programming Note in the definition of MSR _{PR} .
51	Machine Check Interrupt Enable (ME)		59	Data Relocate (DR)	
	0	Machine Check interrupts are disabled.		0	Data address translation is disabled. Effective Address Overflow (EAO) (see Book I) does not occur.
	1	Machine Check interrupts are enabled.		1	Data address translation is enabled. EAO causes a Data Storage interrupt.
		This bit is a hypervisor resource; see Chapter 2., “Logical Partitioning (LPAR)”, on page 731.			Programming Note
		Programming Note			See the Programming Note in the definition of MSR _{PR} .
		The only instructions that can alter MSR _{ME} are <i>rfid</i> and <i>hrfid</i> .	60	Reserved	
52	Floating-Point Exception Mode 0 (FE0)		61	Performance Monitor Mark (PMM)	
	[Category: Floating-Point]			[Category: Server.Performance Monitor]	
	See below.			See Appendix B of Book III-S.	
53	Single-Step Trace Enable (SE)		62	Recoverable Interrupt (RI)	
	[Category: Trace]			0	Interrupt is not recoverable.
	0	The thread executes instructions normally.		1	Interrupt is recoverable.
	1	The thread generates a Single-Step type Trace interrupt after successfully completing the execution of the next instruction,	63	Little-Endian Mode (LE)	

- 0 The thread is in Big-Endian mode.
- 1 The thread is in Little-Endian mode.

Programming Note

The only instructions that can alter MSR_{LE} are *rfid* and *hrfid*.

The Floating-Point Exception Mode bits FE0 and FE1 are interpreted as shown below. For further details see Book I.

FE0	FE1	Mode
0	0	Ignore Exceptions
0	1	Imprecise Nonrecoverable
1	0	Imprecise Recoverable
1	1	Precise

3.3 Branch Facility Instructions

3.3.1 System Linkage Instructions

These instructions provide the means by which a program can call upon the system to perform a service, and by which the system can return from performing a service or from processing an interrupt.

The *System Call* instruction is described in Book I, but only at the level required by an application programmer. A complete description of this instruction appears below.

System Call

SC-form

sc LEV

17	///	///	//	LEV	//	1	/
0	6	11	16	20	27	30	31

```
SRR0 ←iea CIA + 4
SRR133:36 42:47 ← 0
SRR10:32 37:41 48:63 ← MSR0:32 37:41 48:63
MSR ← new_value (see below)
NIA ← 0x0000_0000_0000_0C00
```

The effective address of the instruction following the *System Call* instruction is placed into SRR0. Bits 0:32, 37:41, and 48:63 of the MSR are placed into the corresponding bits of SRR1, and bits 33:36 and 42:47 of SRR1 are set to zero.

Then a System Call interrupt is generated. The interrupt causes the MSR to be set as described in Section 6.5, “Interrupt Definitions” on page 828. The setting of the MSR is affected by the contents of the LEV field. LEV values greater than 1 are reserved. Bits 0:5 of the LEV field (instruction bits 20:25) are treated as a reserved field.

The interrupt causes the next instruction to be fetched from effective address 0x0000_0000_0000_0C00.

This instruction is context synchronizing.

Special Registers Altered:

SRR0 SRR1 MSR

Programming Note

If LEV=1 the hypervisor is invoked.

If LPES₁=1, executing this instruction with LEV=1 is the only way that executing an instruction can cause hypervisor state to be entered.

Because this instruction is not privileged, it is possible for application software to invoke the hypervisor. However, such invocation should be considered a programming error.

Programming Note

sc serves as both a basic and an extended mnemonic. The Assembler will recognize an **sc** mnemonic with one operand as the basic form, and an **sc** mnemonic with no operand as the extended form. In the extended form the LEV operand is omitted and assumed to be 0.

Return From Interrupt Doubleword XL-form

rfid

0	19	///	///	///	18	/
	6	11	16	21	31	

$$\begin{aligned} \text{MSR}_{51} &\leftarrow (\text{MSR}_3 \& \text{SRR1}_{51}) \mid ((\neg \text{MSR}_3) \& \text{MSR}_{51}) \\ \text{MSR}_3 &\leftarrow \text{MSR}_3 \& \text{SRR1}_3 \\ \text{MSR}_{48} &\leftarrow \text{SRR1}_{48} \mid \text{SRR1}_{49} \\ \text{MSR}_{58} &\leftarrow \text{SRR1}_{58} \mid \text{SRR1}_{49} \\ \text{MSR}_{59} &\leftarrow \text{SRR1}_{59} \mid \text{SRR1}_{49} \\ \text{MSR}_{0:2 \ 4:32 \ 37:41 \ 49:50 \ 52:57 \ 60:63} &\leftarrow \text{SRR1}_{0:2 \ 4:32 \ 37:41 \ 49:50 \ 52:57 \ 60:63} \\ \text{NIA} &\leftarrow_{\text{iea}} \text{SRR0}_{0:61} \mid \mid 0\text{b}00 \end{aligned}$$

If $\text{MSR}_3=1$ then bits 3 and 51 of SRR1 are placed into the corresponding bits of the MSR. The result of ORing bits 48 and 49 of SRR1 is placed into MSR_{48} . The result of ORing bits 58 and 49 of SRR1 is placed into MSR_{58} . The result of ORing bits 59 and 49 of SRR1 is placed into MSR_{59} . Bits 0:2, 4:32, 37:41, 49:50, 52:57, and 60:63 of SRR1 are placed into the corresponding bits of the MSR.

If the new MSR value does not enable any pending exceptions, then the next instruction is fetched, under control of the new MSR value, from the address $\text{SRR0}_{0:61} \mid \mid 0\text{b}00$ (when $\text{SF}=1$ in the new MSR value) or $^{32}0 \mid \mid \text{SRR0}_{32:61} \mid \mid 0\text{b}00$ (when $\text{SF}=0$ in the new MSR value). If the new MSR value enables one or more pending exceptions, the interrupt associated with the highest priority pending exception is generated; in this case the value placed into SRR0 or HSRR0 by the interrupt processing mechanism (see Section 6.4.3) is the address of the instruction that would have been executed next had the interrupt not occurred.

This instruction is privileged and context synchronizing.

Special Registers Altered:

MSR

Programming Note

If this instruction sets MSR_{PR} to 1, it also sets MSR_{EE} , MSR_{IR} , and MSR_{DR} to 1.

Hypervisor Return From Interrupt Doubleword XL-form

hrfid

0	19	///	///	///	274	/
	6	11	16	21	31	

$$\begin{aligned} \text{MSR}_{48} &\leftarrow \text{HSRR1}_{48} \mid \text{HSRR1}_{49} \\ \text{MSR}_{58} &\leftarrow \text{HSRR1}_{58} \mid \text{HSRR1}_{49} \\ \text{MSR}_{59} &\leftarrow \text{HSRR1}_{59} \mid \text{HSRR1}_{49} \\ \text{MSR}_{0:32 \ 37:41 \ 49:57 \ 60:63} &\leftarrow \text{HSRR1}_{0:32 \ 37:41 \ 49:57 \ 60:63} \\ \text{NIA} &\leftarrow_{\text{iea}} \text{HSRR0}_{0:61} \mid \mid 0\text{b}00 \end{aligned}$$

The result of ORing bits 48 and 49 of HSRR1 is placed into MSR_{48} . The result of ORing bits 58 and 49 of HSRR1 is placed into MSR_{58} . The result of ORing bits 59 and 49 of HSRR1 is placed into MSR_{59} . Bits 0:32, 37:41, 49:57, and 60:63 of HSRR1 are placed into the corresponding bits of the MSR.

If the new MSR value does not enable any pending exceptions, then the next instruction is fetched, under control of the new MSR value, from the address $\text{HSRR0}_{0:61} \mid \mid 0\text{b}00$ (when $\text{SF}=1$ in the new MSR value) or $^{32}0 \mid \mid \text{HSRR0}_{32:61} \mid \mid 0\text{b}00$ (when $\text{SF}=0$ in the new MSR value). If the new MSR value enables one or more pending exceptions, the interrupt associated with the highest priority pending exception is generated; in this case the value placed into SRR0 or HSRR0 by the interrupt processing mechanism (see Section 6.4.3) is the address of the instruction that would have been executed next had the interrupt not occurred.

This instruction is hypervisor privileged and context synchronizing.

Special Registers Altered:

MSR

Programming Note

If this instruction sets MSR_{PR} to 1, it also sets MSR_{EE} , MSR_{IR} , and MSR_{DR} to 1.

3.3.2 Power-Saving Mode Instructions

The power-saving mode instructions provide a means by which the hypervisor can put the thread into power-saving mode. When the thread is in power-saving mode it does not execute instructions, and it may consume less power than it would consume when it is not in power-saving mode.

There are four levels of power-savings, called doze, nap, sleep, and rwinkle. For each level in this list, the power consumed is less than or equal to the power consumed in the preceding level, and the time required for the thread to exit from the level and for software then to resume normal operation is greater than or equal to the corresponding time for the preceding level. Doze power-saving level requires a minimum amount of such time, while the other levels may require more time. Resources other than those listed in the instruction descriptions that are maintained in each level other than doze, and the actions required by the hypervisor in order for software to resume normal operation after the

thread exits from power-saving mode, are implementation-specific.

Read-only resources (including the HILE bit) are maintained in all power-saving levels. Descriptions of resource state loss in the power-saving mode instruction descriptions do not apply to read-only resources.

Programming Note

The hypervisor determines which power-saving level to enter based on how responsive the system needs to be. If the hypervisor decides that some loss of state is acceptable, it can use the *nap* instruction rather than the *doze* instruction, and when the thread exits from power-saving mode the hypervisor can quickly determine whether any resources need to be restored.

Doze**XL-form**

doze

The thread is placed into doze power-saving level.

When the thread is in doze power-saving level, the state of all thread resources is maintained as if the thread was not in power-saving mode.

When the interrupt that causes exit from doze power-saving level occurs, resource state is as described in the preceding paragraph, except that if the exception that caused the exit is a System Reset, Machine Check, or Hypervisor Maintenance exception, resource state that would be lost if the exception occurred when the thread was not in power-saving mode may be lost.

This instruction is hypervisor privileged and context synchronizing.

Special Registers Altered:

None

Nap**XL-form**

nap

The thread is placed into nap power-saving level.

When the thread is in nap power-saving level, the state of the Decrementer and all hypervisor resources is maintained as if the thread was not in power-saving mode, and sufficient information is maintained to allow the hypervisor to resume execution.

When the interrupt that causes exit from nap power-saving level occurs, resource state is as described in the preceding paragraph, except that if the exception that caused the exit is a System Reset, Machine Check, or Hypervisor Maintenance exception, resource state that would be lost if the exception occurred when the thread was not in power-saving mode may be lost.

This instruction is hypervisor privileged and context synchronizing.

Special Registers Altered:

None

Programming Note

If the state of the Decrementer were not maintained and updated as if the thread was not in power-saving mode, Decrementer exceptions would not reliably cause exit from nap power-saving level even if Decrementer exceptions were enabled to cause exit.

Sleep**XL-form**

sleep

The thread is placed into sleep power-saving level.

When the thread is in sleep power-saving level, the state of all resources may be lost except for the HRMOR.

When the interrupt that causes exit from sleep power-saving level occurs, resource state is as described in the preceding paragraph, except that if the exception that caused the exit is a System Reset, Machine Check, or Hypervisor Maintenance exception, resource state that would be lost if the exception occurred when the thread was not in power-saving mode may be lost.

This instruction is hypervisor privileged and context synchronizing.

Special Registers Altered:

None

Programming Note

If the state of the Decrementer is not maintained and updated, in sleep or *rvwinkle* power-saving level, as if the thread was not in power-saving mode, Decrementer exceptions will not reliably cause exit from power-saving mode even if Decrementer exceptions are enabled to cause exit.

Note

See the Notes that appear in the *rvwinkle* instruction description.

Rip Van Winkle**XL-form**

rwinkle

19	///	///	///	498	/
0	6	11	16	21	31

The thread is placed into rwinkle power-saving level.

When the thread is in rwinkle power-saving level, the state of all resources may be lost except for the HRMOR.

When the interrupt that causes exit from rwinkle power-saving level occurs, resource state is as described in the preceding paragraph, except that if the exception that caused the exit is a System Reset, Machine Check, or Hypervisor Maintenance exception, resource state that would be lost if the exception occurred when the thread was not in power-saving mode may be lost.

This instruction is hypervisor privileged and context synchronizing.

Special Registers Altered:

None

Programming Note

In the short story by Washington Irving, Rip Van Winkle is a man who fell asleep on a green knoll and awoke twenty years later.

Note

See the Notes that appear in the *sleep* instruction description.

3.3.2.1 Entering and Exiting Power-Saving Mode

In order to enter power-saving mode, the hypervisor must use the instruction sequence shown below. Before executing this sequence, the hypervisor must ensure that $LPCR_{MER}$ contains the value 0, the $LPCR_{PECE}$ contains the desired value if doze or nap power-saving level is to be entered, MSR_{SF} , MSR_{HV} , and MSR_{ME} contain the value 1, and all other bits of the MSR contain the value 0 except for MSR_{RI} , which may contain either 0 or 1. Depending on the implementation and on the power-saving mode being entered, it may also be necessary for the hypervisor to save the state of certain resources before entering the sequence. The sequence must be exactly as shown, with no intervening instructions, except that any GPR may be used as Rx and as Ry, and any value may be used for “save_area” provided the resulting effective address is double-word aligned and corresponds to a valid real address.

```

std  Rx,save_area(Ry)  /* last store neces-*/
                          /* sary to save state*/
ptesync                /* order load after*/
                          /* last store    */
ld   Rx,save_area(Ry) /* reload from last */
                          /* store location, */
                          /* for synchro-   */
                          /* nization     */

loop:
  cmp  Rx,Rx            /* create dependency */
  bne  loop
  nap/doze/sleep/rwinkle /* enter power- */
                          /* saving mode   */
  b   $                 /* branch to self */

```

After the thread has entered power-saving mode as specified above, various exceptions may cause exit from power-saving mode. The exceptions include, System Reset, Machine Check, Decrementer, External, Hypervisor Maintenance, and implementation-specific exceptions. Upon exit from power-saving mode, if the exception was a Machine Check exception, then a Machine Check interrupt occurs; otherwise a System Reset interrupt occurs, and the contents of $SRR1$ indicate the type of exception that caused exit from power-saving mode. See Section 6.5.1 for additional information.

Programming Note

The *ptesync* instruction (see Book III-S, Section 5.9.2) in the preceding sequence, in conjunction with the *ld* instruction and the loop, ensure that all storage accesses associated with instructions preceding the *ptesync* instruction, and all Reference, and Change bit updates associated with additional address translations that were performed, by the thread executing the *ptesync* instruction, before the *ptesync* instruction is executed, have been performed with respect to all threads and mechanisms, to the extent required by the associated Memory Coherence Required attributes, before the thread enters power-saving mode. The *b* instruction (branch to self) is not executed since the preceding power-saving mode instruction puts the thread in a power-saving mode in which instructions are not executed. Even though it is not executed, requiring it to be present simplifies implementation and testing because it reduces the synchronization needed between execution of the instruction stream and entry into power-saving mode.

If the performance monitor is in use when the thread enters power-saving mode, the Performance Monitor data obtainable when the thread exits from power-saving mode may be incomplete or otherwise misleading.

Programming Note

Software is not required to set the RI bit to any particular value prior to entering power-saving mode because the setting of $SRR1_{62}$ upon exit from power-saving mode is independent of the value of the RI bit upon entry into power-saving mode.

Chapter 4. Fixed-Point Facility

4.1 Fixed-Point Facility Overview

This chapter describes the details concerning the registers and the privileged instructions implemented in the Fixed-Point Facility that are not covered in Book I.

4.2 Special Purpose Registers

Special Purpose Registers (SPRs) are read and written using the *mf spr* (page 764) and *mt spr* (page 763) instructions. Most SPRs are defined in other chapters of this book; see the index to locate those definitions.

4.3 Fixed-Point Facility Registers

4.3.1 Processor Version Register

The Processor Version Register (PVR) is a 32-bit read-only register that contains a value identifying the version and revision level of the implementation. The contents of the PVR can be copied to a GPR by the *mf spr* instruction. Read access to the PVR is privileged; write access is not provided.

Figure 7. Processor Version Register

The PVR distinguishes between implementations that differ in attributes that may affect software. It contains two fields.

Version A 16-bit number that identifies the version of the implementation. Different version numbers indicate major differences between implementations, such as which categories are supported.

Revision A 16-bit number that distinguishes between implementations of the version. Different revision numbers indicate minor differences between implementations having the same version number, such as clock rate and Engineering Change level.

Version numbers are assigned by the Power ISA process. Revision numbers are assigned by an implementation-defined process.

4.3.2 Processor Identification Register

The Processor Identification Register (PIR) is a 32-bit register that contains a value that can be used to distinguish the thread from other threads in the system. The contents of the PIR can be copied to a GPR by the *mf spr* instruction. Read access to the PIR is privileged; write access, if provided, is hypervisor privileged. It is

implementation-dependent whether write access is provided.

Bits	Name	Description
0:31	PROCID	Thread ID

Figure 8. Processor Identification Register

The means by which the PIR is initialized are implementation-dependent.

The PIR is a hypervisor resource; see Chapter 2.

4.3.3 Control Register

The Control Register (CTRL) is a 32-bit register that controls an external I/O pin. This signal may be used for the following:

- driving the RUN Light on a system operator panel
- Direct External exception routing
- Performance Monitor Counter incrementing (see Appendix B)

Bit	Name	Description
63	RUN	Run state bit

All other fields are implementation-dependent.

Figure 9. Control Register

The CTRL RUN can be used by the operating system to indicate when the thread is doing useful work.

The contents of the CTRL can be written by the *mtspr* instruction and read by the *mfspr* instruction. Write access to the CTRL is privileged. Reads can be performed in privileged or problem state.

4.3.4 Program Priority Register

Privileged programs may set a wider range of program priorities in the PRI field of PPR and PPR32 than may be set by problem-state programs (see Chapter 3 of Book II). Problem-state programs may only set values in the range of 0b010 to 0b100. Privileged programs may set values in the range of 0b001 to 0b110. Hypervisor software may also set 0b111. If a program attempts to set a value that is not available to it, the PRI field remains unchanged. The values and their corresponding meanings are as follows.

Bit(s)	Description
11:13	Program Priority (PRI)
001	very low
010	low
011	medium low (normal)
100	medium
101	medium high
110	high
111	very high

4.3.5 Software-use SPRs

Software-use SPRs are 64-bit registers provided for use by software.

Figure 10. Software-use SPRs

SPRG0, SPRG1, and SPRG2 are privileged registers. SPRG3 is a privileged register except that the contents may be copied to a GPR in Problem state when accessed using the *mf spr* instruction.

Programming Note

Neither the contents of the SPRGs, nor accessing them using *mt spr* or *mf spr*, has a side effect on the operation of the thread. One or more of the registers is likely to be needed by non-hypervisor interrupt handler programs (e.g., as scratch registers and/or pointers to per thread save areas).

Operating systems must ensure that no sensitive data are left in SPRG3 when a problem state program is dispatched, and operating systems for secure systems must ensure that SPRG3 cannot be used to implement a “covert channel” between problem state programs. These requirements can be satisfied by clearing SPRG3 before passing control to a program that will run in problem state.

HSPRG0 and HSPRG1 are 64-bit registers provided for use by hypervisor programs.

Figure 11. SPRs for use by hypervisor programs

Programming Note

Neither the contents of the HSPRGs, nor accessing them using *mt spr* or *mf spr*, has a side effect on the operation of the thread. One or more of the registers is likely to be needed by hypervisor interrupt handler programs (e.g., as scratch registers and/or pointers to per thread save areas).

4.4 Fixed-Point Facility Instructions

4.4.1 Fixed-Point Load and Store Caching Inhibited Instructions

The storage accesses caused by the instructions described in this section are performed as though the specified storage location is Caching Inhibited and Guarded. The instructions can be executed only in hypervisor state. If any of the following restrictions on execution of these instructions (while in hypervisor state) are violated, the results are undefined.

- They must be executed only when $MSR_{DR}=0$.
- The specified storage location must not be in storage specified by the Hypervisor Real Mode Storage Control facility to be treated as non-Guarded.
- Software must ensure that the specified storage location is not in the caches.

Programming Note

The instructions described in this section can be used to permit a control register on an I/O device to be accessed without permitting the corresponding storage location to be copied into the caches.

See also, in Book I, the introductions to Section 3.3.1, “Fixed-Point Storage Access Instructions”, Section 3.3.2, “Fixed-Point Load Instructions”, and Section 3.3.3, “Fixed-Point Store Instructions”.

Load Byte and Zero Caching Inhibited Indexed X-form

lbzcix RT,RA,RB

0	31	RT	RA	RB	853	/
	6	11	16	21		31

```

if RA = 0 then b ← 0
else          b ← (RA)
EA ← b + (RB)
RT ← 560 || MEM(EA, 1)

```

Let the effective address (EA) be the sum (RAI0)+(RB). The byte in storage addressed by EA is loaded into RT_{56:63}. RT_{0:55} are set to 0.

The storage access caused by this instruction is performed as though the specified storage location is Caching Inhibited and Guarded.

This instruction is hypervisor privileged.

Special Registers Altered:

None

Load Word and Zero Caching Inhibited Indexed X-form

lwzcix RT,RA,RB

0	31	RT	RA	RB	789	/
	6	11	16	21		31

```

if RA = 0 then b ← 0
else          b ← (RA)
EA ← b + (RB)
RT ← 320 || MEM(EA, 4)

```

Let the effective address (EA) be the sum (RAI0)+(RB). The word in storage addressed by EA is loaded into RT_{32:63}. RT_{0:31} are set to 0.

The storage access caused by this instruction is performed as though the specified storage location is Caching Inhibited and Guarded.

This instruction is hypervisor privileged.

Special Registers Altered:

None

Load Halfword and Zero Caching Inhibited Indexed X-form

lhzcix RT,RA,RB

0	31	RT	RA	RB	821	/
	6	11	16	21		31

```

if RA = 0 then b ← 0
else          b ← (RA)
EA ← b + (RB)
RT ← 480 || MEM(EA, 2)

```

Let the effective address (EA) be the sum (RAI0)+(RB). The halfword in storage addressed by EA is loaded into RT_{48:63}. RT_{0:47} are set to 0.

The storage access caused by this instruction is performed as though the specified storage location is Caching Inhibited and Guarded.

This instruction is hypervisor privileged.

Special Registers Altered:

None

Load Doubleword Caching Inhibited Indexed X-form

ldcix RT,RA,RB

0	31	RT	RA	RB	885	/
	6	11	16	21		31

```

if RA = 0 then b ← 0
else          b ← (RA)
EA ← b + (RB)
RT ← MEM(EA, 8)

```

Let the effective address (EA) be the sum (RAI0)+(RB). The doubleword in storage addressed by EA is loaded into RT.

The storage access caused by this instruction is performed as though the specified storage location is Caching Inhibited and Guarded.

This instruction is hypervisor privileged.

Special Registers Altered:

None

**Store Byte Caching Inhibited Indexed
X-form**

stbcix RS,RA,RB

31	RS	RA	RB	981	/

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
MEM(EA, 1) ← (RS)56:63

```

Let the effective address (EA) be the sum (RAI0)+(RB). (RS)_{56:63} are stored into the byte in storage addressed by EA.

The storage access caused by this instruction is performed as though the specified storage location is Caching Inhibited and Guarded.

This instruction is hypervisor privileged.

Special Registers Altered:

None

**Store Halfword Caching Inhibited Indexed
X-form**

sthcix RS,RA,RB

31	RS	RA	RB	949	/
0	6	11	16	21	31

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
MEM(EA, 2) ← (RS)48:63

```

Let the effective address (EA) be the sum (RAI0)+(RB). (RS)_{48:63} are stored into the halfword in storage addressed by EA.

The storage access caused by this instruction is performed as though the specified storage location is Caching Inhibited and Guarded.

This instruction is hypervisor privileged.

Special Registers Altered:

None

**Store Word Caching Inhibited Indexed
X-form**

stwcix RS,RA,RB

31	RS	RA	RB	917	/
0	6	11	16	21	31

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
MEM(EA, 4) ← (RS)32:63

```

Let the effective address (EA) be the sum (RAI0)+(RB). (RS)_{32:63} are stored into the word in storage addressed by EA.

The storage access caused by this instruction is performed as though the specified storage location is Caching Inhibited and Guarded.

This instruction is hypervisor privileged.

Special Registers Altered:

None

**Store Doubleword Caching Inhibited
Indexed
X-form**

stdcix RS,RA,RB

31	RS	RA	RB	1013	/
0	6	11	16	21	31

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
MEM(EA, 8) ← (RS)

```

Let the effective address (EA) be the sum (RAI0)+(RB). (RS) is stored into the doubleword in storage addressed by EA.

The storage access caused by this instruction is performed as though the specified storage location is Caching Inhibited and Guarded.

This instruction is hypervisor privileged.

Special Registers Altered:

None

4.4.2 Fixed-Point Load and Store Quadword Instructions [Category: Load/Store Quadword]

Load Quadword

DQ-form

lq RTp,DQ(RA)

56	RTp	RA	DQ	///
0	6	11	16	28 31

```
if RA = 0 then b ← 0
else            b ← (RA)
EA ← b + EXTS(DQ || 0b0000)
RTp ← MEM(EA, 8)
```

Let the effective address (EA) be the sum (RAI0)+ (DQ||0b0000). The quadword in storage addressed by EA is loaded into register pair RTp.

EA must be a multiple of 16. If it is not, an Alignment interrupt occurs.

If RTp is odd or RTp=RA, the instruction form is invalid. If RTp=RA, an attempt to execute this instruction causes an Illegal Instruction type Program interrupt. (The RTp=RA case includes the case of RTp=RA=0.)

This instruction is not supported in Little-Endian mode. Execution of this instruction in Little-Endian mode causes either an Alignment interrupt or the results are boundedly undefined.

This instruction is privileged.

Special Registers Altered:
None

Store Quadword

DS-form

stq RSp,DS(RA)

62	RSp	RA	DS	2
0	6	11	16	30 31

```
if RA = 0 then b ← 0
else            b ← (RA)
EA ← b + EXTS(DS || 0b00)
MEM(EA, 8) ← RSp
```

Let the effective address (EA) be the sum (RAI0)+ (DS||0b00). The contents of register pair RSp are stored into the quadword in storage addressed by EA.

EA must be a multiple of 16. If it is not, an Alignment interrupt occurs.

If RSp is odd, the instruction form is invalid.

This instruction is not supported in Little-Endian mode. Execution of this instruction in Little-Endian mode causes either an Alignment interrupt or the results are boundedly undefined.

This instruction is privileged.

Special Registers Altered:
None

4.4.3 OR Instruction

or Rx,Rx,Rx can be used to set PPR_{PRI} (see Section 4.3.4) as shown in Figure 12. PPR_{PRI} remains unchanged if the privilege state of the thread executing the instruction is lower than the privilege indicated in the figure. (The encodings available to problem-state programs, as well as encodings for additional shared resource hints not shown here, are described in Chapter 3 of Book II.)

Rx	PPR _{PRI}	Priority	Privileged
31	001	very low	yes
1	010	low	no
6	011	medium low	no
2	100	medium (normal)	no
5	101	medium high	yes
3	110	high	yes
7	111	very high	hypv

Figure 12. Priority levels for *or Rx,Rx,Rx*

4.4.4 Move To/From System Register Instructions

The *Move To Special Purpose Register* and *Move From Special Purpose Register* instructions are described in Book I, but only at the level available to an application programmer. For example, no mention is made there of registers that can be accessed only in privileged state. The descriptions of these instructions given below extend the descriptions given in Book I, but do not list Special Purpose Registers that are implementation-dependent. In the descriptions of these instructions given below, the “defined” SPR numbers are the SPR numbers shown in the figure for the instruction and the implementation-specific SPR numbers that are implemented, and similarly for “defined” registers.

Extended mnemonics

Extended mnemonics are provided for the *mtspr* and *mfspr* instructions so that they can be coded with the SPR name as part of the mnemonic rather than as a numeric operand. See Appendix A, “Assembler Extended Mnemonics” on page 867.

Figure 13. SPR encodings (Sheet 1 of 2)

Move To Special Purpose Register XFX-form

mtspr SPR,RS

0	31	RS	spr	467	/
	6	11	21	31	

```

n ← spr5:9 || spr0:4
if (n ≠ 13) & (n ≠ 29) & (n ≠ 157) & (n ≠ 336) then
  if length(SPR(n)) = 64 then
    SPR(n) ← (RS)
  else
    SPR(n) ← (RS)32:63
else
  if n = 13 then
    if MSRHV PR = 0b10 then
      SPR(13) ← (RS)
    else
      if MSRHV PR = 0b00 then
        SPR(13) ← ((RS) & AMOR) | ((SPR(13)) & ¬AMOR)
      else
        SPR(13) ← ((RS) & UAMOR) | ((SPR(13)) & ¬UAMOR)
  if n = 29 then
    if MSRHV PR = 0b10 then
      SPR(29) ← (RS)
    else
      SPR(29) ← ((RS) & AMOR) | ((SPR(29)) & ¬AMOR)
  if n = 157 then
    if MSRHV PR = 0b10 then
      SPR(157) ← (RS)
    else
      SPR(157) ← (RS) & AMOR
  if n = 336 then
    SPR(336) ← (SPR(336)) & (RS)

```

The SPR field denotes a Special Purpose Register, encoded as shown in Figure 13. The contents of register RS are placed into the designated Special Purpose Register, except as described in the next four paragraphs. For Special Purpose Registers that are 32 bits long, the low-order 32 bits of RS are placed into the SPR.

When the designated SPR is the Authority Mask Register (AMR), using SPR 13 or SPR 29, and MSR_{HV PR}=0b00, the contents of bit positions of register RS corresponding to 1 bits in the Authority Mask Override Register (AMOR) are placed into the corresponding bits of the AMR; the other AMR bits are not modified.

When the designated SPR is the AMR, using SPR 13, and MSR_{PR}=1, the contents of bit positions of register RS corresponding to 1 bits in the User Authority Mask Override Register (UAMOR) are placed into the corresponding bits of the AMR; the other AMR bits are not modified.

When the designated SPR is the UAMOR and MSR_{HV PR}=0b00, the contents of register RS are ANDed with the contents of the AMOR and the result is placed into the UAMOR.

When the designated SPR is the Hypervisor Maintenance Exception Register (HMER), the contents of register RS are ANDed with the contents of the HMER and the result is placed into the HMER.

For this instruction, SPRs TBL and TBU are treated as separate 32-bit registers; setting one leaves the other unaltered.

spr₀=1 if and only if writing the register is privileged. Execution of this instruction specifying an SPR number with spr₀=1 causes a Privileged Instruction type Program interrupt when MSR_{PR}=1 and, if the SPR is a hypervisor resource (see Figure 13), when MSR_{HV PR}=0b00.

Execution of this instruction specifying an SPR number that is not defined for the implementation, including SPR numbers that are shown in Figure 13 but are in a category that is not supported by the implementation, causes one of the following.

- if spr₀=0:
 - if MSR_{PR}=1: Hypervisor Emulation Assistance interrupt
 - if MSR_{PR}=0: Hypervisor Emulation Assistance interrupt for SPR 0 and no operation (i.e. the instruction is treated as a no-op) for all other SPRs
- if spr₀=1:
 - if MSR_{PR}=1: Privileged Instruction type Program interrupt
 - if MSR_{PR}=0: no operation (i.e. the instruction is treated as a no-op)

Special Registers Altered:

See Figure 13

Programming Note

For a discussion of software synchronization requirements when altering certain Special Purpose Registers, see Chapter 10. "Synchronization Requirements for Context Alterations" on page 861.

Move From Special Purpose Register XFX-form

mf spr RT, SPR

31	RT	spr	339	/
0	6	11	21	31

```

n ← spr5:9 || spr0:4
if length( SPR(n) ) = 64 then
  RT ← SPR(n)
else
  RT ← 320 || SPR(n)

```

The SPR field denotes a Special Purpose Register, encoded as shown in Figure 13. The contents of the designated Special Purpose Register are placed into register RT. For Special Purpose Registers that are 32 bits long, the low-order 32 bits of RT receive the contents of the Special Purpose Register and the high-order 32 bits of RT are set to zero.

spr₀=1 if and only if reading the register is privileged. Execution of this instruction specifying an SPR number with spr₀=1 causes a Privileged Instruction type Program interrupt when MSR_{PR}=1 and, if the SPR is a hypervisor resource (see Figure 13), when MSR_{HV PR}=0b00.

Execution of this instruction specifying an SPR number that is not defined for the implementation, including SPR numbers that are shown in Figure 13 but are in a category that is not supported by the implementation, causes one of the following.

- if spr₀=0:
 - if MSR_{PR}=1: Hypervisor Emulation Assistance interrupt
 - if MSR_{PR}=0: Hypervisor Emulation Assistance interrupt for SPRs 0, 4, 5, and 6 and no operation (i.e. the instruction is treated as a no-op) for all other SPRs
- if spr₀=1:
 - if MSR_{PR}=1: Privileged Instruction type Program interrupt
 - if MSR_{PR}=0: no operation (i.e. the instruction is treated as a no-op)

Special Registers Altered:

None

Note

See the Notes that appear with *mtspr*.

  MSR48 ← (RS)48 | (RS)49
  MSR58 ← (RS)58 | (RS)49
  MSR59 ← (RS)59 | (RS)49
  MSR32:47 49:50 52:57 60:62 ← (RS)32:47 49:50 52:57 60:62
else
  MSR48 62 ← (RS)48 62

```

The MSR is set based on the contents of register RS and of the L field.

L=0:

The result of ORing bits 48 and 49 of register RS is placed into MSR₄₈. The result of ORing bits 58 and 49 of register RS is placed into MSR₅₈. The result of ORing bits 59 and 49 of register RS is placed into MSR₅₉. Bits 32:47, 49:50, 52:57, and 60:62 of register RS are placed into the corresponding bits of the MSR.

L=1:

Bits 48 and 62 of register RS are placed into the corresponding bits of the MSR. The remaining bits of the MSR are unchanged.

This instruction is privileged.

If L=0 this instruction is context synchronizing. If L=1 this instruction is execution synchronizing; in addition, the alterations of the EE and RI bits take effect as soon as the instruction completes.

Special Registers Altered:

MSR

Except in the *mtmsr* instruction description in this section, references to “*mtmsr*” in this document imply either L value unless otherwise stated or obvious from context (e.g., a reference to an *mtmsr* instruction that modifies an MSR bit other than the EE or RI bit implies L=0).

Programming Note

If this instruction sets MSR_{PR} to 1, it also sets MSR_{EE}, MSR_{IR}, and MSR_{DR} to 1.

This instruction does not alter MSR_{ME} or MSR_{LE}. (This instruction does not alter MSR_{HV} because it does not alter any of the high-order 32 bits of the MSR.)

If the only MSR bits to be altered are MSR_{EE} RI, to obtain the best performance L=1 should be used.

Programming Note

If MSR_{EE}=0 and an External or Decrementer exception is pending, executing an *mtmsr* instruction that sets MSR_{EE} to 1 will cause the External or Decrementer interrupt to occur before the next instruction is executed, if no higher priority exception exists (see Section 6.8, “Interrupt Priorities” on page 845). Similarly, if a Hypervisor Decrementer interrupt is pending, execution of the instruction by the hypervisor causes a Hypervisor Decrementer interrupt to occur if HDICE=1.

For a discussion of software synchronization requirements when altering certain MSR bits, see Chapter 10.

Programming Note

mtmsr serves as both a basic and an extended mnemonic. The Assembler will recognize an *mtmsr* mnemonic with two operands as the basic form, and an *mtmsr* mnemonic with one operand as the extended form. In the extended form the L operand is omitted and assumed to be 0.

Programming Note

There is no need for an analogous version of the *mfmsr* instruction, because the existing instruction copies the entire contents of the MSR to the selected GPR.

Move To Machine State Register Doubleword X-form

mtmsrd RS,L

0	6	11	15	16	21	31	/

if L = 0 then

$MSR_{48} \leftarrow (RS)_{48} \mid (RS)_{49}$

$MSR_{58} \leftarrow (RS)_{58} \mid (RS)_{49}$

$MSR_{59} \leftarrow (RS)_{59} \mid (RS)_{49}$

$MSR_{0:2, 4:47, 49:50, 52:57, 60:62} \leftarrow (RS)_{0:2, 4:47, 49:50, 52:57, 60:62}$

else

$MSR_{48, 62} \leftarrow (RS)_{48, 62}$

The MSR is set based on the contents of register RS and of the L field.

L=0:

The result of ORing bits 48 and 49 of register RS is placed into MSR_{48} . The result of ORing bits 58 and 49 of register RS is placed into MSR_{58} . The result of ORing bits 59 and 49 of register RS is placed into MSR_{59} . Bits 0:2, 4:47, 49:50, 52:57, and 60:62 of register RS are placed into the corresponding bits of the MSR.

L=1:

Bits 48 and 62 of register RS are placed into the corresponding bits of the MSR. The remaining bits of the MSR are unchanged.

This instruction is privileged.

If L=0 this instruction is context synchronizing. If L=1 this instruction is execution synchronizing; in addition, the alterations of the EE and RI bits take effect as soon as the instruction completes.

Special Registers Altered:

MSR

Except in the *mtmsrd* instruction description in this section, references to "*mtmsrd*" in this document imply either L value unless otherwise stated or obvious from context (e.g., a reference to an *mtmsrd* instruction that modifies an MSR bit other than the EE or RI bit implies L=0).

Programming Note

If $MSR_{EE}=0$ and an External or Decrementer exception is pending, executing an *mtmsrd* instruction that sets MSR_{EE} to 1 will cause the External or Decrementer interrupt to occur before the next instruction is executed, if no higher priority exception exists (see Section 6.8, "Interrupt Priorities" on page 845). Similarly, if a Hypervisor Decrementer interrupt is pending, execution of the instruction by the hypervisor causes a Hypervisor Decrementer interrupt to occur if $HDICE=1$.

For a discussion of software synchronization requirements when altering certain MSR bits, see Chapter 10.

Programming Note

mtmsrd serves as both a basic and an extended mnemonic. The Assembler will recognize an *mtmsrd* mnemonic with two operands as the basic form, and an *mtmsrd* mnemonic with one operand as the extended form. In the extended form the L operand is omitted and assumed to be 0.

Programming Note

If this instruction sets MSR_{PR} to 1, it also sets MSR_{EE} , MSR_{IR} , and MSR_{DR} to 1.

This instruction does not alter MSR_{LE} , MSR_{ME} or MSR_{HV} .

If the only MSR bits to be altered are $MSR_{EE, RI}$, to obtain the best performance L=1 should be used.

5.1 Overview

A program references storage using the effective address computed by the hardware when it executes a *Load*, *Store*, *Branch*, or *Cache Management* instruction, or when it fetches the next sequential instruction. The effective address is translated to a real address according to procedures described in Section 5.7.3, in Section 5.7.5 and in the following sections. The real address is what is presented to the storage subsystem.

For a complete discussion of storage addressing and effective address calculation, see Section 1.10 of Book I.

5.2 Storage Exceptions

A *storage exception* results when the sequential execution model requires that a storage access be performed but the access is not permitted (e.g., is not permitted by the storage protection mechanism), the access cannot be performed because the effective address cannot be translated to a real address, or the access matches some tracking mechanism criteria (e.g., Data Address Breakpoint).

In certain cases a storage exception may result in the “restart” of (re-execution of at least part of) a *Load* or *Store* instruction. See Section 2.1 of Book II, and Section 6.6 in this Book.

5.3 Instruction Fetch

Instructions are fetched under control of MSR_{IR} .

$MSR_{IR}=0$

The effective address of the instruction is interpreted as described in Section 5.7.3.

$MSR_{IR}=1$

The effective address of the instruction is translated by the Address Translation mechanism described beginning in Section 5.7.5.

5.3.1 Implicit Branch

Explicitly altering certain MSR bits (using *mtmsr[d]*), or explicitly altering SLB entries, Page Table Entries, or certain System Registers (including the HRMOR, and possibly other implementation-dependent registers), may have the side effect of changing the addresses, effective or real, from which the current instruction stream is being fetched. This side effect is called an *implicit branch*. For example, an *mtmsrd* instruction that changes the value of MSR_{SF} may change the effective addresses from which the current instruction stream is being fetched. The MSR bits and System Registers (excluding implementation-dependent regis-

ters) for which alteration can cause an implicit branch are indicated as such in Chapter 10. “Synchronization Requirements for Context Alterations” on page 861. Implicit branches are not supported by the Power ISA. If an implicit branch occurs, the results are boundedly undefined.

5.3.2 Address Wrapping Combined with Changing MSR Bit SF

If the current instruction is at effective address $2^{32} - 4$ and is an *mtmsrd* instruction that changes the contents of MSR_{SF} , the effective address of the next sequential instruction is undefined.

Programming Note

In the case described in the preceding paragraph, if an interrupt occurs before the next sequential instruction is executed, the contents of $SRR0$, or $HSRR0$, as appropriate to the interrupt, are undefined.

5.4 Data Access

Data accesses are controlled by MSR_{DR} .

$MSR_{DR}=0$

The effective address of the data is interpreted as described in Section 5.7.3.

$MSR_{DR}=1$

The effective address of the data is translated by the Address Translation mechanism described in Section 5.7.5.

5.5 Performing Operations Out-of-Order

An operation is said to be performed “in-order” if, at the time that it is performed, it is known to be required by the sequential execution model. An operation is said to be performed “out-of-order” if, at the time that it is performed, it is not known to be required by the sequential execution model.

Operations are performed out-of-order on the expectation that the results will be needed by an instruction that will be required by the sequential execution model. Whether the results are really needed is contingent on everything that might divert the control flow away from the instruction, such as *Branch*, *Trap*, *System Call*, and *Return From Interrupt* instructions, and interrupts, and on everything that might change the context in which the instruction is executed.

Typically, operations are performed out-of-order when resources are available that would otherwise be idle, so

the operation incurs little or no cost. If subsequent events such as branches or interrupts indicate that the operation would not have been performed in the sequential execution model, any results of the operation are abandoned (except as described below).

In the remainder of this section, including its subsections, “*Load* instruction” includes the *Cache Management* and other instructions that are stated in the instruction descriptions to be “treated as a *Load*”, and similarly for “*Store* instruction”.

A data access that is performed out-of-order may correspond to an arbitrary *Load* or *Store* instruction (e.g., a *Load* or *Store* instruction that is not in the instruction stream being executed). Similarly, an instruction fetch that is performed out-of-order may be for an arbitrary instruction (e.g., the aligned word at an arbitrary location in instruction storage).

Most operations can be performed out-of-order, as long as the machine appears to follow the sequential execution model. Certain out-of-order operations are restricted, as follows.

- **Stores**
Stores are not performed out-of-order (even if the *Store* instructions that caused them were executed out-of-order).
- **Accessing Guarded Storage**
The restrictions for this case are given in Section 5.8.1.1.

The only permitted side effects of performing an operation out-of-order are the following.

- A Machine Check or Checkstop that could be caused by in-order execution may occur out-of-order, except as described in Section 5.7.3.3.1 for the Hypervisor Real Mode Storage Control facility.
- On implementations which support Reference and Change bits, these bits may be set as described in Section 5.7.8.
- Non-Guarded storage locations that could be fetched into a cache by in-order fetching or execution of an arbitrary instruction may be fetched out-of-order into that cache.

5.6 Invalid Real Address

A storage access (including an access that is performed out-of-order; see Section 5.5) may cause a Machine Check if the accessed storage location contains an uncorrectable error or does not exist.

In the case that the accessed storage location does not exist, the Checkstop state may be entered. See Section 6.5.2 on page 831.

Programming Note

In configurations supporting multiple partitions, hypervisor software must ensure that a storage access by a program in one partition will not cause a Checkstop or other system-wide event that could affect the integrity of other partitions (see Chapter 2). For example, such an event could occur if a real address placed in a Page Table Entry or made accessible to a partition using the Offset Real Mode Address mechanism (see Section 5.7.3.2) does not exist.

5.7 Storage Addressing

Storage Control Overview

- Real address space size is 2^m bytes, $m \leq 60$; see Note 1.
- Real page size is 2^{12} bytes (4 KB).
- Effective address space size is 2^{64} bytes.
- An effective address is translated to a virtual address via the Segment Lookaside Buffer (SLB).
 - Virtual address space size is 2^n bytes, $65 \leq n \leq 78$; see Note 2.
 - Segment size is 2^s bytes, $s=28$ or 40 .
 - $2^{n-40} \leq$ number of virtual segments $\leq 2^{n-28}$; see Note 2.
 - Virtual page size is 2^p bytes, where $12 \leq p$, and 2^p is no larger than either the size of the biggest segment or the real address space; a size of 4 KB, 64 KB, and an implementation-dependent number of other sizes are supported; see Note 3. The Page Table specifies the virtual page size. The SLB specifies the base virtual page size, which is the smallest virtual page size that the segment can contain. The base virtual page size is 2^p bytes.
 - Segments contain pages of a single size, a mixture of 4 KB and 64 KB pages, or a mixture of page sizes that include implementation-dependent page sizes.
- A virtual address is translated to a real address via the Page Table.
 - Virtual page size is 2^p bytes, where $12 \leq p$, and 2^p is no larger than either the size of the biggest segment or the real address space; a size of 4KB, 64 KB, and an implementation-dependent number of other sizes are supported; see Note 3.

Notes:

1. The value of m is implementation-dependent (subject to the maximum given above). When used to address storage, the high-order $60-m$ bits of the “60-bit” real address must be zeros.
2. The value of n is implementation-dependent (subject to the range given above). In references to 78-bit virtual addresses elsewhere in this Book, the high-order $78-n$ bits of the “78-bit” virtual address are assumed to be zeros.
3. The supported values of p for the larger virtual page sizes are implementation-dependent (subject to the limitations given above).

5.7.1 32-Bit Mode

The computation of the 64-bit effective address is independent of whether the thread is in 32-bit mode or 64-

bit mode. In 32-bit mode ($MSR_{SF}=0$), the high-order 32 bits of the 64-bit effective address are treated as zeros for the purpose of addressing storage. This applies to both data accesses and instruction fetches. It applies independent of whether address translation is enabled or disabled. This truncation of the effective address is the only respect in which storage accesses in 32-bit mode differ from those in 64-bit mode.

Programming Note

Treating the high-order 32 bits of the effective address as zeros effectively truncates the 64-bit effective address to a 32-bit effective address such as would have been generated on a 32-bit implementation of the Power ISA. Thus, for example, the ESID in 32-bit mode is the high-order four bits of this truncated effective address; the ESID thus lies in the range 0-15. When address translation is enabled, these four bits would select a Segment Register on a 32-bit implementation of the Power ISA. The SLB entries that translate these 16 ESIDs can be used to emulate these Segment Registers.

5.7.2 Virtualized Partition Memory (VPM) Mode

VPM mode enables the hypervisor to reassign all or part of a partition’s memory transparently so that the reassignment is not visible to the partition. When this is done, the partition’s memory is said to be “virtualized.” The VPM field in the LPCR enables VPM mode separately when address translation is enabled and when translation is disabled.

If the thread is not in hypervisor state, and either address translation is enabled and $VPM_1=1$, or address translation is disabled and $VPM_0=1$, conditions that would have caused a Data Storage or an Instruction Storage interrupt if the affected memory were not virtualized instead cause a Hypervisor Data Storage or a Hypervisor Instruction Storage interrupt respectively. Because the Hypervisor Data Storage and Hypervisor Instruction Storage interrupts always put the thread in hypervisor state, they permit the hypervisor to handle the condition if appropriate (e.g., to restore the contents of a page that was reassigned), and to reflect it to the operating system’s Data Storage or Instruction Storage interrupt handler otherwise.

When address translation is enabled, VPM mode has no effect on address translation. When address translation is disabled, addressing is controlled as specified in Section 5.7.3.

5.7.3 Real And Virtual Real Addressing Modes

When a storage access is an instruction fetch performed when instruction address translation is disabled, or if the access is a data access and data address translation is disabled, it is said to be performed in “real addressing mode” if $VPM_0=0$ and the thread is not in hypervisor state. If the thread is in hypervisor state, the access is said to be performed in “hypervisor real addressing mode” regardless of the value of VPM_0 . If the thread is not in hypervisor state and $VPM_0=1$, the access is said to be performed in “virtual real addressing mode.” Storage accesses in real, hypervisor real, and virtual real addressing modes are performed in a manner that depends on the contents of MSR_{HV} , $LPES$, VPM , $VRMASD$, $HRMOR$, $RMLS$, $RMOR$ (see Chapter 2), bit 0 of the effective address (EA0), and the state of the Real Mode Storage Control Facility as described below. Bits 1:3 of the effective address are ignored.

$MSR_{HV}=1$

- If $EA_0=0$, the Hypervisor Offset Real Mode Address mechanism, described in Section 5.7.3.1, controls the access.
- If $EA_0=1$, bits 4:63 of the effective address are used as the real address for the access.

$MSR_{HV}=0$

- If $LPES_1=0$, the access causes a storage exception as described in Section 5.7.9.3.
- If $LPES_1=1$ and $VPM_0=0$, the Offset Real Mode Address mechanism, described in Section 5.7.3.2, controls the access.
- If $LPES_1=1$ and $VPM_0=1$, the Virtual Real Mode Addressing mechanism, described in Section 5.7.3.4, controls the access.

5.7.3.1 Hypervisor Offset Real Mode Address

If $MSR_{HV} = 1$ and $EA_0 = 0$, the access is controlled by the contents of the Hypervisor Real Mode Offset Register, as follows.

Hypervisor Real Mode Offset Register (HRMOR)

Bits 4:63 of the effective address for the access are ORed with the 60-bit offset represented by the contents of the HRMOR, and the 60-bit result is used as the real address for the access. The supported offset values are all values of the form $i \times 2^j$, where $0 \leq i < 2^k$, and j and r are implementation-dependent values having the properties that $12 \leq r \leq 26$ (i.e., the minimum offset granularity is 4 KB and the maximum offset granularity is 64 MB) and

$j+r = m$, where the real address size supported by the implementation is m bits.

Programming Note

$EA_{4:63-r}$ should equal $60-r$ 0. If this condition is satisfied, ORing the effective address with the offset produces a result that is equivalent to adding the effective address and the offset.

If $m < 60$, $EA_{4:63-m}$ and $HRMOR_{4:63-m}$ must be zeros.

5.7.3.2 Offset Real Mode Address

If $VPM_0=0$, $MSR_{HV}=0$, and $LPES_1=1$, the access is controlled by the contents of the Real Mode Limit Selector and Real Mode Offset Register, as specified below, and the set of storage locations accessible by code is referred to as the Real Mode Area (RMA).

Real Mode Limit Selector (RMLS)

If bits 4:63 of the effective address for the access are greater than or equal to the value (limit) represented by the contents of the $LPCR_{RMLS}$, the access causes a storage exception (see Section 5.7.9.3). In this comparison, if $m < 60$, bits 4:63- m of the effective address may be ignored (i.e., treated as if they were zeros), where the real address size supported by the implementation is m bits. The supported limit values are of the form 2^j , where $12 \leq j \leq 60$. Subject to the preceding sentence, the number and values of the limits supported are implementation-dependent.

Real Mode Offset Register (RMOR)

If the access is permitted by the $LPCR_{RMLS}$, bits 4:63 of the effective address for the access are ORed with the 60-bit offset represented by the contents of the RMOR, and the low-order m bits of the 60-bit result are used as the real address for the access. The supported offset values are all values of the form $i \times 2^s$, where $0 \leq i < 2^k$, and k and s are implementation-dependent values having the properties that 2^s is the minimum limit value supported by the implementation (i.e., the minimum value representable by the contents of the $LPCR_{RMLS}$) and $k+s = m$.

Programming Note

The offset specified by the RMOR should be a non-zero multiple of the limit specified by the RMLS. If these registers are set thus, ORing the effective address with the offset produces a result that is equivalent to adding the effective address and the offset. (The offset must not be zero, because real page 0 contains the fixed interrupt vectors and real pages 1 and 2 may be used for implementation-specific purposes; see Section 5.7.4, "Address Ranges Having Defined Uses" on page 777.)

5.7.3.3 Storage Control Attributes for Accesses in Real and Hypervisor Real Addressing Modes

Storage accesses in hypervisor real addressing mode are performed as though all of storage had the following storage control attributes, except as modified by the Hypervisor Real Mode Storage Control facility (see Section 5.7.3.3.1). (The storage control attributes are defined in Book II.)

- not Write Through Required
- not Caching Inhibited, for instruction fetches
- not Caching Inhibited, for data accesses except those caused by the *Load/Store Caching Inhibited* instructions; Caching Inhibited, for data accesses caused by the *Load/Store Caching Inhibited* instructions
- Memory Coherence Required, for data accesses
- Guarded
- not SAO

Storage accesses in real addressing mode are performed as though all of storage had the following storage control attributes. (Such accesses use the Offset Real Mode Address mechanism.)

- not Write Through Required
- not Caching Inhibited
- Memory Coherence Required, for data accesses
- not Guarded
- not SAO

Additionally, storage accesses in real or hypervisor real addressing modes are performed as though all storage was not No-execute.

Programming Note

Because storage accesses in real addressing mode and hypervisor real addressing mode do not use the SLB or the Page Table, accesses in these modes bypass all checking and recording of information contained therein (e.g., storage protection checks that use information contained therein are not performed, and reference and change information is not recorded).

5.7.3.3.1 Hypervisor Real Mode Storage Control

The Hypervisor Real Mode Storage Control facility provides a means of specifying portions of real storage that are treated as non-Guarded in hypervisor real addressing mode ($MSR_{HV_PR}=0b10$, and $MSR_{IR}=0$ or $MSR_{DR}=0$, as appropriate for the type of access). The remaining portions are treated as Guarded in hypervisor real addressing mode. The means is a hypervisor resource (see Chapter 2), and may also be system-specific.

Implementations may use the first, or both, of two techniques to specify portions of real storage that are treated as non-Guarded in hypervisor real addressing mode. For the first technique, the facility provides for the specification, at coarse granularity, of the boundary between non-Guarded and Guarded real storage. Any storage location below the specified boundary is treated as non-Guarded in hypervisor real addressing mode, and any storage location at or above the boundary is treated as Guarded in hypervisor real addressing mode. For the second technique, which cannot be applied to instruction storage, the facility divides real storage into history blocks, in implementation-specific sizes. If there is no history for a block and it is accessed using a *Load/Store Caching Inhibited* instruction, the access is performed as though the block is Guarded, and the block is treated as Guarded for subsequent accesses on a best effort basis, limited by the amount of history that the facility can maintain. If there is no history for a block and it is accessed using any other *Load* or *Store* instruction, the access is performed as though the block is Guarded, but the block is treated as non-Guarded for subsequent accesses on a best effort basis, limited by the amount of history that the facility can maintain.

The storage location specified by a *Load/Store Caching Inhibited* instruction must not be in storage that is specified by the Hypervisor Real Mode Storage Control facility to be treated as non-Guarded. If the second technique is used, the storage location specified by any other *Load* or *Store* instruction must not be in storage that is specified by the Hypervisor Real Mode Storage Control facility to be treated as Guarded. (For the second technique, "specified by the Hypervisor Real Mode Storage Control facility" means "specified in a history block".) For the second technique, the history can be erased using an *slbia* instruction; see Section 5.9.3.1.

The facility does not apply to implicit accesses to the Page Table performed during address translation or in recording reference and change information. These accesses are performed as described in Section 5.7.3.5.

Programming Note

The preceding capability can be used to improve the performance of hypervisor software that runs in hypervisor real addressing mode, by causing accesses to instructions and data that occupy well-behaved storage to be treated as non-Guarded.

5.7.3.4 Virtual Real Mode Addressing Mechanism

If $VPM_0=1$, $MSR_{HV}=0$, $LPES_1=1$, and $MSR_{DR}=0$ or $MSR_{IR}=0$ as appropriate for the type of access, the access is said to be made in virtual real addressing mode and is controlled by the mechanism specified below. The set of storage locations accessible by code is referred to as the Virtualized Real Mode Area (VRMA).

In virtual real addressing mode, address translation, storage protection, and reference and change recording are handled as follows.

- Address translation and storage protection are handled as if address translation were enabled, except that translation of effective addresses to virtual addresses use the SLBE values in Figure 14 instead of the entry in the SLB corresponding to the ESID. In this translation, bits 0:23 of the effective address are ignored (i.e. treated as if they were 0s), bits 24:63-m may be ignored if $m < 40$, and the Virtual Page Class Key Protection mechanism does not apply.

Programming Note

The Virtual Page Class Key Protection mechanism does not apply because the authority mask that an OS has set for application programs executing with address translation enabled may not be the same as the authority mask required by the OS when address translation is disabled, such as when first entering an interrupt handler.

- Reference and change recording are handled as if address translation were enabled.

Field	Value
ESID	³⁶ 0
V	1
B	0b01 - 1 TB
VSID	0b00 0x0_01FF_FFFF
K_s	0
K_p	undefined

Figure 14. SLBE for VRMA

Programming Note

The C bit in Figure 14 is set to 0 because the implementation-dependent lookaside information associated with the VRMA is expected to be long-lived. See Section 5.9.3.1.

Programming Note

The 1 TB VSID 0x0_01FF_FFFF should not be used by the operating system for purposes other than mapping the VRMA when address translation is enabled.

Programming Note

Software should specify $PTE_B = 0b01$ for all Page Table Entries that map the VRMA in order to be consistent with the values in Figure 14.

Programming Note

All accesses to the RMA are considered not Guarded. The G bit of the associated Page Table Entry determines whether an access to the VRMA is Guarded. Therefore, if an instruction is fetched from the VRMA, a Hypervisor Instruction Storage interrupt will result if $G=1$ in the associated Page Table Entry.

Programming Note

The RMA is considered non-SAO storage. However, any page in the VRMA is treated as SAO storage if $WIMG = 0b1110$ in the associated Page Table Entry.

5.7.3.5 Storage Control Attributes for Implicit Storage Accesses

Implicit accesses to the Page Table during address translation and in recording reference and change information are performed as though the storage occupied by the Page Table had the following storage control attributes.

- not Write Through Required
- not Caching Inhibited
- Memory Coherence Required
- not Guarded
- not SAO

The definition of “performed” given in Book II applies also to these implicit accesses; accesses for performing address translation are considered to be loads in this respect, and accesses for recording reference and change information are considered to be stores. These implicit accesses are ordered by the *ptesync* instruction as described in Section 5.9.2.

5.7.5 Address Translation Overview

The effective address (EA) is the address generated by the hardware for an instruction fetch or for a data access. If address translation is enabled, this address is passed to the Address Translation mechanism, which attempts to convert the address to a real address which is then used to access storage.

The first step in address translation is to convert the effective address to a virtual address (VA), as described in Section 5.7.6. The second step, conversion of the virtual address to a real address (RA), is described in Section 5.7.7.

If the effective address cannot be translated, a storage exception (see Section 5.2) occurs.

Figure 15 gives an overview of the address translation process.

5.7.4 Address Ranges Having Defined Uses

The address ranges described below have uses that are defined by the architecture.

- Fixed interrupt vectors

Except for the first 256 bytes, which are reserved for software use, the real page beginning at real address 0x0000_0000_0000_0000 is either used for interrupt vectors or reserved for future interrupt vectors.

- Implementation-specific use

The two contiguous real pages beginning at real address 0x0000_0000_0000_1000 are reserved for implementation-specific purposes.

- Offset Real Mode interrupt vectors

The real pages beginning at the real address specified by the HRMOR and RMOR are used similarly to the page for the fixed interrupt vectors.

- Page Table

A contiguous sequence of real pages beginning at the real address specified by SDR1 contains the Page Table.

Figure 15. Address translation overview

5.7.6 Virtual Address Generation

Conversion of a 64-bit effective address to a virtual address is done by searching the Segment Lookaside Buffer (SLB) as shown in Figure 16.

Figure 16. Translation of 64-bit effective address to 78 bit virtual address

5.7.6.1 Segment Lookaside Buffer (SLB)

The Segment Lookaside Buffer (SLB) specifies the mapping between Effective Segment IDs (ESIDs) and Virtual Segment IDs (VSIDs). The number of SLB entries is implementation-dependent, except that all implementations provide at least 32 entries.

The contents of the SLB are managed by software, using the instructions described in Section 5.9.3.1. See Chapter 10, "Synchronization Requirements for Context Alterations" on page 861 for the rules that software must follow when updating the SLB.

SLB Entry

Each SLB entry (SLBE, sometimes referred to as a "segment descriptor") maps one ESID to one VSID. Figure 17 shows the layout of an SLB entry

ESID	V	B	VSID	K_s	K_p	NLC	/	LP
0	36	37	39	89	94	95	96	

Bit(s)	Name	Description
0:35	ESID	Effective Segment ID
36	V	Entry valid (V=1) or invalid (V=0)
37:38	B	Segment Size Selector 0b00 - 256 MB (s=28) 0b01 - 1 TB (s=40) 0b10 - reserved 0b11 - reserved
39:88	VSID	Virtual Segment ID
89	K_s	Supervisor (privileged) state storage key (see Section 5.7.9.2)
90	K_p	Problem state storage key (See Section 5.7.9.2.)
91	N	No-execute segment if N=1
92	L	Virtual page size selector bit 0
93	C	Class
95:96	LP	Virtual page size selector bits 1:2

All other fields are reserved. B_0 (SLBE₃₇) is treated as a reserved field.

Figure 17. SLB Entry

Instructions cannot be executed from a No-execute (N=1) segment.

Segments may contain a mixture of pages sizes. The L and LP bits specify the base virtual page size that the segment may contain. The SLB_{LILP} encoding are those shown in Figure 18. The base virtual page size (also referred to as the “base page size”) is the smallest virtual page size for the segment. The base virtual page size is 2^b bytes. The actual virtual page size (also referred to as the “actual page size” or “virtual page size”) is specified by PTE_{L LP}.

encoding	page size
0b000	4 KB
0b101	64 KB
additional values ¹	2^b bytes, where $b > 12$ and b may differ among encoding values
¹ The “additional values” are implementation-dependent, as are the corresponding base virtual page sizes. Any values that are not supported by a given implementation are reserved in that implementation.	

Figure 18. Page Size Encoding

For each SLB entry, software must ensure the following requirements are satisfied.

- LILP contains a value supported by the implementation.
- The base virtual page size selected by the L and LP fields does not exceed the segment size selected by the B field.
- If s=40, the following bits of the SLB entry contain 0s.
 - ESID_{24:35}
 - VSID_{38:49}

The bits in the above two items are ignored by the hardware.

The Class field of the SLBE is used in conjunction with the *slbie* and *slbia* instructions (see Section 5.9.3.1). “Class” refers to a grouping of SLB entries and implementation-specific lookaside information so that only entries in a certain group need be invalidated and others might be preserved. The Class value assigned to an implementation-specific lookaside entry derived from an SLB entry must match the Class value of that SLB entry. The Class value assigned to an implementation-specific lookaside entry that is not derived from an SLB entry (such as real mode address “translations”) is 0.

Software must ensure that the SLB contains at most one entry that translates a given effective address, and that if the SLB contains an entry that translates a given effective address, then any previously existing translation of that effective address has been invalidated. An attempt to create an SLB entry that violates this requirement may cause a Machine Check.

Programming Note

It is permissible for software to replace the contents of a valid SLB entry without invalidating the translation specified by that entry provided the specified restrictions are followed. See Chapter 10 Note 11.

5.7.6.2 SLB Search

When the hardware searches the SLB, all entries are tested for a match with the EA. For a match to exist, the following conditions must be satisfied for indicated fields in the SLBE.

- V=1
- ESID_{0:63-s}=EA_{0:63-s}, where the value of s is specified by the B field in the SLBE being tested

If no match is found, the search fails. If one match is found, the search succeeds. If more than one match is found, one of the matching entries is used as if it were the only matching entry, or a Machine Check occurs.

If the SLB search succeeds, the virtual address (VA) is formed from the EA and the matching SLB entry fields as follows.

$$VA = VSID_{0:77-s} \parallel EA_{64-s:63}$$

The Virtual Page Number (VPN) is bits 0:77-p of the virtual address. The value of p is the actual virtual page size specified by the PTE used to translate the virtual address (see Section 5.7.7.1). If $SLBE_N = 1$, the N (No-execute) value used for the storage access is 1.

If the SLB search fails, a *segment fault* occurs. This is an Instruction Segment exception or a Data Segment exception, depending on whether the effective address is for an instruction fetch or for a data access.

5.7.7 Virtual to Real Translation

Conversion of a 78-bit virtual address to a real address is done by searching the Page Table as shown in Figure 19.

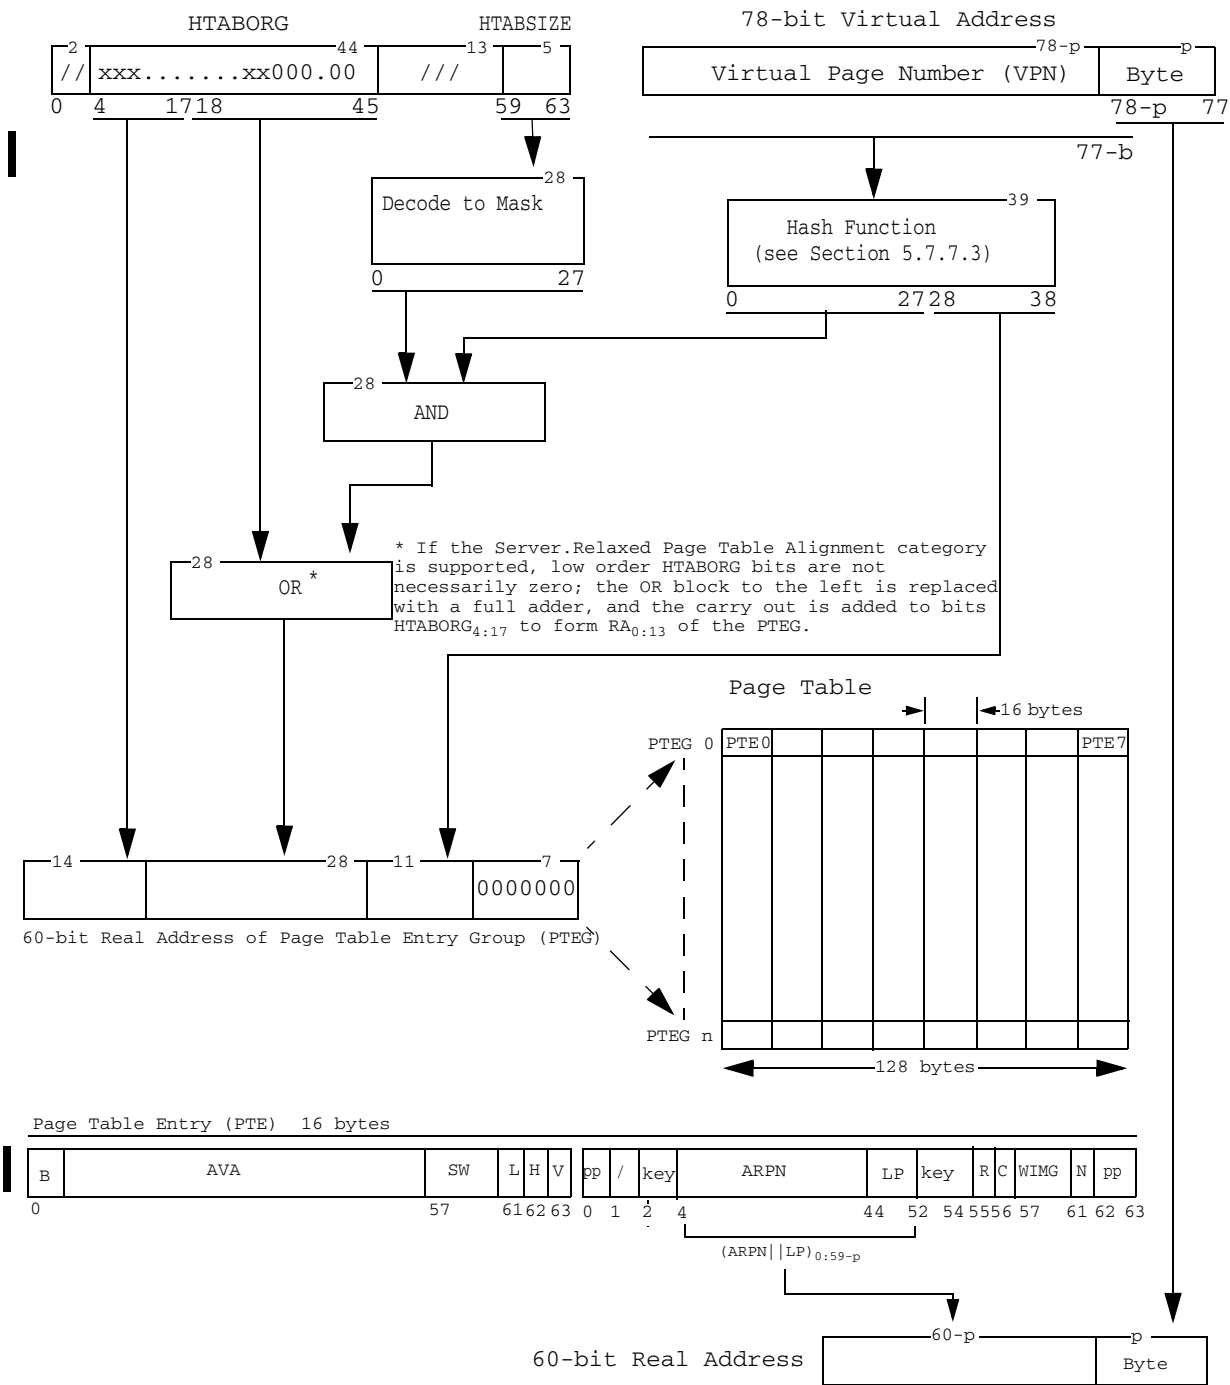

Figure 19. Translation of 78-bit virtual address to 60-bit real address

5.7.7.1 Page Table

The Hashed Page Table (HTAB) is a variable-sized data structure that specifies the mapping between virtual page numbers and real page numbers, where the real page number of a real page is bits 0:47 of the address of the first byte in the real page. The HTAB's size can be any size 2^n bytes where $18 \leq n \leq 46$. The HTAB must be located in storage having the storage control attributes that are used for implicit accesses to it (see Section 5.7.3.5). The starting address must be a multiple of its size unless the implementation supports the Server-Relaxed Page Table Alignment category, in which case its starting address is a multiple of 2^{18} bytes (see Section 5.7.7.4).

The HTAB contains Page Table Entry Groups (PTEGs). A PTEG contains 8 Page Table Entries (PTEs) of 16 bytes each; each PTEG is thus 128 bytes long. PTEGs are entry points for searches of the Page Table.

See Section 5.10 for the rules that software must follow when updating the Page Table.

Programming Note

The Page Table must be treated as a hypervisor resource (see Chapter 2), and therefore must be placed in real storage to which only the hypervisor has write access. Moreover, the contents of the Page Table must be such that non-hypervisor software cannot modify storage that contains hypervisor programs or data.

Page Table Entry

Each Page Table Entry (PTE) maps one VPN to one RPN. Figure 20 shows the layout of a PTE. This layout is independent of the Endian mode of the thread.

Dword	Bit(s)	Name	Description
0	0:1	B	Segment Size 0b00 - 256 MB 0b01 - 1 TB 0b10 - reserved 0b11 - reserved
	2:56	AVA	Abbreviated Virtual Address
	57:60	SW	Available for software use
	61	L	Virtual page size 0b0 - 4 KB 0b1 - greater than 4KB (large page)
	62	H	Hash function identifier
	63	V	Entry valid (V=1) or invalid (V=0)

Dword	Bit(s)	Name	Description
1	0	pp	Page Protection bit 0
	2:3	key	KEY bits 0:1
	4:43	ARNP	Abbreviated Real Page Number
	44:51	LP	Large page size selector
	52:54	key	KEY bits 2:4
	55	R	Reference bit
	56	C	Change bit
	57:60	WIMG	Storage control bits
	61	N	No-execute page if N=1
	62:63	pp	Page Protection bits 1:2

All other fields are reserved.

Figure 20. Page Table Entry

Programming Note

The H bit in the Page Table entry should not be set to one unless the secondary Page Table search has been enabled.

If $b \leq 23$, the Abbreviated Virtual Address (AVA) field contains bits 0:54 of the VA. Otherwise bits 0:77-b of the AVA field contain bits 0:77-b of the VA, and bits 78-b:54 of the AVA field must be zero.

Programming Note

The AVA field omits the low-order 23 bits of the VA. These bits are not needed in the PTE, because the low-order b of these bits are part of the byte offset into the virtual page and, if $b < 23$, the high-order 23-b of these bits are always used in selecting the PTEGs to be searched (see Section 5.7.7.3).

On implementations that support a virtual address size of only n bits, $n < 78$, bits 0:77-n of the AVA field must be zeros.

A virtual page is mapped to a sequence of 2^{p-12} contiguous real pages such that the low-order p-12 bits of the real page number of the first real page in the sequence are 0s.

$PTE_{L,LP}$ specify both a base virtual page size (henceforth referred to as the “base page size”) and an actual virtual page size (henceforth referred to as the “actual page size” or “virtual page size”). The actual page size is the size of the virtual page mapped by the PTE. The base page size is the smallest actual page size that a segment can contain. See Section 5.7.6.

If $PTE_L=0$, the base virtual page size and actual virtual page size are 4KB, and ARPN concatenated with LP (ARNPILP) contains the page number of the real page that maps the virtual page described by the entry.

If $PTE_L=1$, the base page size and actual page size are specified by $PTE_{L,P}$. In this case, the contents of $PTE_{L,P}$ have the format shown in Figure 21. Bits labelled “r” are

bits of the real page number. Bits labelled “z” specify the base page size and actual page size. The values of the “z” bits used to specify each size are implementation-dependent. The values of the “z” bits used to specify each size, along with all possible values of “r” bits in the LP field, must result in LP values distinct from other LP values for other sizes. Actual page sizes 4KB and 64KB are always supported; other actual page sizes are implementation-dependent. If $PTE_L=1$, the actual page size must be greater than 4 KB. Which combinations of different base page size and actual page size are supported is implementation-dependent, except that the combination of a base page size of 4 KB with an actual page size of 64 KB is always supported.

PTE _{LP}	actual page size
rrrr_rrrz	≥8 KB
rrrr_rrzz	≥16 KB
rrrr_rzzz	≥32 KB
rrrr_zzzz	≥64 KB
rrrz_zzzz	≥128 KB
rrzz_zzzz	≥256 KB
rzzz_zzzz	≥512 KB
zzzz_zzzz	≥1 MB

Figure 21. Format of PTE_{LP} when PTE_L=1

There are at least 2 formats of PTE_{LP} that specify a 64 KB page. One format is used with SLBE_{LILP} = 0b000 and one format is used with SLBE_{LILP} = 0b101.

The actual page size selected by the LP field must not exceed the segment size selected by the B field. Forms of PTE_{LP} not supported by a given implementation are treated as reserved values for that implementation.

The concatenation of the ARPN field and bits labeled “r” in the LP field contain the high-order bits of the real page number of the real page that maps the first 4KB of the virtual page described by the entry.

The low-order p-12 bits of the real page number contained in the ARPN and LP fields must be 0s and are ignored by the hardware.

Programming Note

The actual page size specified by a given PTE_{LP} format is at least $2^{12+(8-c)}$, where c is the number of r bits in the format.

Programming Note

Implementations often have implementation-dependent lookaside buffers (e.g. TLBs and ERATs) used to cache translations of recently used storage addresses. Mapping virtual storage to large pages may increase the effectiveness of such lookaside buffers, improving performance, because it is possible for such buffers to translate a larger range of addresses, reducing the frequency that the Page Table must be searched to translate an address.

Instructions cannot be executed from a No-execute (N=1) page.

Page Table Size

The number of entries in the Page Table directly affects performance because it influences the hit ratio in the Page Table and thus the rate of page faults. If the table is too small, it is possible that not all the virtual pages that actually have real pages assigned can be mapped via the Page Table. This can happen if too many hash collisions occur and there are more than 16 entries for the same primary/secondary pair of PTEGs (when the secondary Page Table search is enabled) or more than 8 entries for the same primary PTEG (when the secondary Page Table search is disabled).

While this situation cannot be guaranteed not to occur for any size Page Table, making the Page Table larger than the minimum size (see Section 5.7.7.2) will reduce the frequency of occurrence of such collisions.

Programming Note

If large pages are not used, it is recommended that the number of PTEGs in the Page Table be at least half the number of real pages to be accessed. For example, if the amount of real storage to be accessed is 2^{31} bytes (2 GB), then we have $2^{31-12}=2^{19}$ real pages. The minimum recommended Page Table size would be 2^{18} PTEGs, or 2^{25} bytes (32 MB).

5.7.7.2 Storage Description Register 1

The Storage Description Register 1 (SDR1) register is shown in Figure 22.

//	HTABORG	///	HTABSIZE
0	4	46	59 63

Bits	Name	Description
4:45	HTABORG	Real address of Page Table
59:63	HTABSIZE	Encoded size of Page Table

All other fields are reserved.

Figure 22. SDR1

SDR1 is a hypervisor resource; see Chapter 2.

The HTABORG field in SDR1 contains the high-order 42 bits of the 60-bit real address of the Page Table. The Page Table is thus constrained to lie on a 2^{18} byte (256 KB) boundary at a minimum. At least 11 bits from the hash function (see Figure 19) are used to index into the Page Table. The minimum size Page Table is 256 KB (2^{11} PTEGs of 128 bytes each).

The Page Table can be any size 2^n bytes where $18 \leq n \leq 46$. As the table size is increased, more bits are used from the hash to index into the table and the value in HTABORG must have more of its low-order bits equal to 0 unless the implementation supports the Server.Relaxed Page Table Alignment category; see Section 5.7.7.4.

The HTABSIZE field in SDR1 contains an integer giving the number of bits (in addition to the minimum of 11 bits) from the hash that are used in the Page Table index. This number must not exceed 28. HTABSIZE is used to generate a mask of the form 0b00...011...1, which is a string of 28 - HTABSIZE 0-bits followed by a string of HTABSIZE 1-bits. The 1-bits determine which additional bits (beyond the minimum of 11) from the hash are used in the index (see Figure 19). The number of low-order 0 bits in HTABORG must be greater than or equal to the value in HTABSIZE.

On implementations that support a real address size of only m bits, $m < 60$, bits 0:59- m of the HTABORG field are treated as reserved bits, and software must set them to zeros.

Programming Note

Let n equal the virtual address size (in bits) supported by the implementation. If $n < 67$, software should set the HTABSIZE field to a value that does not exceed $n-39$. Because the high-order 78- n bits of the VSID are assumed to be zeros, the hash value used in the Page Table search will have the high-order 67- n bits either all 0s (primary hash; see Section 5.7.7.3) or all 1s (secondary hash). If $HTABSIZE > n-39$, some of these hash value bits will be used to index into the Page Table, with the result that certain PTEGs will not be searched.

Example:

Suppose that the Page Table is 16,384 (2^{14}) 128-byte PTEGs, for a total size of 2^{21} bytes (2 MB). A 14-bit index is required. Eleven bits are provided from the hash to start with, so 3 additional bits from the hash must be selected. Thus the value in HTABSIZE must be 3 and the value in HTABORG must have its low-order 3 bits (bits 43:45 of SDR1) equal to 0. This means that the Page Table must begin on a $2^{3+11+7} = 2^{21} = 2$ MB boundary.

5.7.7.3 Page Table Search

When the hardware searches the Page Table, the accesses are performed as described in Section 5.7.3.5.

An outline of the HTAB search process is shown in Figure 19. If the implementation supports the Server.Relaxed Page Table Alignment category see Section 5.7.7.4. Up to two hash functions are used to

locate a PTE that may translate the given virtual address.

1. A 39-bit hash value is computed from the VA. The value of s is the value specified in the SLBE that was used to generate the virtual address; the value of b is equal to $\log_2(\text{base page size specified in the SLBE that was used to translate the address})$. **Primary Hash:**

If $s=28$, the hash value is computed by Exclusive ORing $VA_{11:49}$ with $(^{11+b}0IIVA_{50:77-b})$

If $s=40$, the hash value is computed by Exclusive ORing the following three quantities: $(VA_{24:37} \parallel ^{25}0)$, $(0IIVA_{0:37})$, and $(^{b-1}0IIVA_{38:77-b})$

The 60-bit real address of a PTEG is formed by concatenating the following values:

- Bits 4:17 of SDR1 (the high-order 14 bits of HTABORG).
- Bits 0:27 of the 39-bit hash value ANDed with the mask generated from bits 59:63 of SDR1 (HTABSIZE) and then ORed with bits 18:45 of SDR1 (the low-order 28 bits of HTABORG).
- Bits 28:38 of the 39-bit hash value.
- Seven 0-bits.

This operation identifies a particular PTEG, called the “primary PTEG”, whose eight PTEs will be tested.

2. Secondary Hash:

If the secondary Page Table search is enabled ($LPCR_{TC}=0$), perform the secondary hash function as follows; otherwise do not perform step 2 and proceed to step 3 below.

If $s=28$, the hash value is computed by taking the ones complement of the Exclusive OR of $VA_{11:49}$ with $(^{11+b}0IIVA_{50:77-b})$

If $s=40$, the hash value is computed by taking the ones complement of the Exclusive OR of the following three quantities: $(VA_{24:37} \parallel ^{25}0)$, $(0IIVA_{0:37})$, and $(^{b-1}0IIVA_{38:77-b})$

The 60-bit real address of a PTEG is formed by concatenating the following values:

- Bits 4:17 of SDR1 (the high-order 14 bits of HTABORG).
- Bits 0:27 of the 39-bit hash value ANDed with the mask generated from bits 59:63 of SDR1 (HTABSIZE) and then ORed with bits 18:45 of SDR1 (the low-order 28 bits of HTABORG).
- Bits 28:38 of the 39-bit hash value.
- Seven 0-bits.

This operation identifies the “secondary PTEG”.

3. As many as 8 PTEs in the primary PTEG and, if the secondary Page Table search is enabled, 8 PTEs in the secondary PTEG are tested to determine if any translate the given virtual address. Let $q = \text{minimum}(54, 77-b)$. For a match to exist, the

following conditions must be satisfied, where SLBE is the SLBE used to form the virtual address.

- $PTE_H=0$ for the primary PTEG, 1 for the secondary PTEG
- $PTE_V=1$
- $PTE_B=SLBE_B$
- $PTE_{AVA[0:q]}=VA_{0:q}$
- if $PTE_L=0$ then $SLBE_{LILP}=0b000$
else PTE_{LP} specifies a base page size specified by $SLBE_{LILP}$

If no match is found, the search fails. If one match is found, the search succeeds. If more than one match is found, one of the matching entries is used as if it were the only matching entry, or a Machine Check occurs.

If the Page Table search succeeds, the real address (RA) is formed by concatenating bits 0:59-p of $ARNILP$ from the matching PTE with bits 64-p:63 of the effective address (the byte offset), where the p value is the \log_2 (actual page size specified by PTE_{LP}).

$$RA=(ARNILP)_{0:59-p} \parallel EA_{64-p:63}$$

Programming Note

If $PTE_L = 0$, the actual page size (and base page size) are 4 KB. Otherwise the actual page size and base page size are specified by PTE_{LP} .

Since hardware searches the Page Table using a value of b equal to \log_2 (base page size specified in the SLBE that was used to translate the address) regardless of the actual page size, the hardware page table search will identify different PTEs for VAs in different $2^{b\text{-byte}}$ blocks of the virtual page if the actual page size is larger than the base page size. Therefore, there may need to be a valid PTE corresponding to each 2^b block of the virtual page that is referenced. For an actual page size that is larger than 2^{23} (8 MB), the PTE_{AVA} will differ among some or all of these PTEs. Depending on the Page Table size, some or all of these PTEs may be in the same PTEG. Any such PTEs that are in the same PTEG will differ in the value of PTE_H or PTE_{AVA} or both.

All PTEs for the same virtual page should have the same values in the Page Protection, KEY, ARPN, WIMG, and N fields. A set of values from any one of the PTEs that maps the virtual page may be used for an access in the virtual page since lookaside buffer information may be used to translate the virtual address.

To avoid creating multiple matching PTEs, software should not create PTEs for each of two different virtual pages that overlap in the virtual address space. If the virtual page sizes differ, two virtual pages overlap if the values of virtual address bits 0:77-p for both virtual pages are the same, where 2^p is the actual virtual page size of the larger page.

The N (No-execute) value used for the storage access is the result of ORing the N bit from the matching PTE with the N bit from the SLB entry that was used to translate the effective address.

Programming Note

The value of b used when searching the Page Table to identify the PTEGs is \log_2 (base page size). Since a segment may contain pages of different sizes, the hardware searches for PTEs specifying pages of any supported size greater than or equal to the base page size, and the real address is formed using the value of p specified by the matching PTE.

A virtual page of 2^p bytes in a segment with a base page size of 2^b bytes may be mapped by as many as $2^{(b-p)}$ PTEs.

If the Page Table search fails, a *page fault* occurs. This is a [Hypervisor] Instruction Storage exception or a [Hypervisor] Data Storage exception, depending on whether the effective address is for an instruction fetch or for a data access. The N value used for the storage access is the N bit from the SLB entry that was used to translate the effective address.

Programming Note

To obtain the best performance, Page Table Entries should be allocated beginning with the first empty entry in the primary PTEG, or with the first empty entry in the secondary PTEG if the primary PTEG is full and the secondary Page Table search is enabled ($LPCR_{TC}=0$).

Translation Lookaside Buffer

Conceptually, the Page Table is searched by the address relocation hardware to translate every reference. For performance reasons, the hardware usually keeps a Translation Lookaside Buffer (TLB) that holds PTEs that have recently been used. Even though multiple PTEs may be needed for a virtual page whose size is larger than the base page size, one TLB entry derived from a single PTE may be used to translate all of the virtual addresses in the entire virtual page. The TLB is searched prior to searching the Page Table. As a consequence, when software makes changes to the Page Table it must perform the appropriate TLB invalidate operations to maintain the consistency of the TLB with the Page Table (see Section 5.10).

In the TLB search, the match criteria include virtual address bits 0:(77-q) where q is an implementation-dependent integer such that $b \leq q \leq p$. As a result of a Page Table search, multiple matching TLB entries are not created for the same virtual page, except that multiple matching TLB entries may be created if the Page Table contains PTEs that map different-sized virtual pages that overlap in the virtual address space. (If the

virtual page sizes differ, two virtual pages overlap if the values of virtual address bits 0:77-p for both virtual pages are the same, where 2^p is the actual virtual page size of the larger page.) If a TLB search finds multiple matching TLB entries created from such PTEs, one of the matching TLB entries is used as if it were the only matching entry, or a Machine Check occurs.

As a result of a Page Table search in a Page Table that does not contain different-sized virtual pages that overlap, it is implementation-dependent whether multiple non-matching TLB entries are created for the same virtual page. However, in this case if multiple TLB entries are created for a given virtual page, at most one matching TLB entry is created for any given virtual address in that virtual page, and q for that TLB entry is less than p .

An implementation may associate each of its TLB entries with the partition for which the TLB entry was created, so that the entries can be retained while other partitions are executing. In this case, when a valid TLB entry is created, the LPID value from LPIDR is written into the TLB entry.

Programming Notes

1. Page Table Entries may or may not be cached in a TLB.
2. It is possible that the hardware implements more than one TLB, such as one for data and one for instructions. In this case the size and shape of the TLBs may differ, as may the values contained therein.
3. Use the *tlbie* or *tlbia* instruction to ensure that the TLB no longer contains a mapping for a particular virtual page.

5.7.7.4 Relaxed Page Table Alignment [Category: Server.Relaxed Page Table Alignment]

The Page Table can be aligned on any 2^{18} byte (256 KB) boundary regardless of the HTAB size.

Section 5.7.7.2 describes the Storage Description Register, which includes the HTABORG field. That description generally applies except for the following difference. As the Page Table size is increased beyond 256 KB, the value in HTABORG need not have more of its low-order bits equal to 0. Instead, (HTABORG || ¹⁸0) is the real address of the start of the Page Table regardless of the Page Table size.

A Page Table search is performed as described in Section 5.7.7.3 except the 60-bit real address of a PTEG for both the primary and, if the secondary Page Table search is enabled, the secondary hash is formed by concatenating the following values:

- Bits 0:27 of the 39-bit appropriate primary or secondary hash value ANDed with the mask

generated from bits 59:63 of SDR1 (HTAB-SIZE) and then added to the value of bits 4:45 of SDR1 (HTABORG). This part of the real address differs from Section 5.7.7.2.

- Bits 28:38 of the 39-bit hash value.
- Seven 0-bits.

An outline of the PTEG real address computation is shown in Figure 19.

5.7.8 Reference and Change Recording

If address translation is enabled, Reference (R) and Change (C) bits are updated in any one of what could be multiple Page Table Entries that map the virtual page that is being accessed. If the storage operand of a *Load* or *Store* instruction crosses a virtual page boundary, the accesses to the components of the operand in each page are treated as separate and independent accesses to each of the pages for the purpose of setting the Reference and Change bits.

Reference and Change bits are set by the hardware as described below. Setting the bits need not be atomic with respect to performing the access that caused the bits to be updated. An attempt to access storage may cause one or more of the bits to be set (as described below) even if the access is not performed. The bits are updated in the Page Table Entry if the new value would otherwise be different from the old value for the virtual page, as determined by examining either the Page Table Entry or any lookaside information for the virtual page (e.g., TLB) maintained by the hardware.

Reference Bit

The Reference bit is set to 1 if the corresponding access (load, store, or instruction fetch) is required by the sequential execution model and is performed. Otherwise the Reference bit may be set to 1 if the corresponding access is attempted, either in-order or out-of-order, even if the attempt causes an exception, except that the Reference bit is not set to 1 for the access caused by an indexed *Move Assist* instruction for which the XER specifies a length of zero.

Change Bit

The Change bit is set to 1 if a *Store* instruction is executed and the store is performed. Otherwise in general the Change bit may be set to 1 if a *Store* instruction is executed and the store is permitted by the storage protection mechanism and, if the *Store* instruction is executed out-of-order, the instruction would be required by the sequential

execution model in the absence of the following kinds of interrupts:

- system-caused interrupts (see Section 6.4 on page 824)
- Floating-Point Enabled Exception type Program interrupts when the thread is in an Imprecise mode.

The only exception to the preceding statement is that the Change bit is not set to 1 if the instruction is a *Store String Indexed* instruction for which the XER specifies a length of zero.

Programming Note

A virtual page in a segment with a smaller base page size may be mapped by multiple PTEs. For each access of a virtual page, hardware may search the Page Table to update the R and C bits. If lookaside buffer information for the virtual page already indicates that all such bits to be set have already been set in a PTE that maps the virtual page, hardware need not make an update. Consider the following sequence of events:

1. A virtual page is mapped by 2 PTEs A and B and the R and C bits in both PTEs are 0.
2. A Load instruction accesses the virtual page and the R bit is updated in PTE A.
3. A Load instruction accesses the virtual page and the R bit is updated in PTE B.
4. A Store instruction accesses the virtual page and the C bit is updated in PTE B.
5. The virtual page is paged out. Software must examine both PTE A and B to get the state of the R and C bits for the virtual page.

Furthermore, if in event 2, PTE A was not found, a Data Storage interrupt or Hypervisor Data Storage interrupt may occur. Subsequently, if in event 3 or 4, PTE B was not found, a Data Storage interrupt or Hypervisor Data Storage interrupt may occur.

Programming Note

The following cases apply to virtual pages in a segment with a smaller page size, in which case there may be multiple PTEs for the virtual page.

- When a virtual page is accessed, hardware maintains the R and C bits in one or more of the PTEs corresponding to the referenced virtual page, and not necessarily the PTE that would be used if the Page Table were searched for the storage access (see Section 5.7.7.1). Therefore the R and C bits for a given virtual page in a segment with a smaller base page size may each be updated in a different PTE (subject to the requirements in Figure 28).
- If a virtual page access results in the R or C bits needing to be set to 1, the Page Table may be searched for any PTE corresponding to the virtual page accessed, and if the PTE is not found, a Data Storage Interrupt or Hypervisor Data Storage Interrupt may occur.

When the hardware updates the Reference and Change bits in the Page Table Entry, the accesses are performed as described in Section 5.7.3.5, “Storage Control Attributes for Implicit Storage Accesses” on page 777. The accesses may be performed using operations equivalent to a store to a byte, halfword, word, or doubleword, and are not necessarily performed as an atomic read/modify/write of the affected bytes.

These Reference and Change bit updates are not necessarily immediately visible to software. Executing a **sync** instruction ensures that all Reference and Change bit updates associated with address translations that were performed, by the thread executing the **sync** instruction, before the **sync** instruction is executed will be performed with respect to that thread before the **sync** instruction’s memory barrier is created. There are additional requirements for synchronizing Reference and Change bit updates in multi-threaded systems; see Section 5.10, “Page Table Update Synchronization Requirements” on page 818.

Programming Note

Because the **sync** instruction is execution synchronizing, the set of Reference and Change bit updates that are performed with respect to the thread executing the **sync** instruction before the memory barrier is created includes all Reference and Change bit updates associated with instructions preceding the **sync** instruction.

If software refers to a Page Table Entry when $MSR_{DR}=1$, the Reference and Change bits in the associated Page Table Entry are set as for ordinary loads and stores. See Section 5.10 for the rules software must follow when updating Reference and Change bits.

Figure 23 on page 789 summarizes the rules for setting the Reference and Change bits. The table applies to each atomic storage reference. It should be read from the top down; the first line matching a given situation applies. For example, if **stwcx** fails due to both a storage protection violation and the lack of a reservation, the Change bit is not altered.

In the figure, the “Load-type” instructions are the *Load* instructions described in Books I, II, and III-S, **eciwx**, and the *Cache Management* instructions that are treated as *Loads*. The “Store-type” instructions are the *Store* instructions described in Books I, II, and III-S, **ecowx**, and the *Cache Management* instructions that are treated as *Stores*. The “ordinary” *Load* and *Store* instructions are those described in Books I, II, and III-S. “set” means “set to 1”.

Status of Access	R	C
Indexed <i>Move Assist</i> insn w 0 len in XER	No	No
Storage protection violation	Acc ¹	No
Out-of-order I-fetch or <i>Load</i> -type insn or dcbtst	Acc	No
Out-of-order <i>Store</i> -type insn (except dcbtst)		
Would be required by the sequential execution model in the absence of system-caused or imprecise interrupts ³	Acc	Acc ^{1 2}
All other cases	Acc	No
In-order <i>Load</i> -type or <i>Store</i> -type insn, access not performed ⁴		
<i>Load</i> -type insn	Acc	No
<i>Store</i> -type insn	Acc	Acc ²
Other in-order access		
I-fetch	Yes	No
Ordinary <i>Load</i> , eciwx	Yes	No
Other ordinary <i>Store</i> , ecowx , dcbz	Yes	Yes
icbi , dcbt , dcbtst , dcbst , dcbf[l]	Acc	No
<p>“Acc” means that it is acceptable to set the bit.</p> <p>¹ It is preferable not to set the bit.</p> <p>² If C is set, R is also set unless it is already set.</p> <p>³ For Floating-Point Enabled Exception type Program interrupts, “imprecise” refers to the exception mode controlled by MSR_{FE0 FE1}.</p> <p>⁴ This case does not apply to the <i>Touch</i> instructions, because they do not cause a storage access.</p>		

Figure 23. Setting the Reference and Change bits

5.7.9 Storage Protection

The storage protection mechanism provides a means for selectively granting instruction fetch access, granting read access, granting write access, and prohibiting access to areas of storage based on a number of control criteria.

The operation of the storage protection mechanism depends on the contents of one or more of the following.

- MSR bits HV, IR, DR, PR
- the key bits in the associated SLB entry
- the page protection bits and key bits in the associated PTE
- the AMR, AMOR, and UAMOR
- LPCR bits LPES₁ and VPM₀

The storage protection mechanism consists of the Virtual Page Class Key Protection mechanism, described in Section 5.7.9.1, and the Basic Storage Protection mechanism, described in Section 5.7.9.2 and Section 5.7.9.3.

When address translation is enabled for an access, the access is permitted if and only if the access is permitted by both the Virtual Page Class Key Protection mechanism and the Basic Storage Protection mechanism. When address translation is disabled for an access, the access is permitted if and only if the access is permitted by the Basic Storage Protection mechanism. If an instruction fetch is not permitted, an Instruction Storage exception or a Hypervisor Instruction Storage exception is generated. If a data access is not permitted, a Data Storage exception or a Hypervisor Data Storage exception is generated.

A *protection domain* is a maximal range of effective addresses for which variables related to storage protection can be independently specified (including by default, as in real and hypervisor real addressing modes), or a maximal range of addresses, effective or virtual, for which variables related to storage protection cannot be specified. Examples include: a segment, a virtual page (including for a virtualized Real Mode Area), the Real Mode Area (regardless of whether the RMA is virtualized), the effective address range 0:2⁶⁰-1 in hypervisor real addressing mode, and a maximal range of effective or virtual addresses that cannot be mapped to real addresses. A *protection boundary* is a boundary between protection domains.

5.7.9.1 Virtual Page Class Key Protection

The Virtual Page Class Key Protection mechanism provides the means to assign virtual pages to one of 32 classes, and to modify access permissions for each class quickly by modifying the Authority Mask Register

(AMR), shown in Figure 24. The access permissions associated with the Virtual Page Class Key Protection mechanism apply only to data accesses, and only when address translation is enabled. The Virtual Page Class Key Protection mechanism has no effect on instruction fetches.

Programming Note

If address translation is disabled for a given access, the access is not affected by the Virtual Page Class Key Protection mechanism even if the access is made in virtual real addressing mode.

Key0	Key1	Key2	...	Key29	Key30	Key31
0	2	4	6	58	60	62

Bits	Name	Description
0:1	Key0	Access mask for class number 0
2:3	Key1	Access mask for class number 1
...
2n:2n+1	Keyn	Access mask for class number n
...
62:63	Key31	Access mask for class number 31

Figure 24. Authority Mask Register (AMR)

The access mask for each class defines the access permissions that apply to loads and stores for which the virtual address is translated using a Page Table Entry that contains a KEY field value equal to the class number. The access permissions associated with each class are defined as follows, where AMR_{2n} and AMR_{2n+1} refer to the first and second bits of the access mask corresponding to class number n.

- A store is permitted if AMR_{2n}=0b0; otherwise the store is not permitted.
- A load is permitted if AMR_{2n+1}=0b0; otherwise the load is not permitted.

The AMR can be accessed using either SPR 13 or SPR 29. Access to the AMR using SPR 29 is privileged.

Programming Note

Because the AMR is part of the program context (if address translation is enabled), and because it is desirable for most application programmers not to have to understand the software synchronization requirements for context alterations (or the nuances of address translation and storage protection), operating systems should provide a system library program that application programs can use to modify the AMR.

The Authority Mask Override Register (AMOR) and the User Authority Mask Override Register (UAMOR), shown in Figure 25 and Figure 26 respectively, can be

used to restrict modifications (*mtspr*) of the AMR. Also, the AMOR can be used to restrict modifications of the UAMOR. Access to both registers is privileged. The AMOR is a hypervisor resource.

Figure 25. Authority Mask Override Register (AMOR)

Figure 26. User Authority Mask Override Register (UAMOR)

The bits of the AMOR and UAMOR are in 1-1 correspondence with the bits of the AMR (i.e., [U]AMOR_i corresponds to AMR_i). The AMOR affects modifications of the AMR and UAMOR in privileged but non-hypervisor state; the UAMOR affects modifications of the AMR in problem state.

- When *mtspr* specifying the AMR (using either SPR 13 or SPR 29) is executed in privileged but non-hypervisor state, the AMOR is used as a mask that controls which bits of the resulting AMR contents come from register RS and which AMR bits are not modified.
- Similarly, when *mtspr* specifying the AMR (using SPR 13) is executed in problem state, the UAMOR is used as a mask that controls which bits of the resulting AMR contents come from register RS and which AMR bits are not modified.
- When *mtspr* specifying the UAMOR is executed in privileged but non-hypervisor state, the AMOR is ANDed with the contents of register RS and the result is placed into the UAMOR; the AMOR thereby controls which bits of the resulting UAMOR contents come from register RS and which UAMOR bits are set to zero.

A complete description of these effects can be found in the description of the *mtspr* instruction on page 763.

Software must ensure that both bits of each even/odd bit pair of the AMOR contain the same value. — i.e., the contents of register RS for *mtspr* specifying the AMOR must be such that $(RS)_{2n} = (RS)_{2n+1}$ for every n in the range 0:31 — and likewise for the UAMOR. If this requirement is violated for the UAMOR the results of accessing the UAMOR (including implicitly by the hardware as described in the second item of the preceding list) are boundedly undefined; if the requirement is violated for the AMOR the results of accessing the AMOR (including implicitly by the hardware as described in the first and third items of the list) are undefined.

Programming Note

The preceding requirement permits designs to implement the AMOR and/or UAMOR as 32-bit registers — specifically, to implement only the even-numbered bits (or only the odd-numbered bits) of the register — in a manner such that the reduction, from the architecturally-required 64 bits to 32 bits, is not visible to (correct) software. This implementation technique saves space in the hardware. (A design that uses this technique does the appropriate “fan in/out” when the register is accessed, to provide the appearance, to (correct) software, of supporting all 64 bits of the register.)

Permitting designs to implement the [U]AMOR as 32-bit registers by virtue of the software requirement specified above, rather than by defining the [U]AMOR as 32-bit registers, permits the architecture to be extended in the future to support controlling modification of the “read access” AMR bits (the odd-numbered bits) independently from the “write access” AMR bits (the even-numbered bits), if that proves desirable. If this independent control does prove desirable, the only architecture change would be to eliminate the software requirement.

Programming Note

When modifying the AMOR and/or UAMOR, the hypervisor should ensure that the two registers are consistent with one another before giving control to a non-hypervisor program. In particular, the hypervisor should ensure that if $AMOR_i=0$ then $UAMOR_i=0$, for all i in the range 0:63. (Having $AMOR_i=0$ and $UAMOR_i=1$ would permit problem state programs, but not the operating system, to modify AMR bit i .)

Programming Note

The Virtual Page Class Key Protection mechanism replaces the Data Address Compare mechanism that was defined in versions of the architecture that precede Version 2.04 (e.g., the two facilities use some of the same resources, as described below). However, the Virtual Page Class Key Protection mechanism can be used to emulate the Data Address Compare mechanism. Moreover, programs that use the Data Address Compare mechanism can be modified in a manner such that they will work correctly both on implementations that comply with versions of the architecture that precede Version 2.04 (and hence implement the Data Address Compare mechanism) and on implementations that comply with Version 2.04 of the architecture or with any subsequent version (and hence instead implement the Virtual Page Class Key Protection mechanism). The technique takes advantage of the facts that the SPR number for privileged access to the AMR (29) is the same as the SPR number for the Data Address Compare mechanism's ACCR (Address Compare Control Register), that KEY_4 occupies the same bit in the PTE as the Data Address Compare mechanism's AC (Address Compare) bit, and that the definition of $ACCR_{62:63}$ is very similar to the definition of each even-odd pair of AMR bits. The technique is as follows, where PTE1 refers to doubleword 1 of the PTE.

- Set bits 2:3 and 62:63 of SPR 29 (which is either the ACCR or the AMR) to x , where x is the desired 2-bit value for controlling Data Address Compare matches, and set bits 0:1 to 0s.
- Set $PTE1_{54}$ (which is either the AC bit or KEY_4) to the same value that the AC bit would be set to, and set $PTE1_{2:3}$ (which are either RPN bits, that correspond to a real address size larger than the size supported by any implementation that supports the Data Address Compare mechanism, or $KEY_{0:1}$) and $PTE1_{52:53}$ (which are either reserved bits or $KEY_{2:3}$) to 0s.
- Use PTE_{KEY} values 0 and 1 only for purposes of emulating the Data Address Compare mechanism, except that PTE_{KEY} value 0 may also be used for any virtual pages for which it is desired that the Virtual Page Class Key Protection mechanism permit all accesses. Do not use $PTE_{KEY}=31$.
- When a Data Storage interrupt occurs, if $DSISR_{42}=1$ then ignore the interrupt for *Cache Management* instructions other than **dcbz**. (These instructions can cause a virtual page class key protection violation but cannot cause a Data Address Compare match.) Otherwise treat the interrupt as if a Data Address Compare match had occurred. (Note: Cases for which it is undefined whether a Data Address Compare match occurs do not necessarily cause a virtual page class key protection violation.)

(Because privileged software can access the AMR using either SPR 13 or SPR 29, it might seem that, when SPR 13 was added to the architecture (in Version 2.06), SPR 29 should have been removed. SPR 29 is retained for two reasons: first, to avoid requiring privileged software to change to use the newer SPR number; and second, to retain the ability to emulate the Data Address Compare mechanism as described above.)

Programming Note

An example of the use of the AMOR (and UAMOR) is to support lightweight partitions, here called “adjunct” partitions, that provide services (e.g., device drivers) to “client” partitions. The adjunct partition would be managed by the hypervisor. It would run in problem state with $MSR_{HV_PR}=0b11$, thereby restricting the resources it can modify ($MSR_{PR}=1$) and causing its interrupts to go to the hypervisor ($MSR_{HV}=1$), and it would share a Page Table with the client partition it serves. Typically, each of the two partitions would have data storage that the other partition must not be able to access. The hypervisor can use the AMOR, UAMOR, AMR, and PTE KEY field to provide the required protection. (The adjunct partition’s lightness of weight derives from not requiring an operating system, and especially from not requiring a full partition context switch (SLB flush, TLB flush, SDR1 change, etc.) when the client partition invokes the services of the adjunct partition.)

For example, suppose each of the two partitions must not be able to access any of the other partition’s data storage. The hypervisor could use KEY value j for all data virtual pages that only the adjunct partition must be able to access. Before dispatching the client partition for the first time, the hypervisor would initialize the three registers as follows.

AMR: all 0s except bits $2j$ and $2j+1$, which would contain 1s

UAMOR: all 0s

AMOR: all 1s except bits $2j$ and $2j+1$, which would contain 0s

Before dispatching the adjunct partition, the hypervisor would set UAMOR to all 0s, and would set the AMR to all 1s except bits $2j$ and $2j+1$, which would be set to 0s. (Because the adjunct partition would run in problem state, there is no need for the hypervisor to modify the AMOR, and the adjunct partition cannot modify the UAMOR.) In addition, the hypervisor would prevent the client partition from modifying or deleting PTEs that contain translations used by the adjunct partition.

(It may be desirable to avoid using KEY values 0, 1, and 31 for storage that only the adjunct partition can access, because these KEY values may be needed by the client partition to emulate the Data Address Compare mechanism, as described above. Also, old software, that was written for an implementation that complies with a version of the architecture that precedes Version 2.04 (the version in which virtual page class keys were added), effectively uses KEY 0 for all virtual pages.)

Programming Note

Initialization of the UAMOR to all 0s, by the hypervisor before dispatching a partition for the first time, as described in the preceding Programming Note, permits operating systems (in partitions that run in a compatibility mode corresponding to Version 2.06 of the architecture or a subsequent version) to migrate gradually to supporting problem state access to the AMR — specifically, to avoid having to be changed immediately to modify the UAMOR and to save the AMR contents when an interrupt occurs from problem state. Relatedly, having the UAMOR contain all 0s while an application program is running protects old application programs that are “AMR-unaware”. In the absence of programming errors, such application programs would not attempt to read or modify the AMR. However, having the UAMOR contain all 0s protects such programs against modifying the AMR inadvertently.

Permitting an “AMR-unaware” application program to modify the AMR (inadvertently) is potentially harmful for the obvious reasons. (The program might set to 1 an AMR bit corresponding to accesses that are necessary in order for the program to work correctly.) Moreover, even for an operating system that includes support for problem state modification of the AMR, having the UAMOR contain all 0s allows the operating system to avoid saving and restoring the AMR for “AMR-unaware” application programs. Such an operating system would provide a system service program that allows an application program to declare itself to be “AMR-aware” — i.e., potentially to need to modify the AMR. When an application program invokes this service, the operating system would set the UAMOR to the non-zero value appropriate to the access authorities (load and/or store, for one or more key values) that the application program is allowed to modify, and thereafter would save and restore the AMR (and preserve the UAMOR) for this application program. (Having the UAMOR contain all 0s does not prevent an “AMR-unaware” program from reading the AMR, but inadvertent reading of the AMR is likely to be much less harmful than inadvertently modifying it.)

(For partitions that run in a compatibility mode corresponding to a version of the architecture that precedes Version 2.06, the PCR provides sufficient protection to application programs.)

5.7.9.2 Basic Storage Protection, Address Translation Enabled

When address translation is enabled, the Basic Storage Protection mechanism is controlled by the following.

- MSR_{PR} , which distinguishes between supervisor (privileged) state and problem state

- K_S and K_P , the supervisor (privileged) state and problem state storage key bits in the SLB entry used to translate the effective address
- PP, page protection bits 0:2 in the Page Table Entry used to translate the effective address
- For instruction fetches only:
 - the N (No-execute) value used for the access (see Sections 5.7.6.1 and 5.7.7.3)
 - PTE_G , the G (Guarded) bit in the Page Table Entry used to translate the effective address

Using the above values, the following rules are applied.

1. For an instruction fetch, the access is not permitted if the N value is 1 or if $PTE_G=1$.
2. For any access except an instruction fetch that is not permitted by rule 1, a “Key” value is computed using the following formula:

$$Key \leftarrow (K_P \ \& \ MSR_{PR}) \ | \ (K_S \ \& \ \neg MSR_{PR})$$

Using the computed Key, Figure 27 is applied. An instruction fetch is permitted for any entry in the figure except “no access”. A load is permitted for any entry except “no access”. A store is permitted only for entries with “read/write”.

Key	PP	Access Authority
0	000	read/write
0	001	read/write
0	010	read/write
0	011	read only
0	110	read only
1	000	no access
1	001	read only
1	010	read/write
1	011	read only
1	110	no access

All PP encodings not shown above are reserved. The results of using reserved PP encodings are boundedly undefined.

Figure 27. PP bit protection states, address translation enabled

5.7.9.3 Basic Storage Protection, Address Translation Disabled

When address translation is disabled, the Basic Storage Protection mechanism is controlled by the following (see Chapter 2 and Section 5.7.3, “Real And Virtual Real Addressing Modes”).

- MSR_{HV} , which (when $MSR_{PR}=0$) distinguishes between hypervisor state and privileged but non-hypervisor state
- $LPES_1$, which controls whether storage accesses are permitted in real addressing mode

- VPM_0 , which distinguishes between real addressing mode and virtual real addressing mode
- RMLS, which specifies the real mode limit value

Using the above values, the following rules are applied.

1. If $MSR_{HV}=0$ and $LPES_1=1$ and $VPM_0=1$, access authority is determined as described in Section 5.7.3.4.
2. If $MSR_{HV}=1$ or $LPES_1=0$ or $VPM_0=0$, Figure 28 is applied. The access is permitted for any entry in the figure except “no access”.

$LPES_1$	HV	Access Authority
0	0	no access
0	1	read/write
1	0	read/write or no access ¹
1	1	read/write

¹ If the effective address for the access is less than the value specified by the RMLS, the access authority is read/write; otherwise the access is not permitted.

Figure 28. Protection states, address translation disabled

Programming Note

The comparison described in note 1 in Figure 28 ignores bits 0:3 of the effective address and may ignore bits 4:63-m; see Section 5.7.3.

5.8 Storage Control Attributes

This section describes aspects of the storage control attributes that are relevant only to privileged software programmers. The rest of the description of storage control attributes may be found in Section 1.6 of Book II and subsections.

5.8.1 Guarded Storage

Storage is said to be “well-behaved” if the corresponding real storage exists and is not defective, and if the effects of a single access to it are indistinguishable from the effects of multiple identical accesses to it. Data and instructions can be fetched out-of-order from well-behaved storage without causing undesired side effects.

Storage is said to be Guarded if any of the following conditions is satisfied.

- MSR bit IR or DR is 1 for instruction fetches or data accesses respectively, and the G bit is 1 in the relevant Page Table Entry.
- MSR bit IR or DR is 0 for instruction fetches or data accesses respectively, $MSR_{HV}=1$, and the storage is outside the range(s) specified by the Hypervisor Real Mode Storage Control facility (see Section 5.7.3.3.1).

In general, storage that is not well-behaved should be Guarded. Because such storage may represent a control register on an I/O device or may include locations that do not exist, an out-of-order access to such storage may cause an I/O device to perform unintended operations or may result in a Machine Check.

The following rules apply to in-order execution of *Load* and *Store* instructions for which the first byte of the storage operand is in storage that is both Caching Inhibited and Guarded.

- *Load* or *Store* instruction that causes an atomic access

If any portion of the storage operand has been accessed and an External, Decrementer, Hypervisor Decrementer, or Imprecise mode Floating-Point Enabled exception is pending, the instruction completes before the interrupt occurs.

- *Load* or *Store* instruction that causes an Alignment exception, or that causes a [Hypervisor] Data Storage exception for reasons other than Data Address Breakpoint match.

The portion of the storage operand that is in Caching Inhibited and Guarded storage is not accessed.

(The corresponding rules for instructions that cause a Data Address Breakpoint match are given in Section 8.1.2.)

5.8.1.1 Out-of-Order Accesses to Guarded Storage

In general, Guarded storage is not accessed out-of-order. The only exceptions to this rule are the following.

Load Instruction

If a copy of any byte of the storage operand is in a cache then that byte may be accessed in the cache or in main storage.

Instruction Fetch

If $MSR_{HV} IR=0b10$ then an instruction may be fetched if any of the following conditions are met.

1. The instruction is in a cache. In this case it may be fetched from the cache or from main storage.
2. The instruction is in a real page from which an instruction has previously been fetched, except that if that previous fetch was based on condition 1 then the previously fetched instruction must have been in the instruction cache.
3. The instruction is in the same real page as an instruction that is required by the sequential execution model, or is in the real page immediately following such a page.

Programming Note

Software should ensure that only well-behaved storage is copied into a cache, either by accessing as Caching Inhibited (and Guarded) all storage that may not be well-behaved, or by accessing such storage as not Caching Inhibited (but Guarded) and referring only to cache blocks that are well-behaved.

If a real page contains instructions that will be executed when $MSR_{IR}=0$ and $MSR_{HV}=1$, software should ensure that this real page and the next real page contain only well-behaved storage (or that the Hypervisor Real Mode Storage Control facility specifies that this real page is not Guarded).

5.8.2 Storage Control Bits

When address translation is enabled, each storage access is performed under the control of the Page Table Entry used to translate the effective address. Each Page Table Entry contains storage control bits that specify the presence or absence of the corresponding storage control for all accesses translated by the entry as shown in Figure 29.

Bit	Storage Control Attribute
W ^{1,3}	0 - not Write Through Required 1 - Write Through Required
I ³	0 - not Caching Inhibited 1 - Caching Inhibited
M ²	0 - not Memory Coherence Required 1 - Memory Coherence Required
G	0 - not Guarded 1 - Guarded
<p>¹ Support for the 1 value of the W bit is optional. Implementations that do not support the 1 value treat the bit as reserved and assume its value to be 0.</p> <p>² [Category: Memory Coherence] Support for the 0 value of the M bit is optional, implementations that do not support the 0 value assume the value of the bit to be 1, and may either preserve the value of the bit or write it as 1.</p> <p>³ [Category: SAO] The combination WIMG = 0b1110 has behavior unrelated to the meanings of the individual bits. See Section 5.8.2.1, “Storage Control Bit Restrictions” for additional information.</p>	

Figure 29. Storage control bits

When address translation is enabled, instructions are not fetched from storage for which the G bit in the Page Table Entry is set to 1; see Section 5.7.9.

When address translation is disabled, the storage control attributes are implicit; see Section 5.7.3.3.

In Sections 5.8.2.1 and 5.8.2.2, “access” includes accesses that are performed out-of-order, and references to W, I, M, and G bits include the values of those bits that are implied when address translation is disabled.

Programming Note

In a system consisting of only a single-threaded processor which has caches, correct coherent execution does not require storage to be accessed as Memory Coherence Required, and accessing storage as not Memory Coherence Required may give better performance.

5.8.2.1 Storage Control Bit Restrictions

All combinations of W, I, M, and G values are permitted except those for which both W and I are 1 and MIMG ≠ 0b10.

The combination WIMG = 0b1110 is used to identify the Strong Access Ordering (SAO) storage attribute (see Section 1.7.1, “Storage Access Ordering”, in Book II). Because this attribute is not intended for general purpose programming, it is provided only for a single

combination of the attributes normally identified using the WIMG bits. That combination would normally be indicated by WIMG = 0b0010.

References to Caching Inhibited storage (or storage with I=1) elsewhere in the Power ISA have no application to SAO storage or its WIMG encoding, despite the encoding using I=1. Conversely, references to storage that is not Caching Inhibited (or storage with I=0) apply to SAO storage or its WIMG encoding. References to Write Through Required storage (or storage with W=1) elsewhere in the Power ISA have no application to SAO storage or its WIMG encoding, despite the fact that the encoding uses W=1. Conversely, references to storage that is not Write Through Required (or storage with W=0) apply to SAO storage or its WIMG encoding.

If a given real page is accessed concurrently as SAO storage and as non-SAO storage, the result may be characteristic of the weakly consistent model.

Programming Note

If an application program requests both the Write Through Required and the Caching Inhibited attributes for a given storage location, the operating system should set the I bit to 1 and the W bit to 0. For implementations that support the SAO category, the operating system should provide a means by which application programs can request SAO storage, in order to avoid confusion with the preceding guideline (since SAO is encoded using WI=0b11).

At any given time, the value of the W bit must be the same for all accesses to a given real page.

At any given time, the value of the I bit must be the same for all accesses to a given real page.

5.8.2.2 Altering the Storage Control Bits

When changing the value of the W bit for a given real page from 0 to 1, software must ensure that no thread modifies any location in the page until after all copies of locations in the page that are considered to be modified in the data caches have been copied to main storage using **dcbst** or **dcbf[]**.

When changing the value of the I bit for a given real page from 0 to 1, software must set the I bit to 1 and then flush all copies of locations in the page from the caches using **dcbf[]** and **icbi** before permitting any other accesses to the page.

Programming Note

The storage control bit alterations described above are examples of cases in which the directives for application of statements about the W and I bits to SAO given in the third paragraph of the preceding subsection must be applied. A transition from the typical WIMG=0b0010 for ordinary storage to WIMG=0b1110 for SAO storage does not require the flush described above because both WIMG combinations indicate storage that is not Caching Inhibited.

Programming Note

It is recommended that ***dcbf*** be used, rather than ***dcbfl***, when changing the value of the I or W bit from 0 to 1. (***dcbfl*** would have to be executed on all threads for which the contents of the data cache may be inconsistent with the new value of the bit, whereas, if the M bit for the page is 1, ***dcbf*** need be executed on only one thread in the system.)

When changing the value of the M bit for a given real page, software must ensure that all data caches are consistent with main storage. The actions required to do this are system-dependent.

Programming Note

For example, when changing the M bit in some directory-based systems, software may be required to execute ***dcbf[I]*** on each thread to flush all storage locations accessed with the old M value before permitting the locations to be accessed with the new M value.

Additional requirements for changing the storage control bits in the Page Table are given in Section 5.10.

5.9 Storage Control Instructions

5.9.1 Cache Management Instructions

This section describes aspects of cache management that are relevant only to privileged software programmers.

For a **dcbz** instruction that causes the target block to be newly established in the data cache without being fetched from main storage, the hardware need not verify that the associated real address is valid. The existence of a data cache block that is associated with an invalid real address (see Section 5.6) can cause a

delayed Machine Check interrupt or a delayed Check-stop.

Each implementation provides an efficient means by which software can ensure that all blocks that are considered to be modified in the data cache have been copied to main storage before the thread enters any power conserving mode in which data cache contents are not maintained.

5.9.2 Synchronize Instruction

The *Synchronize* instruction is described in Section 4.4.3 of Book II, but only at the level required by an application programmer (**sync** with L=0 or L=1). This section describes properties of the instruction that are relevant only to operating system and hypervisor software programmers. This variant of the *Synchronize* instruction is designated the Page Table Entry **sync** and is specified by the extended mnemonic **ptesync** (equivalent to **sync** with L=2).

The **ptesync** instruction has all of the properties of **sync** with L=0 and also the following additional properties.

- The memory barrier created by the **ptesync** instruction provides an ordering function for the storage accesses associated with all instructions that are executed by the thread executing the **ptesync** instruction and, as elements of set A, for all Reference and Change bit updates associated with additional address translations that were performed, by the thread executing the **ptesync** instruction, before the **ptesync** instruction is executed. The applicable pairs are all pairs a_i, b_j in which b_j is a data access and a_i is not an instruction fetch.
- The **ptesync** instruction causes all Reference and Change bit updates associated with address translations that were performed, by the thread executing the **ptesync** instruction, before the **ptesync** instruction is executed, to be performed with respect to that thread before the **ptesync** instruction's memory barrier is created.
- The **ptesync** instruction provides an ordering function for all stores to the Page Table caused by *Store* instructions preceding the **ptesync** instruction with respect to searches of the Page Table that are performed, by the thread executing the **ptesync** instruction, after the **ptesync** instruction completes. Executing a **ptesync** instruction ensures that all such stores will be performed, with

respect to the thread executing the **ptesync** instruction, before any implicit accesses to the affected Page Table Entries, by such Page Table searches, are performed with respect to that thread.

- In conjunction with the **tlbie** and **tlbsync** instructions, the **ptesync** instruction provides an ordering function for TLB invalidations and related storage accesses on other threads as described in the **tlbsync** instruction description on page 817.

Programming Note

For instructions following a **ptesync** instruction, the memory barrier need not order implicit storage accesses for purposes of address translation and reference and change recording.

The functions performed by the **ptesync** instruction may take a significant amount of time to complete, so this form of the instruction should be used only if the functions listed above are needed. Otherwise **sync** with L=0 should be used (or **sync** with L=1, or **eieio**, if appropriate).

Section 5.10, "Page Table Update Synchronization Requirements" on page 818 gives examples of uses of **ptesync**.

5.9.3 Lookaside Buffer Management

All implementations have a Segment Lookaside Buffer (SLB). For performance reasons, most implementations also have implementation-specific lookaside information that is used in address translation. This lookaside information may be: a Translation Lookaside Buffer (TLB) which is a cache of recently used Page

Table Entries (PTEs); a cache of recently used translations of effective addresses to real addresses; etc.; or any combination of these. Lookaside information, including the SLB, is managed using the instructions described in the subsections of this section.

Lookaside information derived from PTEs is not necessarily kept consistent with the Page Table. When software alters the contents of a PTE, in general it must also invalidate all corresponding implementation-specific lookaside information; exceptions to this rule are described in Section 5.10.1.2.

The effects of the *slbie*, *slbia*, and *TLB Management* instructions on address translations, as specified in Sections 5.9.3.1 and 5.9.3.3 for the SLB and TLB respectively, apply to all implementation-specific lookaside information that is used in address translation. Unless otherwise stated or obvious from context, references to SLB entry invalidation and TLB entry invalidation elsewhere in the Books apply also to all implementation-specific lookaside information that is derived from SLB entries and PTEs respectively.

The *tlbia* instruction is optional. However, all implementations provide a means by which software can invalidate all implementation-specific lookaside information that is derived from PTEs.

Implementation-specific lookaside information that contains translations of effective addresses to real addresses may include “translations” that apply in real addressing mode. Because such “translations” are affected by the contents of the LPCR, RMOR, and HRMOR, when software alters the contents of these registers it must also invalidate the corresponding implementation-specific lookaside information. Software can invalidate all such lookaside information by using the *slbia* instruction with IH=0b000. However, performance is likely to be better if other, appropriate, IH values are used to limit the amount of lookaside information that is invalidated.

All implementations that have such lookaside information provide a means by which software can invalidate all such lookaside information.

For simplicity, elsewhere in the Books it is assumed that the TLB exists.

Programming Note

Because the instructions used to manage implementation-specific lookaside information that is derived from PTEs may be changed in a future version of the architecture, it is recommended that software “encapsulate” uses of the *TLB Management* instructions into subroutines.

Programming Note

The function of all the instructions described in Sections 5.9.3.1 - 5.9.3.3 is independent of whether address translation is enabled or disabled.

For a discussion of software synchronization requirements when invalidating SLB and TLB entries, see Chapter 10.

5.9.3.1 SLB Management Instructions

Programming Note

Accesses to a given SLB entry caused by the instructions described in this section obey the sequential execution model with respect to the contents of the entry and with respect to data dependencies on those contents. That is, if an instruction sequence contains two or more of these instructions, when the sequence has completed, the final contents of the SLB entry and of General Purpose Registers is as if the instructions had been executed in program order.

However, software synchronization is required in order to ensure that any alterations of the entry take effect correctly with respect to address translation; see Chapter 10.

SLB Invalidate Entry**X-form**

slbie RB

31	///	///	RB	434	/
0	6	11	16	21	31

```

ea0:35 ← (RB)0:35
if, for SLB entry that translates
  or most recently translated ea,
  entry_class = (RB)36 and
  entry_seg_size = size specified in (RB)37:38
then for SLB entry (if any) that translates ea
  SLBEV ← 0
  all other fields of SLBE ← undefined
else
  s ← log_base_2(entry_seg_size)
  esid ← (RB)0:63-s
  u ← undefined 1-bit value
  if u then
    if an SLB entry translates esid
      SLBEV ← 0
      all other fields of SLBE ← undefined

```

Let the Effective Address (EA) be any EA for which $EA_{0:35} = (RB)_{0:35}$. Let the class be $(RB)_{36}$. Let the segment size be equal to the segment size specified in $(RB)_{37:38}$; the allowed values of $(RB)_{37:38}$, and the correspondence between the values and the segment size, are the same as for the B field in the SLBE (see Figure 17 on page 779).

The class value and segment size must be the same as the class value and segment size in the SLB entry that translates the EA, or the values that were in the SLB entry that most recently translated the EA if the translation is no longer in the SLB; if these values are not the same, it is implementation-dependent whether the SLB entry (or implementation-dependent translation information) that translates the EA is invalidated, and the next paragraph need not apply.

If the SLB contains only a single entry that translates the EA, then that is the only SLB entry that is invalidated, except that it is implementation-dependent whether an implementation-specific lookaside entry for a real mode address “translation” is invalidated. If the SLB contains more than one such entry, then zero or more such entries are invalidated, and similarly for any implementation-specific lookaside information used in address translation; additionally, a machine check may occur.

SLB entries are invalidated by setting the V bit in the entry to 0, and the remaining fields of the entry are set to undefined values.

The hardware ignores the contents of RB listed below and software must set them to 0s.

- $(RB)_{37}$
- $(RB)_{39:63}$
- If $s = 40$, $(RB)_{24:35}$

If this instruction is executed in 32-bit mode, $(RB)_{0:31}$ must be zeros.

This instruction is privileged.

Special Registers Altered:

None

Programming Note

slbie does not affect SLBs on other threads.

Programming Note

The reason the class value specified by *slbie* must be the same as the Class value that is or was in the relevant SLB entry is that the hardware may use these values to optimize invalidation of implementation-specific lookaside information used in address translation. If the value specified by *slbie* differs from the value that is or was in the relevant SLB entry, these optimizations may produce incorrect results. (An example of implementation-specific address translation lookaside information is the set of recently used translations of effective addresses to real addresses that some implementations maintain in an Effective to Real Address Translation (ERAT) lookaside buffer.)

When switching tasks in certain cases, it may be advantageous to preserve some implementation-specific lookaside entries while invalidating others. The $IH=0b001$ invalidation hint of the *slbia* instruction can be used for this purpose if SLB class values are appropriately assigned, i.e. a class value of 0 gives the hint that the entry should be preserved and a class value of 1 indicates the entry must be invalidated. Also, it is advantageous to assign a class value of 1 to entries that need to be invalidated via an *slbie* instruction while preserving implementation-specific lookaside entries that are not derived from an SLB entry since such entries are assigned a class value of 0.

The *Move To Segment Register* instructions (see Section 5.9.3.2.1) create SLB entries in which the Class value is 0.

Programming Note

The B value in register RB may be needed for invalidating ERAT entries corresponding to the translation being invalidated.

SLB Invalidate All**X-form**

slbia IH

0	31	//	IH	///	///	498	/
	6	8	11	16	21	31	

for each SLB entry except SLB entry 0
 SLBE_v ← 0
 all other fields of SLBE ← undefined

For all SLB entries except SLB entry 0, the V bit in the entry is set to 0, making the entry invalid, and the remaining fields of the entry are set to undefined values. SLB entry 0 is not altered.

On implementations that have implementation-specific lookaside information for effective to real address translations, the IH field provides a hint that can be used to invalidate entries selectively in such lookaside information. The defined values for IH are as follows.

- 0b000 All such implementation-specific lookaside information is invalidated. (This value is not a hint.)
- 0b001 Preserve such implementation-specific lookaside information having a Class value of 0.
- 0b010 Preserve such implementation-specific lookaside information created when MSR_{IR/DR}=0.
- 0b110 Preserve such implementation-specific lookaside information created when MSR_{HV}=1, MSR_{PR}=0, and MSR_{IR/DR}=0.

All other IH values are reserved. If the IH field contains a reserved value, the hint provided by the IH field is undefined.

Implementation specific lookaside information for which preservation is not requested is invalidated. Implementation specific lookaside information for which preservation is requested may be invalidated.

When IH=0b000, execution of this instruction has the side effect of clearing the storage access history associated with the Hypervisor Real Mode Storage Control facility. See Section 5.7.3.3.1, “Hypervisor Real Mode Storage Control” for more details.

This instruction is privileged.

Special Registers Altered:

None

Programming Note

slbia does not affect SLBs on other threads.

Programming Note

If **slbia** is executed when instruction address translation is enabled, software can ensure that attempting to fetch the instruction following the **slbia** does not cause an Instruction Segment interrupt by placing the **slbia** and the subsequent instruction in the effective segment mapped by SLB entry 0. (The preceding assumes that no other interrupts occur between executing the **slbia** and executing the subsequent instruction.)

Programming Note

The defined values for IH are as follows.

- 0b000 All ERAT entries are invalidated. (This value is not a hint.) This value should be used by the hypervisor when relocating itself (i.e. when modifying the HRMOR) or when reconfiguring real storage.
- 0b001 Preserve ERAT entries with a Class value of 0. This value should be used by an operating system when switching tasks in certain cases; for example, if SLBE_C=0 is used for SLB translations shared between the tasks.
- 0b010 Preserve ERAT entries created when MSR_{IR/DR}=0. This value should generally be used by an operating system when switching tasks.
- 0b110 Preserve ERAT entries created when MSR_{HV}=1 and MSR_{IR/DR}=0. This value should be used by the hypervisor when switching partitions.

Programming Note

slbia serves as both a basic and an extended mnemonic. The Assembler will recognize an **slbia** mnemonic with one operand as the basic form, and an **slbia** mnemonic with no operand as the extended form. In the extended form the IH operand is omitted and assumed to be 0.

SLB Move To Entry**X-form**

slbmte RS, RB

0	31	RS	///	RB	402	/
	6	11	16	21	31	

The SLB entry specified by bits 52:63 of register RB is loaded from register RS and from the remainder of register RB. The contents of these registers are interpreted as shown in Figure 30.

RS

B	VSID	K _s K _p NLC	0	LP	0s
0	2	52	57	58	60 63

RB

SLB Find Entry ESID**X-form**

slbfee. RT, RB

0	31	RT	///	RB	979	1
	6	11	16	21	31	

The SLB is searched for an entry that matches the effective address specified by register RB. The search is performed as if it were being performed for purposes of address translation. E.g., in order for a given entry to satisfy the search, the entry must be valid ($V=1$), and $(RB)_{0:63-s}$ must equal $SLBE[ESID_{0:63-s}]$ (where 2^s is the segment size selected by the B field in the entry). If exactly one matching entry is found, the contents of the B, VSID, K_s , K_p , N, L, C, and LP fields of the entry are placed into register RT. If no matching entry is found, register RT is set to 0. If more than one matching entry is found, either one of the matching entries is used, as if it were the only matching entry, or a Machine Check occurs. If a Machine Check occurs, register RT, and CR Field 0 are set to undefined values, and the description below of how this register and this field is set does not apply.

The contents of registers RT and RB are interpreted as shown in Figure 33.

RT

B	VSID	$K_s K_p N L C$	0	LP	0s

 $RT_{58:59}$ LP
 $RT_{60:63}$ set to 0b0000
 $RB_{0:35}$ ESID
 $RB_{36:63}$ must be 0x00000000

Figure 33. GPR contents for slbfee.

If $s > 28$, $RT_{80-s:51}$ are set to zeros. On implementations that support a virtual address size of only n bits, $n < 78$, $RT_{2:79-n}$ are set to zeros.

CR Field 0 is set as follows. j is a 1-bit value that is equal to 0b1 if a matching entry was found. Otherwise, j is 0b0.

$$CR0_{LT GT EQ SO} = 0b00 \parallel j \parallel XER_{SO}$$

If this instruction is executed in 32-bit mode, $(RB)_{0:31}$ must be zeros (i.e., the ESID must be in the range 0-15).

This instruction is privileged.

Special Registers Altered:
CR0

5.9.3.2 Bridge to SLB Architecture [Category:Server.Phased-Out]

The facility described in this section can be used to ease the transition to the current Power ISA software-managed Segment Lookaside Buffer (SLB) architecture, from the Segment Register architecture provided by 32-bit PowerPC implementations. A complete description of the Segment Register architecture may be found in “Segmented Address Translation, 32-Bit Implementations,” Section 4.5, Book III of Version 1.10 of the PowerPC architecture, referenced in the introduction to this architecture.

The facility permits the operating system to continue to use the 32-bit PowerPC implementation’s *Segment Register Manipulation* instructions.

5.9.3.2.1 Segment Register Manipulation Instructions

The instructions described in this section -- *mtsr*, *mtsrin*, *mfsr*, and *mfsrin* -- allow software to associate effective segments 0 through 15 with any of virtual segments 0 through $2^{27}-1$. SLB entries 0:15 serve as virtual Segment Registers, with SLB entry *i* used to emulate Segment Register *i*. The *mtsr* and *mtsrin* instructions move 32 bits from a selected GPR to a selected SLB entry. The *mfsr* and *mfsrin* instructions move 32 bits from a selected SLB entry to a selected GPR.

The contents of the GPRs used by the instructions described in this section are shown in Figure 34. Fields shown as zeros must be zero for the *Move To Segment Register* instructions. Fields shown as hyphens are ignored. Fields shown as periods are ignored by the *Move To Segment Register* instructions and set to zero by the *Move From Segment Register* instructions. Fields shown as colons are ignored by the *Move To Segment Register* instructions and set to undefined values by the *Move From Segment Register* instructions.

RS/RT

RB

Figure 34. GPR contents for *mtsr*, *mtsrin*, *mfsr*, and *mfsrin*

Programming Note

The “Segment Register” format used by the instructions described in this section corresponds to the low-order 32 bits of RS and RT shown in the figure. This format is essentially the same as that for the Segment Registers of 32-bit PowerPC implementations. The only differences are the following.

- Bit 36 corresponds to a reserved bit in Segment Registers. Software must supply 0 for the bit because it corresponds to the L bit in SLB entries, and large pages are not supported for SLB entries created by the *Move To Segment Register* instructions.
- VSID bits 23:25 correspond to reserved bits in Segment Registers. Software can use these extra VSID bits to create VSIDs that are larger than those supported by the *Segment Register Manipulation* instructions of 32-bit PowerPC implementations.

Bit 32 of RS and RT corresponds to the T (direct-store) bit of early 32-bit PowerPC implementations. No corresponding bit exists in SLB entries.

Programming Note

The Programming Note in the introduction to Section 5.9.3.1 applies also to the *Segment Register Manipulation* instructions described in this section, and to any combination of the instructions described in the two sections, except as specified below for *mfsr* and *mfsrin*.

The requirement that the SLB contain at most one entry that translates a given effective address (see Section 5.7.6.1) applies to SLB entries created by *mtsr* and *mtsrin*. This requirement is satisfied naturally if only *mtsr* and *mtsrin* are used to create SLB entries for a given ESID, because for these instructions the association between SLB entries and ESID values is fixed (SLB entry *i* is used for ESID *i*). However, care must be taken if *slbmtc* is also used to create SLB entries for the ESID, because for *slbmtc* the association between SLB entries and ESID values is specified by software.

Move To Segment Register X-form

mtsr SR,RS

The SLB entry specified by SR is loaded from register RS, as follows.

SLBE Bit(s)	Set to	SLB Field(s)
0:31	0x0000_0000	ESID _{0:31}
32:35	SR	ESID _{32:35}
36	0b1	V
37:38	0b00	B
39:61	0b000110x0_0000	VSID _{0:22}
62:88	(RS) _{37:63}	VSID _{23:49}
89:91	(RS) _{33:35}	K _s K _p N
92	(RS) ₃₆	L ((RS) ₃₆ must be 0b0)

              (LPIDRLPID = (RS)32:63 ) ) )
    then
      if ((L = 0) | (b ≥ 20))
        then
          TLB entry ← invalid
        else
          if (entry_VA58:77-b = (RB)56:75-b)
            then
              TLB entry ← invalid

```

The operation performed by this instruction is based on the contents of registers RS and RB. The contents of these registers are shown below, where L is (RB)₆₃.

RS:

0s	LPID
0	32 63

RB if L=0:

AVA	0s	B	AP	0s	L
0	52	54	56	59	63

RB if L=1:

AVA	LP	0s	B	AVAL	L
0	44	52	54	56	63

RS_{32:63} contains an LPID value. The supported (RS)_{32:63} values are the same as the LPID values supported in LPIDR. RS_{0:31} must contain zeros and are ignored by the hardware.

If the L field in RB contains 0, the base page size is 4 KB and RB_{56:58} (AP - Actual Page size field) must be set to the SLBE_{LILP} encoding for the page size corresponding to the actual page size specified by the PTE that was used to create the TLB entry to be invalidated. Thus, b is equal to 12 and p is equal to log₂ (actual page size specified by (RB)_{56:58}). The Abbreviated Virtual Address (AVA) field in register RB must contain bits 14:65 of the virtual address translated by the TLB entry to be invalidated. Variable i is equal to 51.

If the L field in RB contains 1, the following rules apply.

- The base page size and actual page size are specified in the LP field in register RB, where the relationship between (RB)_{44:51} (LP - Large Page size selector field) and the base page size and actual page size is the same as the relationship between PTE_{LP} and the base page size and actual page size, except for the “r” bits (see Section 5.7.7.1 on page 782 and Figure 21 on page 783). Thus, b is equal to log₂ (base page size specified by (RB)_{44:51}) and p is equal to log₂ (actual page size specified by (RB)_{44:51}). Specifically, (RB)_{44+c:51} must be equal to the contents of bits c:7 of the LP field of the PTE that was used to create the TLB entry to be invalidated, where c is the maximum of 0 and (20-p).
- Variable i is the larger of (63-p) and the value that is the smaller of 43 and (63-b). (RB)_{0:i} must contain bits 14:(i+14) of the virtual address translated by the TLB to be invalidated. If b>20, RB_{64-b:43} may contain any value and are ignored by the hardware.
- If b<20, (RB)_{56:75-b} must contain bits 58:77-b of the virtual address translated by the TLB to be invalidated, and other bits in (RB)_{56:62} may contain any value and are ignored by the hardware.
- If b≥20, (RB)_{56:62} (AVAL - Abbreviated Virtual Address, Lower) may contain any value and are ignored by the hardware.

Let the segment size be equal to the segment size specified in (RB)_{54:55} (B field). The contents of RB_{54:55} must be the same as the contents of the B field of the PTE that was used to create the TLB entry to be invalidated.

RB_{52:53} and RB_{59:62} (when (RB)₆₃ = 0) must contain zeros and are ignored by the hardware.

All TLB entries on all threads that have all of the following properties are made invalid.

- The entry translates a virtual address for which all the following are true.
 - $VA_{14:14+i}$ is equal to $(RB)_{0:i}$.
 - $L=0$ or $b \geq 20$ or, if $L=1$ and $b < 20$, $VA_{58:77-b}$ is equal to $(RB)_{56:75-b}$.
- The segment size of the entry is the same as the segment size specified in $(RB)_{54:55}$.
- Either of the following is true:
 - The L field in RB is 0, the base page size of the entry is 4 KB, and the actual page size of the entry matches the actual page size specified in $(RB)_{56:58}$.
 - The L field in RB is 1, the base page size of the entry matches the base page size specified in $(RB)_{44:51}$, and the actual page size of the entry matches the actual page size specified in $(RB)_{44:51}$.
- Either of the following is true:
 - The implementation's TLB entries contain LPID values and $TLBE_{LPID} = (RS)_{32:63}$.
 - The implementation's TLB entries do not contain LPID values, and $LPIDR_{LPID} = (RS)_{32:63}$. The LPIDR used for this comparison is in the same thread as the TLB entry being tested.

If the implementation's TLB entries contain LPID values, additional TLB entries may also be made invalid if those TLB entries contain an LPID that matches $(RS)_{32:63}$. If the implementation's TLB entries do not contain LPID values, additional TLB entries may also be made invalid on any thread that is in the partition specified by $(RS)_{32:63}$.

MSR_{SF} must be 1 when this instruction is executed; otherwise the results are undefined.

If the value specified in $RS_{32:63}$, $RB_{54:55}$, $RB_{56:58}$ (when $RB_{63}=0$), or $RB_{44:51}$ (when $RB_{63}=1$) is not supported by the implementation, the instruction is treated as if the instruction form were invalid.

The operation performed by this instruction is ordered by the *eieio* (or *sync* or *ptesync*) instruction with respect to a subsequent *tlbsync* instruction executed by the thread executing the *tlbie* instruction. The operations caused by *tlbie* and *tlbsync* are ordered by *eieio* as a fourth set of operations, which is independent of the other three sets that *eieio* orders.

This instruction is hypervisor privileged.

See Section 5.10, "Page Table Update Synchronization Requirements" for a description of other requirements associated with the use of this instruction.

Special Registers Altered:

None

Programming Note

For *tlbie[!]* instructions in which $(RB)_{63}=0$, the AP value in RB is provided to make it easier for the hardware to locate address translations, in lookaside buffers, corresponding to the address translation being invalidated.

For *tlbie[!]* instructions the AP specification is not binary compatible with versions of the architecture that precede Version 2.06. As an example, for an actual page size of 64 KB $AP=0b101$, whereas software written for an implementation that precedes V. 2.06 would have $AP=100$ since AP was a 1 bit value followed by 0s in $RB_{57:58}$. If binary compatibility is important, for a 64 KB page software can use $AP=0b101$ on these earlier implementations since these implementations were required to ignore $RB_{57:58}$.

Programming Note

For *tlbie[!]* instructions the AVA and AVAL fields in RB contain different VA bits from those in PTE_{AVA} .

  else
    for each TLB entry in set (RB)i:51
      if (TLBEs do not contain LPID |
        (TLBEs contain LPID & (TLBELPID=LPIDRLPID)))
        then TLB entry ← invalid

```

The operation performed by this instruction is based on the contents of register RB. The contents of RB are shown below, where IS is (RB)_{52:53} and L is (RB)₆₃.

IS=0b00 and L=0:

0	AVA	IS	B	AP	Os	L
		52	54	56	59	63

IS=0b00 and L=1:

0	AVA	LP	IS	B	AVAL	L
		44	52	54	56	63

IS=0b10 or 0b11:

0	0s	SET	IS	0s	63
		40	52	54	

The Invalidation Selector (IS) field in RB has three defined values (0b00, 0b10, and 0b11). The IS value of 0b01 is reserved and is treated in the same manner as the corresponding case for instruction fields (see Section 1.3.3, “Reserved Fields and Reserved Values” on page 6 in Book I).

Engineering Note

IS field in RB contains 0b00

If the L field in RB contains 0, the base page size is 4 KB and RB_{56:58} (AP - Actual Page size field) must be set to the SLBE_{LILP} encoding for the page size corresponding to the actual page size specified by the PTE that was used to create the TLB entry to be invalidated. Thus, b is equal to 12 and p is equal to log₂(actual page size specified by (RB)_{56:58}). The Abbreviated Virtual Address (AVA) field in register RB must contain bits 14:65 of the virtual address translated by the TLB entry to be invalidated. Variable i is equal to 51.

If the L field in RB contains 1, the following rules apply.

- The base page size and actual page size are specified in the LP field in register RB, where the relationship between (RB)_{44:51} (LP - Large Page size selector field) and the base page size and actual page size is the same as the relationship between PTE_{LP} and the base page size and actual page size, except for the “r” bits (see Section 5.7.7.1 on page 782 and Figure 21 on page 783). Thus, b is equal to log₂(base page size specified by (RB)_{44:51}) and p is equal to log₂(actual page size specified by (RB)_{44:51}). Specifically, (RB)_{44+c:51} must be equal to the contents of bits c:7 of the LP field of the PTE that was used to create the TLB entry to be invalidated, where c is the maximum of 0 and (20-p).
- Variable i is the larger of (63-p) and the value that is the smaller of 43 and (63-b). (RB)_{0:i} must contain bits 14:(i+14) of the virtual address translated by the TLB to be invalidated. If b>20, RB_{64-b:43} may contain any value and are ignored by the hardware.
- If b<20, (RB)_{56:75-b} must contain bits 58:77-b of the virtual address translated by the TLB to be invalidated, and other bits in (RB)_{56:62} may

contain any value and are ignored by the hardware.

- If $b \geq 20$, $(RB)_{56:62}$ (AVAL - Abbreviated Virtual Address, Lower) may contain any value and are ignored by the hardware.

Let the segment size be equal to the segment size specified in $(RB)_{54:55}$ (B field). The contents of $RB_{54:55}$ must be the same as the contents of the B field of the PTE that was used to create the TLB entry to be invalidated.

Let the segment size be equal to the segment size specified in $(RB)_{54:55}$ (B field). The contents of $RB_{54:55}$ must be the same as the contents of PTE_B used to create the TLB entry to be invalidated.

All TLB entries that have all of the following properties are made invalid on the thread executing the *tlbiel* instruction.

- The entry translates a virtual address for which all the following are true:
 - $VA_{14:14+i}$ is equal to $(RB)_{0:i}$.
 - $L=0$ or $b \geq 20$ or, if $L=1$ and $b < 20$, $VA_{58:77-b}$ is equal to $(RB)_{56:75-b}$.
- The segment size of the entry is the same as the segment size specified in $(RB)_{54:55}$.
- Either of the following is true:
 - The L field in RB is 0, the base page size of the entry is 4 KB, and the actual page size of the entry matches the actual page size specified in $(RB)_{56:58}$.
 - The L field in RB is 1, the base page size of the entry matches the base page size specified in $(RB)_{44:51}$, and the actual page size of the entry matches the actual page size specified in $(RB)_{44:51}$.
- Either of the following is true:
 - The implementation's TLB entries do not contain LPID values.
 - The implementation's TLB entries contain LPID values and $TLBE_{LPID} = LPIDR_{LPID}$.

IS field in RB contains 0b10 or 0b11

$(RB)_{i:51}$ (bits $i-40:11$ of the SET field in (RB)) specify a set of TLB entries, where i is an implementation-dependent value in the range 40:51. Each entry in the set is invalidated if any of the following conditions are met for the entry.

- The implementation's TLB entries do not contain an LPID value.
- The IS field in RB contains 0b10 or $MSR_{HV}=0$, the implementation's TLB entries contain an LPID value, and $TLBE_{LPID} = LPIDR_{LPID}$.
- The IS field in RB contains 0b11 and $MSR_{HV}=1$.

How the TLB is divided into the 2^{52-i} sets is implementation-dependent. The relationship of virtual addresses to these sets is also implementation-dependent. However, if, in an implementation, there can be multiple TLB entries for the same vir-

tual address and same partition, then all these entries must be in a single set.

If the IS field in RB contains 0b10 or 0b11, it is implementation-dependent whether implementation-specific lookaside information that contains translations of effective addresses to real addresses is invalidated.

$RB_{0:39}$ (when $(RB)_{52:53} = 0b10$ or $0b11$), $RB_{59:62}$ (when $(RB)_{52:53} = 0b00$ and $(RB)_{63}=0$), and $RB_{54:63}$ (when $(RB)_{52:53} = 0b10$ or $0b11$) must contain 0s and are ignored by the hardware. When $i > 40$ and $(RB)_{52:53} = 0b10$ or $0b11$, $RB_{40:i-1}$ may contain any value and are ignored by the hardware.

Only TLB entries on the thread executing the *tlbiel* instruction are affected.

MSR_{SF} must be 1 when this instruction is executed; otherwise the results are boundedly undefined.

If the value specified in $RB_{54:55}$, $RB_{56:58}$ (when $RB_{52:53}=0b00$ and $(RB)_{63}$ is 0), or $RB_{44:51}$ (when $RB_{52:53}=0b00$ and $(RB)_{63}$ is 1) is not supported by the implementation, the instruction is treated as if the instruction form were invalid.

This instruction is privileged.

See Section 5.10, "Page Table Update Synchronization Requirements" on page 818 for a description of other requirements associated with the use of this instruction.

Special Registers Altered:

None

Programming Note

The primary use of this instruction by hypervisor software is to invalidate TLB entries prior to reassigning a thread to a new logical partition.

For IS = 0b10 or 0b11, it is implementation-dependent whether ERAT entries are invalidated. If the **tlbiel** instruction is being executed due to a partition swap, an **slbia** instruction can be used to invalidate the pertinent ERAT entries. If the **tlbiel** instruction is being executed to invalidate TLB entries with parity or ECC errors, the fact that the corresponding ERAT entries are not invalidated is immaterial. If the **tlbiel** instruction is being executed to invalidate multiple matching TLB entries, the fact that the corresponding ERAT entries are not invalidated is immaterial for implementations that never create multiple matching ERAT entries.

The primary use of this instruction by operating system software is to invalidate TLB entries that were created by the hypervisor using an implementation-specific hypervisor-managed TLB facility, if such a facility is provided.

tlbiel may be executed on a given thread even if the sequence **tlbie - eieio - tlbsync - ptesync** is concurrently being executed on another thread.

See also the Programming Notes with the description of the **tlbie** instruction.

TLB Invalidate All**X-form**

tlbia

0	31	///	///	///	370	/
	6		11	16	21	31

all TLB entries ← invalid

All TLB entries are made invalid on the thread executing the **tlbia** instruction.

This instruction is hypervisor privileged.

This instruction is optional, and need not be implemented.

Special Registers Altered:

None

Programming Note

tlbia does not affect TLBs on other threads.

TLB Synchronize**X-form**

tlbsync

31	///	///	///	566	/
0	6	11	16	21	31

The **tlbsync** instruction provides an ordering function for the effects of all **tlbie** instructions executed by the thread executing the **tlbsync** instruction, with respect to the memory barrier created by a subsequent **ptesync** instruction executed by the same thread. Executing a **tlbsync** instruction ensures that all of the following will occur.

- All TLB invalidations caused by **tlbie** instructions preceding the **tlbsync** instruction will have completed on any other thread before any data accesses caused by instructions following the **ptesync** instruction are performed with respect to that thread.
- All storage accesses by other threads for which the address was translated using the translations being invalidated, and all Reference and Change bit updates associated with address translations that were performed by other threads using the translations being invalidated, will have been performed with respect to the thread executing the **ptesync** instruction, to the extent required by the associated Memory Coherence Required attributes, before the **ptesync** instruction's memory barrier is created.

The operation performed by this instruction is ordered by the **eieio** (or **sync** or **ptesync**) instruction with respect to preceding **tlbie** instructions executed by the thread executing the **tlbsync** instruction. The operations caused by **tlbie** and **tlbsync** are ordered by **eieio** as a fourth set of operations, which is independent of the other three sets that **eieio** orders.

The **tlbsync** instruction may complete before operations caused by **tlbie** instructions preceding the **tlbsync** instruction have been performed.

This instruction is hypervisor privileged.

See Section 5.10 for a description of other requirements associated with the use of this instruction.

Special Registers Altered:

None

Programming Note

tlbsync should not be used to synchronize the completion of **tlbiel**.

5.10 Page Table Update Synchronization Requirements

This section describes rules that software must follow when updating the Page Table, and includes suggested sequences of operations for some representative cases.

In the sequences of operations shown in the following subsections, the Page Table Entry is assumed to be for a virtual page for which the base page size is equal to the actual page size. If these page sizes are different, multiple *tlbie* instructions are needed, one for each PTE corresponding to the virtual page.

In the sequences of operations shown in the following subsections, any alteration of a Page Table Entry (PTE) that corresponds to a single line in the sequence is assumed to be done using a *Store* instruction for which the access is atomic. Appropriate modifications must be made to these sequences if this assumption is not satisfied (e.g., if a store doubleword operation is done using two *Store Word* instructions).

Stores are not performed out-of-order, as described in Section 5.5, “Performing Operations Out-of-Order” on page 770. Moreover, address translations associated with instructions preceding the corresponding Store instructions are not performed again after the stores have been performed. (These address translations must have been performed before the store was determined to be required by the sequential execution model, because they might have caused an exception.) As a result, an update to a PTE need not be preceded by a context synchronizing operation.

All of the sequences require a context synchronizing operation after the sequence if the new contents of the PTE are to be used for address translations associated with subsequent instructions.

As noted in the description of the *Synchronize* instruction in Section 4.4.3 of Book II, address translation associated with instructions which occur in program order subsequent to the *Synchronize* (and this includes the *ptesync* variant) may be performed prior to the completion of the *Synchronize*. To ensure that these instructions and data which may have been speculatively fetched are discarded, a context synchronizing operation is required.

Programming Note

In many cases this context synchronization will occur naturally; for example, if the sequence is executed within an interrupt handler the *rfid* or *hrfid* instruction that returns from the interrupt handler may provide the required context synchronization.

Page Table Entries must not be changed in a manner that causes an implicit branch.

5.10.1 Page Table Updates

TLBs are non-coherent caches of the HTAB. TLB entries must be invalidated explicitly with one of the *TLB Invalidate* instructions.

Unsynchronized lookups in the HTAB continue even while it is being modified. Any thread, including a thread on which software is modifying the HTAB, may look in the HTAB at any time in an attempt to translate a virtual address. When modifying a PTE, software must ensure that the PTE’s V bit is 0 if the PTE is inconsistent (e.g., if the RPN field is not correct for the current AVA field).

Updates of Reference and Change bits by the hardware are not synchronized with the accesses that cause the updates. When modifying doubleword 1 of a PTE, software must take care to avoid overwriting a hardware update of these bits and to avoid having the value written by a *Store* instruction overwritten by a hardware update.

Software must execute *tlbie* and *tlbsync* instructions only as part of the following sequence, and must ensure that no other thread will execute a “conflicting instruction” while the instructions in the sequence are executing on the given thread.

tlbie instruction(s) specifying the same LPID operand and value
eieio
tlbsync
ptesync

Let L be the LPID value specified by the above *tlbie* instruction(s). The “conflicting instructions” in this case are the following.

- a *tlbie* instruction that specifies an LPID value that matches the value L
- a *tlbsync* instruction that is part of a *tlbie-eieio-tlbsync-ptesync* sequence in which the *tlbie* instruction(s) specify an LPID value that matches the value L
- an *mtspr* instruction that modifies the LPIDR, if the modification has either of the following properties.
 - The old LPID value (i.e., the contents of the LPIDR just before the *mtspr* instruction is executed) is the value L
 - The new LPID value (i.e., the value specified by the *mtspr* instruction) is the value L

Other instructions (excluding *mtspr* instructions that modify the LPIDR as described above, and excluding *tlbie* instructions except as shown) may be interleaved with the instruction sequence shown above, but the instructions in the sequence must appear in the order

shown. On systems consisting of only a single-threaded processor, the *eieio* and *tlbsync* instructions can be omitted.

Programming Note

The *eieio* instruction prevents the reordering of *tlbie* instructions previously executed with respect to the subsequent *tlbsync* instruction. The *tlbsync* instruction and the subsequent *ptesync* instruction together ensure that all storage accesses for which the address was translated using the translations being invalidated, and all Reference and Change bit updates associated with address translations that were performed using the translations being invalidated, will be performed with respect to any thread or mechanism, to the extent required by the associated Memory Coherence Required attributes, before any data accesses caused by instructions following the *ptesync* instruction are performed with respect to that thread or mechanism.

Before permitting an *mtspr* instruction that modifies the LPIDR to be executed on a given thread, software must ensure that no other thread will execute a “conflicting instruction” until after the *mtspr* instruction followed by a context synchronizing instruction have been executed on the given thread (a context synchronizing event can be used instead of the context synchronizing instruction; see Chapter 10).

The “conflicting instructions” in this case are the following.

- a *tlbie* instruction specifying an LPID operand value that matches either the old or the new $\text{LPIDR}_{\text{LPID}}$ value
- a *tlbsync* instruction that is part of a *tlbie-eieio-tlbsync-ptesync* sequence in which the *tlbie* instruction(s) specify an LPID value that matches either the old or the new $\text{LPIDR}_{\text{LPID}}$ value

Programming Note

The restrictions specified above regarding modifying the LPIDR apply even on systems consisting of only a single-threaded processor, and even if the new LPID value is equal to the old LPID value.

The sequences of operations shown in the following subsections assume a multi-threaded environment. In an environment consisting of only a single-threaded processor, the *tlbsync* must be omitted, and the *eieio* that separates the *tlbie* from the *tlbsync* can be omitted. In a multi-threaded environment, when *tblie* is used instead of *tlbie* in a Page Table update, the synchronization requirements are the same as when *tlbie*

is used in an environment consisting of only a single-threaded processor.

Programming Note

For all of the sequences shown in the following subsections, if it is necessary to communicate completion of the sequence to software running on another thread, the *ptesync* instruction at the end of the sequence should be followed by a *Store* instruction that stores a chosen value to some chosen storage location X. The memory barrier created by the *ptesync* instruction ensures that if a *Load* instruction executed by another thread returns the chosen value from location X, the sequence’s stores to the Page Table have been performed with respect to that other thread. The *Load* instruction that returns the chosen value should be followed by a context synchronizing instruction in order to ensure that all instructions following the context synchronizing instruction will be fetched and executed using the values stored by the sequence (or values stored subsequently). (These instructions may have been fetched or executed out-of-order using the old contents of the PTE.)

This Note assumes that the Page Table and location X are in storage that is Memory Coherence Required.

5.10.1.1 Adding a Page Table Entry

This is the simplest Page Table case. The V bit of the old entry is assumed to be 0. The following sequence can be used to create a PTE, maintain a consistent state, and ensure that a subsequent reference to the virtual address translated by the new entry will use the correct real address and associated attributes

```

PTEARPN,LP,AC,R,C,WIMG,N,PP ← new values
eieio /* order 1st update before 2nd */
PTEB,AVA,SW,L,H,V ← new values (V=1)
ptesync /* order updates before next
        Page Table search and before
        next data access */

```

5.10.1.2 Modifying a Page Table Entry

General Case

If a valid entry is to be modified and the translation instantiated by the entry being modified is to be invalidated, the following sequence can be used to modify the PTE, maintain a consistent state, ensure that the translation instantiated by the old entry is no longer available, and ensure that a subsequent reference to the virtual address translated by the new entry will use the correct real address and associated attributes. (The sequence is equivalent to deleting the PTE and then adding a new one; see Sections 5.10.1.1 and 5.10.1.3.)

```
PTEV ← 0 /* (other fields don't matter) */
ptesync /* order update before tlbie and
         before next Page Table search */
tlbie(old_B,old_VA14:77-b,old_L,old_LP,old_AP,
      old_LPID) /*invalidate old translation*/
eieio /* order tlbie before tlbsync */
tlbsync /* order tlbie before ptesync */
ptesync /* order tlbie, tlbsync and 1st
         update before 2nd update */
PTEARN,LP,AC,R,C,WIMG,N,PP ← new values
eieio /* order 2nd update before 3rd */
PTEB,AVA,SW,L,H,V ← new values (V=1)
ptesync /* order 2nd and 3rd updates before
         next Page Table search and
         before next data access */
```

Resetting the Reference Bit

If the only change being made to a valid entry is to set the Reference bit to 0, a simpler sequence suffices because the Reference bit need not be maintained exactly.

```
oldR ← PTER /* get old R */
if oldR = 1 then
  PTER ← 0 /* store byte (R=0, other bits
            unchanged) */
tlbie(B,VA14:77-b,L,LP,AP,LPID) /* invalidate
                                entry */
eieio /* order tlbie before tlbsync */
tlbsync /* order tlbie before ptesync */
ptesync /* order tlbie, tlbsync, and update
         before next Page Table search
         and before next data access */
```

Modifying the SW field

If the only change being made to a valid entry is to modify the SW field, the following sequence suffices, because the SW field is not used by the hardware and doubleword 0 of the PTE is not modified by the hardware.

```
loop: ldarx r1 ← PTE_dwd_0 /* load dwd 0 of PTE */
      r157:60 ← new SW value /* replace SW, in r1 */
      stdcx. PTE_dwd_0 ← r1 /* store dwd 0 of PTE
        if still reserved (new SW value, other
        fields unchanged) */
      bne- loop /* loop if lost reservation */
```

A *lbarx/stbcx.*, *lharx/sthcx.*, or *lwarx/stwcx.* pair (specifying the low-order byte, halfword, or word respectively of doubleword 0 of the PTE) can be used instead of the *ldarx/stdcx.* pair shown above.

Modifying the Virtual Address

If the virtual address translated by a valid PTE is to be modified and the new virtual address hashes to the same PTEG (or the same two PTEGs if the secondary Page Table search is enabled) as does the old virtual address, the following sequence can be used to modify the PTE, maintain a consistent state, ensure that the translation instantiated by the old entry is no longer available, and ensure that a subsequent reference to the virtual address translated by the new entry will use the correct real address and associated attributes.

```
PTEAVA,SW,L,H,V ← new values (V=1)
ptesync /* order update before tlbie and
         before next Page Table search */
tlbie(old_B,old_VA14:77-b,old_L,old_LP,old_AP,
      old_LPID) /*invalidate old translation*/
eieio /* order tlbie before tlbsync */
tlbsync /* order tlbie before ptesync */
ptesync /* order tlbie, tlbsync, and update
         before next data access */
```

5.10.1.3 Deleting a Page Table Entry

The following sequence can be used to ensure that the translation instantiated by an existing entry is no longer available.

```
PTEV ← 0 /* (other fields don't matter) */
ptesync /* order update before tlbie and
         before next Page Table search */
tlbie(old_B,old_VA14:77-b,old_L,old_LP,old_AP,
      old_LPID) /*invalidate old translation*/
eieio /* order tlbie before tlbsync */
tlbsync /* order tlbie before ptesync */
ptesync /* order tlbie, tlbsync, and update
         before next data access */
```

6.5.6 Instruction Segment Interrupt	834		

6.1 Overview

The Power ISA provides an interrupt mechanism to allow the thread to change state as a result of external signals, errors, or unusual conditions arising in the execution of instructions.

System Reset and Machine Check interrupts are not ordered. All other interrupts are ordered such that only

one interrupt is reported, and when it is processed (taken) no program state is lost. Since Save/Restore Registers SRR0 and SRR1 are serially reusable resources used by most interrupts, program state may be lost when an unordered interrupt is taken.

6.2 Interrupt Registers

6.2.1 Machine Status Save/Restore Registers

When various interrupts occur, the state of the machine is saved in the Machine Status Save/Restore registers (SRR0 and SRR1). Section 6.5 describes which registers are altered by each interrupt.

Figure 35. Save/Restore Registers

SRR1 bits may be treated as reserved in a given implementation if they correspond to MSR bits that are reserved or are treated as reserved in that implementation and, for SRR1 bits in the range 33:36, 42:43, and 45:47, they are specified as being set either to 0 or to an undefined value for all interrupts that set SRR1 (including implementation-dependent setting, e.g. by the Machine Check interrupt or by implementation-specific interrupts). SRR1₄₄ cannot be treated as reserved, regardless of how it is set by interrupts, because it is used by software, as described in a Programming Note near the end of Section 6.5.9, “Program Interrupt” on page 837.

6.2.2 Hypervisor Machine Status Save/Restore Registers

When various interrupts occur, the state of the machine is saved in the Hypervisor Machine Status Save/Restore registers (HSRR0 and HSRR1). Section 6.5 describes which registers are altered by each interrupt.

Figure 36. Hypervisor Save/Restore Registers

HSRR1 bits may be treated as reserved in a given implementation if they correspond to MSR bits that are reserved or are treated as reserved in that implementation and, for HSRR1 bits in the range 33:36 and 42:47, they are specified as being set either to 0 or to an undefined value for all interrupts that set HSRR1 (including implementation-dependent setting, e.g. by implementation-specific interrupts).

The HSRR0 and HSRR1 are hypervisor resources; see Chapter 2.

Programming Note

Execution of some instructions, and fetching instructions when MSR_{IR}=1, may have the side effect of modifying HSRR0 and HSRR1; see Section 6.4.4.

6.2.3 Data Address Register

The Data Address Register (DAR) is a 64-bit register that is set by the Machine Check, Data Storage, Data Segment, and Alignment interrupts; see Sections 6.5.2, 6.5.3, 6.5.4, and 6.5.8. In general, when one of these interrupts occurs the DAR is set to an effective address associated with the storage access that caused the interrupt, with the high-order 32 bits of the DAR set to 0 if the interrupt occurs in 32-bit mode.

Figure 37. Data Address Register

6.2.4 Hypervisor Data Address Register

The Hypervisor Data Address Register (HDAR) is a 64-bit register that is set by the Hypervisor Data Storage Interrupt; see Section 6.5.15. In general, when this interrupt occurs, the HDAR is set to an effective address associated with the storage access that caused the interrupt, with the high-order 32 bits of the HDAR set to 0 if the interrupt occurs in 32-bit mode.

Figure 38. Hypervisor Data Address Register

6.2.5 Data Storage Interrupt Status Register

The Data Storage Interrupt Status Register (DSISR) is a 32-bit register that is set by the Machine Check, Data Storage, Data Segment, and Alignment interrupts; see Sections 6.5.2, 6.5.3, 6.5.4, and 6.5.8. In general, when one of these interrupts occurs the DSISR is set to indicate the cause of the interrupt.

Figure 39. Data Storage Interrupt Status Register

DSISR bits may be treated as reserved in a given implementation if they are specified as being set either to 0 or to an undefined value for all interrupts that set the DSISR (including implementation-dependent set-

ting, e.g. by the Machine Check interrupt or by implementation-specific interrupts).

6.2.6 Hypervisor Data Storage Interrupt Status Register

The Hypervisor Data Storage Interrupt Status Register (HDSISR) is a 32-bit register that is set by the Hypervisor Data Storage interrupt. In general, when one of these interrupts occurs the HDSISR is set to indicate the cause of the interrupt.

Figure 40. Hypervisor Data Storage Interrupt Status Register

6.2.7 Hypervisor Emulation Instruction Register

The Hypervisor Emulation Instruction Register (HEIR) is a 32-bit register that is set by the Hypervisor Emulation Assistance interrupt; see Section 6.5.17. The image of the instruction that caused the interrupt is loaded into the register.

Figure 41. Hypervisor Emulation Instruction Register

6.2.8 Hypervisor Maintenance Exception Register

Each bit in the Hypervisor Maintenance Exception Register (HMER) is associated with one or more causes of the Hypervisor Maintenance exception, and is set when the associated exception(s) occur. If the corresponding bit in the Hypervisor Maintenance Exception Enable Register (HMEER) is set, a Hypervisor Maintenance Interrupt (HMI) may occur. If the thread is in a power-saving mode when the interrupt would have occurred, the thread will exit the power-saving mode; see Section 6.5.18 and Section 3.3.2.

Figure 42. Hypervisor Maintenance Exception Register

The contents of the HMER are as follows:

- 0 Set to 1 for a Malfunction Alert.
- 1 Set to 1 when performance is degraded for thermal reasons.
- 2 Set to 1 when thread recovery is invoked.

Others Implementation-specific.

When the *mtspr* instruction is executed with the HMER as the encoded Special Purpose Register, the contents of register RS are ANDed with the contents of the HMER and the result is placed into the HMER.

The exception bits in the HMER are sticky; that is, once set to 1 they remain set to 1 until they are set to 0 by an *mtmmer* instruction.

Programming Note

An access to the HMER is likely to be very slow. Software should access it sparingly.

6.2.9 Hypervisor Maintenance Exception Enable Register

The Hypervisor Maintenance Exception Enable Register (HMEER) is a 64-bit register in which each bit enables the corresponding exception in the HMER to cause the Hypervisor Maintenance interrupt, potentially causing exit from power-saving mode; see Section 6.5.18 and Section 3.3.2.

Figure 43. Hypervisor Maintenance Exception Enable Register

6.3 Interrupt Synchronization

When an interrupt occurs, SRR0 or HSRR0 is set to point to an instruction such that all preceding instructions have completed execution, no subsequent instruction has begun execution, and the instruction addressed by SRR0 or HSRR0 may or may not have completed execution, depending on the interrupt type.

With the exception of System Reset and Machine Check interrupts, all interrupts are context synchronizing as defined in Section 1.5.1. System Reset and Machine Check interrupts are context synchronizing if they are recoverable (i.e., if bit 62 of SRR1 is set to 1 by the interrupt). If a System Reset or Machine Check interrupt is not recoverable (i.e., if bit 62 of SRR1 is set to 0 by the interrupt), it acts like a context synchronizing operation with respect to subsequent instructions. That is, a non-recoverable System Reset or Machine Check interrupt need not satisfy items 1 through 3 of Section 1.5.1, but does satisfy items 4 and 5.

6.4 Interrupt Classes

Interrupts are classified by whether they are directly caused by the execution of an instruction or are caused by some other system exception. Those that are “system-caused” are:

- System Reset
- Machine Check
- External
- Decrementer
- Hypervisor Decrementer
- Hypervisor Maintenance

External, Decrementer, Hypervisor Decrementer, and Hypervisor Maintenance interrupts are maskable interrupts. Therefore, software may delay the generation of these interrupts. System Reset and Machine Check interrupts are not maskable.

“Instruction-caused” interrupts are further divided into two classes, *precise* and *imprecise*.

6.4.1 Precise Interrupt

Except for the Imprecise Mode Floating-Point Enabled Exception type Program interrupt, all instruction-caused interrupts are precise.

When the fetching or execution of an instruction causes a precise interrupt, the following conditions exist at the interrupt point.

1. SRR0 addresses either the instruction causing the exception or the immediately following instruction. Which instruction is addressed can be determined from the interrupt type and status bits.
2. An interrupt is generated such that all instructions preceding the instruction causing the exception

appear to have completed with respect to the executing thread.

3. The instruction causing the exception may appear not to have begun execution (except for causing the exception), may have been partially executed, or may have completed, depending on the interrupt type.
4. Architecturally, no subsequent instruction has begun execution.

6.4.2 Imprecise Interrupt

This architecture defines one imprecise interrupt, the Imprecise Mode Floating-Point Enabled Exception type Program interrupt.

When an Imprecise Mode Floating-Point Enabled Exception type Program interrupt occurs, the following conditions exist at the interrupt point.

1. SRR0 addresses either the instruction causing the exception or some instruction following that instruction; see Section 6.5.9, “Program Interrupt” on page 837.
2. An interrupt is generated such that all instructions preceding the instruction addressed by SRR0 appear to have completed with respect to the executing thread.
3. The instruction addressed by SRR0 may appear not to have begun execution (except, in some cases, for causing the interrupt to occur), may have been partially executed, or may have completed; see Section 6.5.9.
4. No instruction following the instruction addressed by SRR0 appears to have begun execution.

All Floating-Point Enabled Exception type Program interrupts are maskable using the MSR bits FE0 and FE1. Although these interrupts are maskable, they differ significantly from the other maskable interrupts in that the masking of these interrupts is usually controlled by the application program, whereas the masking of all other maskable interrupts is controlled by either the operating system or the hypervisor.

6.4.3 Interrupt Processing

Associated with each kind of interrupt is an *interrupt vector*, which contains the initial sequence of instructions that is executed when the corresponding interrupt occurs.

Interrupt processing consists of saving a small part of the thread's state in certain registers, identifying the cause of the interrupt in other registers, and continuing execution at the corresponding interrupt vector location. When an exception exists that will cause an interrupt to be generated and it has been determined that the interrupt will occur, the following actions are performed. The handling of Machine Check interrupts (see Section 6.5.2) differs from the description given below in several respects.

1. SRR0 or HSRR0 is loaded with an instruction address that depends on the type of interrupt; see the specific interrupt description for details.
2. Bits 33:36 and 42:47 of SRR1 or HSRR1 are loaded with information specific to the interrupt type.
3. Bits 0:32, 37:41, and 48:63 of SRR1 or HSRR1 are loaded with a copy of the corresponding bits of the MSR.
4. The MSR is set as shown in Figure 44 on page 828. In particular, MSR bits IR and DR are set to 0, disabling relocation, and MSR bit SF is set to 1, selecting 64-bit mode. The new values take effect beginning with the first instruction executed following the interrupt.
5. Instruction fetch and execution resumes, using the new MSR value, at the effective address specific to the interrupt type. These effective addresses are shown in Figure 45 on page 829.

Interrupts do not clear reservations obtained with *lbarx*, *lharx*, *lwarx*, or *ldarx*.

Programming Note

In general, when an interrupt occurs, the following instructions should be executed by the operating system before dispatching a “new” program.

- *stbcx.*, *sthcx.*, *stwcx.*, or *stdcx.*, to clear the reservation if one is outstanding, to ensure that a *lbarx*, *lharx*, *lwarx*, or *ldarx* in the interrupted program is not paired with a *stbcx.*, *sthcx.*, *stwcx.*, or *stdcx.* in the “new” program.
- *sync*, to ensure that all storage accesses caused by the interrupted program will be performed with respect to another thread before the program is resumed on that other thread.
- *isync* or *rfid*, to ensure that the instructions in the “new” program execute in the “new” context.

Programming Note

For instruction-caused interrupts, in some cases it may be desirable for the operating system to emulate the instruction that caused the interrupt, while in other cases it may be desirable for the operating system not to emulate the instruction. The following list, while not complete, illustrates criteria by which decisions regarding emulation should be made. The list applies to general execution environments; it does not necessarily apply to special environments such as program debugging, bring-up, etc.

In general, the instruction should be emulated if:

- The interrupt is caused by a condition for which the instruction description (including related material such as the introduction to the section describing the instruction) implies that the instruction works correctly. Example: Alignment interrupt caused by *lmw* for which the storage operand is not aligned, or by *dcbz* for which the storage operand is in storage that is Write Through Required or Caching Inhibited.
- The instruction is an illegal instruction that should appear, to the program executing it, as if it were supported by the implementation. Example: A Hypervisor Emulation Assistance interrupt is caused by an instruction that has been phased out of the architecture but is still used by some programs that the operating system supports, or by an instruction that is in

a category that the implementation does not support but is used by some programs that the operating system supports.

In general, the instruction should not be emulated if:

- The purpose of the instruction is to cause an interrupt. Example: System Call interrupt caused by *sc*.
- The interrupt is caused by a condition that is stated, in the instruction description, potentially to cause the interrupt. Example: Alignment interrupt caused by *lwarx* for which the storage operand is not aligned.
- The program is attempting to perform a function that it should not be permitted to perform. Example: Data Storage interrupt caused by *lwz* for which the storage operand is in storage that the program should not be permitted to access. (If the function is one that the program should be permitted to perform, the conditions that caused the interrupt should be corrected and the program re-dispatched such that the instruction will be re-executed. Example: Data Storage interrupt caused by *lwz* for which the storage operand is in storage that the program should be permitted to access but for which there currently is no PTE that satisfies the Page Table search.)

Programming Note

If a program modifies an instruction that it or another program will subsequently execute and the execution of the instruction causes an interrupt, the state of storage and the content of some registers may appear to be inconsistent to the interrupt handler program. For example, this could be the result of one program executing an instruction that causes a Hypervisor Emulation Assistance interrupt just before another instance of the same program stores an *Add Immediate* instruction in that storage location. To the interrupt handler code, it would appear that a hardware generated the interrupt as the result of executing a valid instruction.

Programming Note

In order to handle Machine Check and System Reset interrupts correctly, the operating system should manage MSR_{RI} as follows.

- In the Machine Check and System Reset interrupt handlers, interpret SRR1 bit 62 (where MSR_{RI} is placed) as:
 - 0: interrupt is not recoverable
 - 1: interrupt is recoverable
- In each interrupt handler, when enough state has been saved that a Machine Check or System Reset interrupt can be recovered from, set MSR_{RI} to 1.
- In each interrupt handler, do the following (in order) just before returning.
 1. Set MSR_{RI} to 0.
 2. Set SRR0 and SRR1 to the values to be used by *rfid*. The new value of SRR1 should have bit 62 set to 1 (which will happen naturally if SRR1 is restored to the value saved there by the interrupt, because the interrupt handler will not be executing this sequence unless the interrupt is recoverable).
 3. Execute *rfid*.

For interrupts that set the SRRs other than Machine Check or System Reset, MSR_{RI} can be managed similarly when these interrupts occur within interrupt handlers for other interrupts that set the SRRs.

This Note does not apply to interrupts that set the HSRRs because these interrupts put the thread into hypervisor state, and either do not occur or can be prevented from occurring within interrupt handlers for other interrupts that set the HSRRs.

6.4.4 Implicit alteration of HSRR0 and HSRR1

Executing some of the more complex instructions may have the side effect of altering the contents of HSRR0 and HSRR1. The instructions listed below are guaranteed not to have this side effect. Any omission of instruction suffixes is significant; e.g., *add* is listed but *add.* is excluded.

1. *Branch* instructions

b[l][a], *bc[l][a]*, *bclrl[l]*, *bcctr[l]*

2. *Fixed-Point Load and Store* Instructions

lbz, *lbzx*, *lhz*, *lhzx*, *lwz*, *lwzx*, *ld<64>*, *ldx<64>*,
stb, *stbx*, *sth*, *sthx*, *stw*, *stwx*, *std<64>*,
stdx<64>

Execution of these instructions is guaranteed not to have the side effect of altering HSRR0 and HSRR1 only if the storage operand is aligned and MSR_{DR}=0.

3. *Arithmetic* instructions

addi, *addis*, *add*, *subf*, *neg*

4. *Compare* instructions

cmpi, *cmp*, *cmpli*, *cmpl*

5. *Logical and Extend Sign* instructions

ori, *oris*, *xori*, *xoris*, *and*, *or*, *xor*, *nand*, *nor*,
eqv, *andc*, *orc*, *extsb*, *extsh*, *extsw*

6. *Rotate and Shift* instructions

rldicl<64>, *rldicr<64>*, *rldic<64>*, *rlwinm*,
rldcl<64>, *rldcr<64>*, *rlwnm*, *rldimi<64>*, *rlwimi*,
sld<64>, *slw*, *srd<64>*, *srw*

7. Other instructions

isync

rfid, *hrfid*

mtspr, *mfspr*, *mtmsrd*, *mfmshr*

Programming Note

Instructions excluded from the list include the following.

- instructions that set or use XER_{CA}
- instructions that set XER_{OV} or XER_{SO}
- *andi.*, *andis.*, and fixed-point instructions with Rc=1 (Fixed-point instructions with Rc=1 can be replaced by the corresponding instruction with Rc=0 followed by a *Compare* instruction.)
- all floating-point instructions
- *mftb*

These instructions, and the other excluded instructions, may be implemented with the assistance of the Hypervisor Emulation Assistance interrupt, or of implementation-specific interrupts that modify HSRR0 and HSRR1. The included instructions are guaranteed not to be implemented thus. (The included instructions are sufficiently simple as to be unlikely to need such assistance. Moreover, they are likely to be needed in interrupt handlers before HSRR0 and HSRR1 have been saved or after HSRR0 and HSRR1 have been restored.)

Similarly, fetching instructions may have the side effect of altering the contents of HSRR0 and HSRR1 unless MSR_{IR}=0.

6.5 Interrupt Definitions

Figure 44 shows all the types of interrupts and the values assigned to the MSR for each. Figure 45 shows the

effective address of the interrupt vector for each interrupt type. (Section 5.7.4 on page 777 summarizes all architecturally defined uses of effective addresses, including those implied by Figure 45.)

Interrupt Type	MSR Bit							
	IR	DR	FE0	FE1	EE	RI	ME	HV
System Reset	0	0	0	0	0	0	p	1
Machine Check	0	0	0	0	0	0	0	1
Data Storage	0	0	0	0	0	0	-	m

Figure 45. Effective address of interrupt vector by interrupt type

Programming Note

When address translation is disabled, use of any of the effective addresses that are shown as reserved in Figure 45 risks incompatibility with future implementations.

6.5.1 System Reset Interrupt

If a System Reset exception causes an interrupt that is not context synchronizing or causes the loss of a Machine Check exception or a Direct External exception, or if the state of the thread has been corrupted, the interrupt is not recoverable.

When the thread is in any power-saving level, a System Reset interrupt occurs when a System Reset exception exists. When the thread is in doze or nap power-saving levels, a System Reset interrupt occurs when any of the following exceptions exists provided that the exception is enabled to cause exit from power saving mode (see Section 2.2, “Logical Partitioning Control Register (LPCR)”). When the thread is in sleep or rvwinkle power-saving level, it is implementation-specific whether the following exceptions, when enabled, cause exit, or whether only a system-reset causes exit.

- External
- Decrementer
- Hypervisor Maintenance
- Implementation-specific

SRR1 indicates the exception that caused exit from power-saving mode as specified below.

The following registers are set:

SRR0 If the interrupt did not occur when the thread was in power-saving mode, set to the effective address of the instruction that the thread would have attempted to execute next if no interrupt conditions were present; otherwise, set to an undefined value.

SRR1
33:36 Set to 0.
42:44 If the interrupt did not occur when the thread was in power-saving mode, set to an implementation-specific value. If the interrupt occurred when the thread was in power-saving mode, set to indicate the exception that caused exit from power-saving mode as shown below:

SRR1 _{42:44}	Exception
000	Reserved
001	Implementation specific
010	System Reset
011	Decrementer
100	External
101	Hypervisor Maintenance
110	Implementation specific
111	Implementation specific

If multiple exceptions that cause exit from power-saving mode exist, the exception

reported is the exception corresponding to the interrupt that would have occurred if the same exceptions existed and the thread was not in power-saving mode.

45 Set to 0.

46:47 Set to indicate whether the interrupt occurred when the thread was in power-saving mode and, if so, the extent to which resource state was maintained while the thread was in power-saving mode, as follows:

00 The interrupt did not occur when the thread was in power-saving mode.

01 The interrupt occurred when the thread was in power-saving mode. The state of all resources was maintained as if the thread was not in power-saving mode.

10 The interrupt occurred when the thread was in power-saving mode. The state of some resources was not maintained, but the state of all hypervisor resources was maintained as if the thread was not in power-saving mode and the state of all other resources is such that the hypervisor can resume execution.

11 The interrupt occurred when the thread was in power-saving mode. The state of some resources was not maintained, and the state of some hypervisor resources was not maintained or the state of some resources is such that the hypervisor cannot resume execution.

Programming Note

Although the resources that are maintained in power-saving mode (except in doze power-saving level) are implementation-dependent, the hypervisor can avoid implementation-dependence in the portion of the System Reset and Machine Check interrupt handlers that recover from having been in power-saving mode by using the contents of `SRR146:47`, to determine what state to restore. (To avoid implementation-dependence in the portion of the hypervisor that enters power-saving mode, the hypervisor must use the specification of the four instructions to determine what state to save.)

62 If the interrupt did not occur while the thread was in power-saving mode, loaded from bit 62 of the MSR if the thread is in a recoverable state; otherwise set to 0. If the interrupt occurred while the thread was in power-saving mode, set to 1 if the thread is in a recoverable state; otherwise set to 0.

Others Loaded from the MSR.

MSR See Figure 44 on page 828.

In addition, if the interrupt occurs when the thread is in power-saving mode and is caused by an exception other than a System Reset exception, all other registers, except `HSRR0` and `HSRR1`, that would be set by the corresponding interrupt if the exception occurred when the thread was not in power-saving mode are set by the System Reset interrupt, and are set to the values to which they would be set if the exception occurred when the thread was not in power-saving mode.

Execution resumes at effective address `0x0000_0000_0000_0100`.

The means for software to distinguish between power-on Reset and other types of System Reset are implementation-dependent.

6.5.2 Machine Check Interrupt

The causes of Machine Check interrupts are implementation-dependent. For example, a Machine Check interrupt may be caused by a reference to a storage location that contains an uncorrectable error or does not exist (see Section 5.6), or by an error in the storage subsystem.

When the thread is not in power-saving mode, Machine Check interrupts are enabled when `MSRME=1`; if `MSRME=0` and a Machine Check exception occurs, the thread enters the Checkstop state. When the thread is in doze or nap power-saving levels, Machine Check interrupts are treated as enabled when `LPCRPECE[2]=1` and cannot occur when `LPCRPECE[2]=0`. When the thread is in sleep or rwinkle power-saving level, it is implementation-specific whether Machine Check interrupts are treated as enabled under the same conditions as in doze and nap power-saving level or if they cannot occur. If a Machine Check exception occurs while the thread is in power-saving mode and the Machine Check exception is not enabled to cause exit from power-saving mode, the result is implementation specific.

The Checkstop state may also be entered if an access is attempted to a storage location that does not exist (see Section 5.6), or if an implementation-dependant hardware error occurs that prevents continued operation.

Disabled Machine Check (Checkstop State)

When a thread is in Checkstop state, instruction processing is suspended and generally cannot be restarted without resetting the thread. Some implementations may preserve some or all of the internal state of the thread when entering Checkstop state, so that the state can be analyzed as an aid in problem determination.

Enabled Machine Check

If a Machine Check exception causes an interrupt that is not context synchronizing or causes the loss of a Direct External exception, or if the state of the thread has been corrupted, the interrupt is not recoverable.

In some systems, the operating system may attempt to identify and log the cause of the Machine Check.

The following registers are set:

SRR0 If the interrupt did not occur while the thread was in power-saving mode, set on a "best effort" basis to the effective address of some instruction that was executing or was about to be executed when the Machine Check exception occurred; otherwise set to an undefined value.

Programming Note

Since the hypervisor can save the address of the instruction following the power-saving mode instruction if needed, there is no need for the thread to preserve it and store it into SRR0. Therefore, for ease of implementation, the contents of SRR0 upon exit from power-saving mode are specified to be undefined.

SRR1

46:47

Set to indicate whether the interrupt occurred when the thread was in power-saving mode and, if so, the extent to which resource state was maintained while the thread was in power-saving mode, as follows.

- 00 The interrupt did not occur when the thread was in power-saving mode.
- 01 The interrupt occurred when the thread was in power-saving mode. The state of all resources was maintained as if the thread was not in power-saving mode.

10 The interrupt occurred when the thread was in power-saving mode. The state of some resources was not maintained, but the state of all hypervisor resources was maintained as if the thread was not in power-saving mode and the state of all other resources is such that the hypervisor can resume execution.

11 The interrupt occurred when the thread was in power-saving mode. The state of some resources was not maintained, and the state of some hypervisor resources was not maintained or the state of some resources is such that the hypervisor cannot resume execution.

Programming Note

Although the resources that are maintained in power-saving mode (except in the doze power-saving level) are implementation-dependent, the hypervisor can avoid implementation-dependence in the portion of the System Reset and Machine Check interrupt handlers that recover from having been in power-saving mode by using the contents of SRR1^{46:47} to determine what state to restore. (To avoid implementation-dependence in the portion of the hypervisor that enters power-saving mode, the hypervisor must use the specification of the four instructions to determine what state to save.)

62 If the interrupt did not occur while the thread was in power-saving mode, loaded from bit 62 of the MSR if the thread is in a recoverable state; otherwise set to 0. If the interrupt occurred while the thread was in power-saving mode, set to 1 if the thread is in a recoverable state; otherwise set to 0.

Others Set to an implementation-dependent value.

MSR See Figure 44.

DSISR Set to an implementation-dependent value.

DAR Set to an implementation-dependent value.

Execution resumes at effective address 0x0000_0000_0000_0200.

A Machine Check interrupt caused by the existence of multiple SLB entries or TLB entries (or similar entries in implementation-specific translation caches) which translate a given effective or virtual address (see Sec-

tions 5.7.6.2 and 5.7.7.3.) must occur while still in the context of the partition that caused it. The interrupt must be presented in a way that permits continuing execution, with damage limited to the causing partition. Treating the exception as instruction-caused will achieve these requirements.

Programming Note

If a Machine Check interrupt is caused by an error in the storage subsystem, the storage subsystem may return incorrect data, which may be placed into registers. This corruption of register contents may occur even if the interrupt is recoverable.

6.5.3 Data Storage Interrupt

A Data Storage interrupt occurs when no higher priority exception exists, the value of the expression

$$(MSR_{HV\ PR} = 0b10) \mid (\neg VPM_0 \ \& \ \neg MSR_{DR}) \\ \mid (\neg VPM_1 \ \& \ MSR_{DR})$$

is 1, and a data access cannot be performed for any of the following reasons.

- Data address translation is enabled ($MSR_{DR}=1$) and the virtual address of any byte of the storage location specified by a *Load*, *Store*, *icbi*, *dcbz*, *dcbst*, *dcbfl*, *eciwx*, or *ecowx* instruction cannot be translated to a real address.
- The effective address specified by a *lq*, *stq*, *lbarx*, *lharx*, *lwarx*, *ldarx*, *stbcx*, *sthcx*, *stwcx*, or *stdcx* instruction refers to storage that is Write Through Required or Caching Inhibited.
- The access violates storage protection.
- A Data Address Breakpoint match occurs.
- Execution of an *eciwx* or *ecowx* instruction is disallowed because $EAR_E=0$.

If a *stbcx*, *sthcx*, *stwcx*, or *stdcx* would not perform its store in the absence of a Data Storage interrupt, and either (a) the specified effective address refers to storage that is Write Through Required or Caching Inhibited, or (b) a non-conditional *Store* to the specified effective address would cause a Data Storage interrupt, it is implementation-dependent whether a Data Storage interrupt occurs.

If the XER specifies a length of zero for an indexed *Move Assist* instruction, a Data Storage interrupt does not occur.

The following registers are set:

SRR0 Set to the effective address of the instruction that caused the interrupt.

SRR1

33:36 Set to 0.

42:47 Set to 0.

Others Loaded from the MSR.

MSR See Figure 44.

DSISR

32 Set to 0.

33 Set to 1 if $MSR_{DR}=1$ and the translation for an attempted access is not found in the Page Table; otherwise set to 0..

34:35 Set to 0.

36 Set to 1 if the access is not permitted by Figure 27 or 28, as appropriate; otherwise set to 0.

37 Set to 1 if the access is due to a *lq*, *stq*, *lbarx*, *lharx*, *lwarx*, *ldarx*, *stbcx*, *sthcx*, *stwcx*, or *stdcx* instruction that addresses storage that is Write Through Required or Caching Inhibited; otherwise set to 0.

38 Set to 1 for a *Store*, *dcbz*, or *ecowx* instruction; otherwise set to 0.

39:40 Set to 0.

41 Set to 1 if a Data Address Breakpoint match occurs; otherwise set to 0.

42 Set to 1 if the access is not permitted by virtual page class key protection; otherwise set to 0.

Programming Note

Storage protection violations for the Data Storage interrupt are reported in $DSISR_{36}$ and $DSISR_{42}$, whereas storage protection violations for the Instruction Storage interrupt are reported in $SRR1_{35}$ and $SRR1_{36}$.

43 Set to 1 if execution of an *eciwx* or *ecowx* instruction is attempted when $EAR_E=0$; otherwise set to 0.

44:63 Set to 0.

DAR

Set to the effective address of a storage element as described in the following list. The list should be read from the top down; the DAR is set as described by the first item that corresponds to an exception that is reported in the DSISR. For example, if a *Load Word* instruction causes a storage protection violation and a Data Address Breakpoint match (and both are reported in the DSISR), the DAR is set to the effective address of a byte in the first aligned doubleword for which access was attempted in the page that caused the exception.

- a Data Storage exception occurs for reasons other than a Data Address Breakpoint match or, for *eciwx* and *ecowx*, $EAR_E=0$
 - a byte in the block that caused the exception, for a *Cache Management* instruction
 - a byte in the first aligned quadword for which access was attempted in the page that caused

the exception, for a quadword *Load* or *Store* instruction (i.e., a *Load* or *Store* instruction for which the storage operand is a quadword; “first” refers to address order: see Section 6.7)

- a byte in the first aligned doubleword for which access was attempted in the page that caused the exception, for a non-quadword *Load* or *Store* instruction or an *eciwX* or *ecowX* instruction
- undefined, for a Data Address Breakpoint match, or if *eciwX* or *ecowX* is executed when $\text{EAR}_E=0$

For the cases in which the DAR is specified above to be set to a defined value, if the interrupt occurs in 32-bit mode the high-order 32 bits of the DAR are set to 0.

If multiple Data Storage exceptions occur for a given effective address, any one or more of the bits corresponding to these exceptions may be set to 1 in the DSISR.

Execution resumes at effective address 0x0000_0000_0000_0300.

6.5.4 Data Segment Interrupt

A Data Segment interrupt occurs when no higher priority exception exists and a data access cannot be performed because data address translation is enabled and the effective address of any byte of the storage location specified by a *Load*, *Store*, *icbi*, *dcbz*, *dcbst*, *dcbf[!]* *eciwX*, or *ecowX* instruction cannot be translated to a virtual address.

If a *stbcX*, *sthcX*, *stwcX*, or *stdcX* would not perform its store in the absence of a Data Segment interrupt and a non-conditional *Store* to the specified effective address would cause a Data Segment interrupt, it is implementation-dependent whether a Data Segment interrupt occurs.

If the XER specifies a length of zero for an indexed *Move Assist* instruction, a Data Segment interrupt does not occur.

The following registers are set:

SRR0	Set to the effective address of the instruction that caused the interrupt.
SRR1	
33:36	Set to 0.
42:47	Set to 0.
Others	Loaded from the MSR.
MSR	See Figure 44.
DSISR	Set to an undefined value.

DAR Set to the effective address of a storage element as described in the following list.

- a byte in the block that caused the exception, for a *Cache Management* instruction
- a byte in the first aligned quadword for which access was attempted in the segment that caused the exception, for a quadword *Load* or *Store* instruction (i.e., a *Load* or *Store* instruction for which the storage operand is a quadword; “first” refers to address order: see Section 6.7)
- a byte in the first aligned doubleword for which access was attempted in the segment that caused the exception, for a non-quadword *Load* or *Store* instruction or an *eciwX* or *ecowX* instruction

If the interrupt occurs in 32-bit mode the high-order 32 bits of the DAR are set to 0.

Execution resumes at effective address 0x0000_0000_0000_0380.

Programming Note

A Data Segment interrupt occurs if $\text{MSR}_{\text{DR}}=1$ and the translation of the effective address of any byte of the specified storage location is not found in the SLB (or in any implementation-specific address translation lookaside information).

6.5.5 Instruction Storage Interrupt

An Instruction Storage interrupt occurs when no higher priority exception exists, the value of the expression

$$(\text{MSR}_{\text{HV PR}} = 0\text{b}10) \mid (\neg\text{VPM}_0 \ \& \ \neg\text{MSR}_{\text{IR}}) \\ \mid (\neg\text{VPM}_1 \ \& \ \text{MSR}_{\text{IR}})$$

is 1, and the next instruction to be executed cannot be fetched for any of the following reasons.

- Instruction address translation is enabled and the virtual address cannot be translated to a real address.
- The fetch access violates storage protection.

The following registers are set:

SRR0	Set to the effective address of the instruction that the thread would have attempted to execute next if no interrupt conditions were present (if the interrupt occurs on attempting to fetch a branch target, SRR0 is set to the branch target address).
SRR1	
33	Set to 1 if $\text{MSR}_{\text{IR}}=1$ and the translation for an attempted access is not found in the Page Table; otherwise set to 0.
34	Set to 0.

- 35** Set to 1 if the access is to No-execute or Guarded storage; otherwise set to 0.
- 36** Set to 1 if the access is not permitted by Figure 27 or 28, as appropriate; otherwise set to 0.

Programming Note

Storage protection violations for the Instruction Storage interrupt are reported in SRR1₃₅ and SRR1₃₆, whereas storage protection violations for the Data Storage interrupt are reported in DSISR₃₆ and DSISR₄₂.

42:47 Set to 0.

Others Loaded from the MSR.

MSR See Figure 44.

If multiple Instruction Storage exceptions occur due to attempting to fetch a single instruction, any one or more of the bits corresponding to these exceptions may be set to 1 in SRR1.

Execution resumes at effective address 0x0000_0000_0000_0400.

6.5.6 Instruction Segment Interrupt

An Instruction Segment interrupt occurs when no higher priority exception exists and the next instruction to be executed cannot be fetched because instruction address translation is enabled and the effective address cannot be translated to a virtual address.

The following registers are set:

SRR0 Set to the effective address of the instruction that the thread would have attempted to execute next if no interrupt conditions were present (if the interrupt occurs on attempting to fetch a branch target, SRR0 is set to the branch target address).

SRR1

33:36 Set to 0.

42:47 Set to 0.

Others Loaded from the MSR.

MSR See Figure 44 on page 828.

Execution resumes at effective address 0x0000_0000_0000_0480.

Programming Note

An Instruction Segment interrupt occurs if MSR_{IR}=1 and the translation of the effective address of the next instruction to be executed is not found in the SLB (or in any implementation-specific address translation lookaside information).

6.5.7 External Interrupt

An External interrupt is classified as being either a Direct External interrupt or a Mediated External interrupt. Throughout this Book, usage of the phrase “External interrupt”, without further classification, refers to both a Direct External interrupt and a Mediated External interrupt.

6.5.7.1 Direct External Interrupt

A Direct External interrupt occurs when no higher priority exception exists, a Direct External exception exists, and the value of the expression

$$\text{MSR}_{EE} \mid (\neg(\text{LPES}_0) \ \& \ (\neg(\text{MSR}_{HV}) \mid \text{MSR}_{PR}))$$

is one. The occurrence of the interrupt does not cause the exception to cease to exist.

When LPES₀=0, the following registers are set:

HSRR0 Set to the effective address of the instruction that the thread would have attempted to execute next if no interrupt conditions were present.

HSRR1

33:36 Set to 0.

42:47 Set to 0.

Others Loaded from the MSR.

MSR See Figure 44 on page 828.

When LPES₀=1, the following registers are set:

SRR0 Set to the effective address of the instruction that the thread would have attempted to execute next if no interrupt conditions were present.

SRR1

33:36 Set to 0.

42:47 Set to 0.

Others Loaded from the MSR.

MSR See Figure 44 on page 828.

Execution resumes at effective address 0x0000_0000_0000_0500.

Programming Note

Because the value of MSR_{EE} is always 1 when the thread is in problem state, the simpler expression

$$\text{MSR}_{EE} \mid \neg(\text{LPES}_0 \mid \text{MSR}_{HV})$$

is equivalent to the expression given above.

Programming Note

The Direct External exception has the same meaning as the External exception in versions of the architecture prior to Version 2.05.

6.5.7.2 Mediated External Interrupt

A Mediated External interrupt occurs when no higher priority exception exists, a Mediated External exception exists (see the definition of $LPCR_{MER}$ in Section 2.2), and the value of the expression

$$MSR_{EE} \& (\neg(MSR_{HV}) \mid MSR_{PR})$$

is one. The occurrence of the interrupt does not cause the exception to cease to exist.

When $LPES_0=0$, the following registers are set:

HSRR0 Set to the effective address of the instruction that the thread would have attempted to execute next if no interrupt conditions were present.

HSRR1

33:36 Set to 0.

42 Set to 1.

43:47 Set to 0.

Others Loaded from the MSR.

MSR See Figure 44 on page 828.

When $LPES_0=1$, the following registers are set:

SRR0 Set to the effective address of the instruction that the thread would have attempted to execute next if no interrupt conditions were present.

SRR1

33:36 Set to 0.

42:47 Set to 0.

Others Loaded from the MSR.

MSR See Figure 44 on page 828.

Execution resumes at effective address $0x0000_0000_0000_0500$.

6.5.8 Alignment Interrupt

An Alignment interrupt occurs when no higher priority exception exists and a data access cannot be performed for any of the following reasons.

- The operand of a *Floating-Point Load*, a *Floating-Point Store*, a *Vector-Scalar Extension Load*, or a *Vector-Scalar Extension Store* is not word-aligned, or crosses a virtual page boundary.
- The operand of *lq*, *stq*, *lmw*, *stmw*, *lharx*, *lwarx*, *ldarx*, *sthcx.*, *stwcx.*, *stdcx.*, *eciwx*, *ecowx*, *ldp*, *ldpdx*, *stfdp*, or *stfdpx* is not aligned.
- The operand of a single-register *Load* or *Store* is not aligned and the thread is in Little-Endian mode.
- The instruction is *lq*, *stq*, *lmw*, *stmw*, *lswi*, *lswx*, *stswi*, or *stswx*, and the operand is in storage that is Write Through Required or Caching Inhibited, or the thread is in Little-Endian mode.
- The operand of a *Load* or *Store* crosses a segment boundary, or crosses a boundary between virtual

pages that have different storage control attributes.

- The operand of a *Load* or *Store* is not aligned and is in storage that is Write Through Required or Caching Inhibited.
- The operand of *ldp*, *ldpdx*, *stfdp*, *stfdpx*, *dcbz*, *lbarx*, *lharx*, *lwarx*, *ldarx*, *stbcx.*, *sthcx.*, *stwcx.*, or *stdcx.* is in storage that is Write Through Required or Caching Inhibited.

If a *stbcx.*, *sthcx.*, *stwcx.*, or *stdcx.* would not perform its store in the absence of an Alignment interrupt and the specified effective address refers to storage that is Write Through Required or Caching Inhibited, it is implementation-dependent whether an Alignment interrupt occurs.

If the XER specifies a length of zero for an indexed *Move Assist* instruction, an Alignment interrupt does not occur.

Setting the DSISR and DAR as described below is optional for implementations on which Alignment interrupts occur rarely, if ever, for cases that the Alignment interrupt handler emulates. For such implementations, if the DSISR and DAR are not set as described below they are set to undefined values.

The following registers are set:

SRR0 Set to the effective address of the instruction that caused the interrupt.

SRR1

33:36 Set to 0.

42:47 Set to 0.

Others Loaded from the MSR.

MSR See Figure 44.

DSISR

32:43 Set to 0.

44:45 Set to bits 30:31 of the instruction if DS-form. Set to 0b00 if D-, or X-form.

46 Set to 0.

47:48 Set to bits 29:30 of the instruction if X-form. Set to 0b00 if D- or DS-form.

49 Set to bit 25 of the instruction if X-form. Set to bit 5 of the instruction if D- or DS-form.

50:53 Set to bits 21:24 of the instruction if X-form. Set to bits 1:4 of the instruction if D- or DS-form.

54:58 Set to bits 6:10 of the instruction (RT/RS/FRT/FRS), except undefined for *dcbz*.

59:63 Set to bits 11:15 of the instruction (RA) for update form instructions; set to either bits 11:15 of the instruction or to any register number not in the range of registers to be loaded for a valid form *lmw*, a valid form *lswi*, or a valid form *lswx* for which neither RA nor RB is in the range of registers to be loaded; otherwise undefined.

DAR Set to the effective address computed by the instruction, except that if the interrupt occurs in 32-bit mode the high-order 32 bits of the DAR are set to 0.

For an X-form *Load* or *Store*, it is acceptable for the thread to set the DSISR to the same value that would have resulted if the corresponding D- or DS-form instruction had caused the interrupt. Similarly, for a D- or DS-form *Load* or *Store*, it is acceptable for the thread to set the DSISR to the value that would have resulted for the corresponding X-form instruction. For example, an unaligned *lwax* (that crosses a protection boundary) would normally, following the description above, cause the DSISR to be set to binary:

```
000000000000 00 0 01 0 0101 ttttt ?????
```

where “ttttt” denotes the RT field, and “?????” denotes an undefined 5-bit value. However, it is acceptable if it causes the DSISR to be set as for *lwa*, which is

```
000000000000 10 0 00 0 1101 ttttt ?????
```

If there is no corresponding alternative form instruction (e.g., for *lwaux*), the value described above is set in the DSISR.

The instruction pairs that may use the same DSISR value are.

lhz/lhxx	lhzu/lhux	lha/lhax	lhau/lhaux
lwz/lwxx	lwzu/lwux	lwa/lwax	
ld/ldx	ldu/ldux		
lsth/sthx	sthu/sthux	stw/stwx	stwu/stwux
std/stdx	stdu/stdux		
lfs/lfsx	lfsu/lfsux	lfd/lfdx	lfdu/lfdux
stfs/stfsx	stfsu/stfsux	stfd/stfdx	stfdu/stfdux

Execution resumes at effective address 0x0000_0000_0000_0600.

Programming Note

The architecture does not support the use of an unaligned effective address by *lharx*, *lwarx*, *ldarx*, *sthcx*, *stwcx*, *stdcx*, *eciwx*, and *ecowx*. If an Alignment interrupt occurs because one of these instructions specifies an unaligned effective address, the Alignment interrupt handler must not attempt to simulate the instruction, but instead should treat the instruction as a programming error.

6.5.9 Program Interrupt

A Program interrupt occurs when no higher priority exception exists and one of the following exceptions arises during execution of an instruction:

Floating-Point Enabled Exception

A Floating-Point Enabled Exception type Program interrupt is generated when the value of the expression

$$(MSR_{FE0} | MSR_{FE1}) \& FPSCR_{FEX}$$

is 1. $FPSCR_{FEX}$ is set to 1 by the execution of a floating-point instruction that causes an enabled exception, including the case of a *Move To FPSCR* instruction that causes an exception bit and the corresponding enable bit both to be 1.

Privileged Instruction

The following applies if the instruction is executed when $MSR_{PR} = 1$.

A Privileged Instruction type Program interrupt is generated when execution is attempted of a privileged instruction, or of an *mtspr* or *mfspr* instruction with an SPR field that contains a value having $spr_0=1$.

The following applies if the instruction is executed when $MSR_{HVPR} = 0b00$.

A Privileged Instruction type Program interrupt is generated when execution is attempted of an *mtspr* or *mfspr* instruction with an SPR field that designates an SPR that is accessible by the instruction only when the thread is in hypervisor state, or when execution of a hypervisor-privileged instruction is attempted.

Programming Note

These are the only cases in which a Privileged Instruction type Program interrupt can be generated when $MSR_{PR}=0$. They can be distinguished from other causes of Privileged Instruction type Program interrupts by examining $SRR1_{49}$ (the bit in which MSR_{PR} was saved by the interrupt).

Trap

A Trap type Program interrupt is generated when any of the conditions specified in a *Trap* instruction is met.

The following registers are set:

SRR0 For all Program interrupts except a Floating-Point Enabled Exception type Program interrupt, set to the effective address of the instruction that caused the corresponding exception.

For a Floating-Point Enabled Exception type Program interrupt, set as described in the following list.

- If $MSR_{FE0FE1} = 0b00$, $FPSCR_{FEX} = 1$, and an instruction is executed that changes MSR_{FE0FE1} to a nonzero value, set to the effective address of the instruc-

tion that the thread would have attempted to execute next if no interrupt conditions were present.

Programming Note

Recall that all instructions that can alter $MSR_{FE0\ FE1}$ are context synchronizing, and therefore are not initiated until all preceding instructions have reported all exceptions they will cause.

- If $MSR_{FE0\ FE} = 0b11$, set to the effective address of the instruction that caused the Floating-Point Enabled Exception.
- If $MSR_{FE0\ FE} = 0b01$ or $0b10$, set to the effective address of the first instruction that caused a Floating-Point Enabled Exception since the most recent time $FPSCR_{FEX}$ was changed from 1 to 0 or of some subsequent instruction.

Programming Note

If $SRR0$ is set to the effective address of a subsequent instruction, that instruction will not be beyond the first such instruction at which synchronization of floating-point instructions occurs. (Recall that such synchronization is caused by *Floating-Point Status and Control Register* instructions, as well as by execution synchronizing instructions and events.)

SRR1	
33:36	Set to 0.
42	Set to 0.
43	Set to 1 for a Floating-Point Enabled Exception type Program interrupt; otherwise set to 0.
44	Set to 0.
45	Set to 1 for a Privileged Instruction type Program interrupt; otherwise set to 0.
46	Set to 1 for a Trap type Program interrupt; otherwise set to 0.
47	Set to 0 if $SRR0$ contains the address of the instruction causing the exception and there is only one such instruction; otherwise set to 1.

Programming Note

$SRR1_{47}$ can be set to 1 only if the exception is a Floating-Point Enabled Exception and either $MSR_{FE0\ FE1} = 0b01$ or $0b10$ or $MSR_{FE0\ FE1}$ has just been changed from $0b00$ to a nonzero value. ($SRR1_{47}$ is always set to 1 in the last case.)

Others Loaded from the MSR.

Exactly one of bits 43, 45, and 46 is set to 1.

MSR See Figure 44 on page 828.

Execution resumes at effective address $0x0000_0000_0000_0700$.

Programming Note

In versions of the architecture that precede V. 2.05, the conditions that now cause a Hypervisor Emulation Assistance interrupt instead caused an “Illegal Instruction type Program interrupt”. This was a Program interrupt for which registers ($SRR0$, $SRR1$, and the MSR) were set as described above for the Privileged Instruction type Program interrupt, except that $SRR1_{44}$ was set to 1 and $SRR1_{45}$ was set to 0. Thus operating systems have code to handle these conditions, at the Program interrupt vector location. For this reason, if a Hypervisor Emulation Assistance interrupt occurs, when the thread is not in hypervisor state, for an instruction that the hypervisor does not emulate, the hypervisor should pass control to the operating system at the operating system’s Program interrupt vector location, with all registers ($SRR0$, $SRR1$, MSR, GPRs, etc.) set as if the instruction had caused a Privileged Instruction type Program interrupt, except with $SRR1_{44:45}$ set to $0b10$. (The Hypervisor Emulation Assistance interrupt was added to the architecture in V. 2.05, and the Illegal Instruction type Program interrupt was removed from the architecture in V. 2.06. In V. 2.05 the Hypervisor Emulation Assistance interrupt was optional: implementations that supported it generated it as described in V. 2.06, and never generated an Illegal Instruction type Program interrupt; implementations that did not support it generated an Illegal Instruction type Program interrupt as described above.)

6.5.10 Floating-Point Unavailable Interrupt

A Floating-Point Unavailable interrupt occurs when no higher priority exception exists, an attempt is made to execute a floating-point instruction (including floating-point loads, stores, and moves), and $MSR_{FP}=0$.

The following registers are set:

SRR0 Set to the effective address of the instruction that caused the interrupt.

SRR1
33:36 Set to 0.
42:47 Set to 0.

Others Loaded from the MSR.

MSR See Figure 44 on page 828.

Execution resumes at effective address 0x0000_0000_0000_0800.

6.5.11 Decrementer Interrupt

A Decrementer interrupt occurs when no higher priority exception exists, a Decrementer exception exists, and $MSR_{EE}=1$.

The following registers are set:

SRR0 Set to the effective address of the instruction that the thread would have attempted to execute next if no interrupt conditions were present.

SRR1
33:36 Set to 0.
42:47 Set to 0.
Others Loaded from the MSR.

MSR See Figure 44 on page 828.

Execution resumes at effective address 0x0000_0000_0000_0900.

6.5.12 Hypervisor Decrementer Interrupt

A Hypervisor Decrementer interrupt occurs when no higher priority exception exists, a Hypervisor Decrementer exception exists, and the value of the following expression is 1.

$$(MSR_{EE} \mid \neg(MSR_{HV}) \mid MSR_{PR}) \& HDICE$$

The following registers are set:

HSRR0 Set to the effective address of the instruction that the thread would have attempted to execute next if no interrupt conditions were present.

HSRR1
33:36 Set to 0.
42:47 Set to 0.
Others Loaded from the MSR.

MSR See Figure 44 on page 828.

Execution resumes at effective address 0x0000_0000_0000_0980.

Programming Note

Because the value of MSR_{EE} is always 1 when the thread is in problem state, the simpler expression

$$(MSR_{EE} \mid \neg(MSR_{HV})) \& HDICE$$

is equivalent to the expression given above.

6.5.13 System Call Interrupt

A System Call interrupt occurs when a *System Call* instruction is executed.

The following registers are set:

SRR0 Set to the effective address of the instruction following the System Call instruction.

SRR1
33:36 Set to 0.
42:47 Set to 0.
Others Loaded from the MSR.

MSR See Figure 44 on page 828.

Execution resumes at effective address 0x0000_0000_0000_0C00.

Programming Note

An attempt to execute an *sc* instruction with $LEV=1$ in problem state should be treated as a programming error.

6.5.14 Trace Interrupt [Category: Trace]

A Trace interrupt occurs when no higher priority exception exists and either $MSR_{SE}=1$ and any instruction except *rfd* or *hrfd*, is successfully completed, or $MSR_{BE}=1$ and a *Branch* instruction is completed. Successful completion means that the instruction caused no other interrupt. Thus a Trace interrupt never occurs for a *System Call* instruction, or for a *Trap* instruction that traps. The instruction that causes a Trace interrupt is called the “traced instruction”.

When a Trace interrupt occurs, the following registers are set:

SRR0 Set to the effective address of the instruction that the thread would have attempted to execute next if no interrupt conditions were present.

SRR1
33:36 and 42:47 Set to an implementation-dependent value.
Others Loaded from the MSR.

MSR See Figure 44 on page 828.

Execution resumes at effective address 0x0000_0000_0000_0D00.

Extensions to the Trace facility are described in Appendix C.

Programming Note

The following instructions are not traced.

- *rfid*
- *hrfid*
- *sc*, and *Trap* instructions that trap
- other instructions that cause interrupts (other than Trace interrupts)
- the first instructions of any interrupt handler
- instructions that are emulated by software

In general, interrupt handlers can achieve the effect of tracing these instructions.

6.5.15 Hypervisor Data Storage Interrupt

A Hypervisor Data Storage interrupt occurs when the thread is not in hypervisor state, no higher priority exception exists, the value of the expression

$$(VPM_0 \& \neg MSR_{DR}) \mid (VPM_1 \& MSR_{DR})$$

is 1, and a data access cannot be performed for any of the following reasons.

- Data address translation is enabled ($MSR_{DR}=1$) and the virtual address of any byte of the storage location specified by a *Load*, *Store*, *icbi*, *dcbz*, *dcbst*, *dcbf[]*, *eciwx*, or *ecowx* instruction cannot be translated to a real address.
- Data address translation is disabled ($MSR_{DR}=0$), $LPES_1=1$, and the virtual address of any byte of the storage location specified by a *Load*, *Store*, *icbi*, *dcbz*, *dcbst*, *dcbf[]*, *eciwx*, or *ecowx* instruction cannot be translated to a real address by means of the virtual real addressing mechanism.
- The effective address specified by a *lq*, *stq*, *lbarx*, *lharx*, *lwarx*, *ldarx*, *stbcx.*, *sthcx.*, *stwcx.*, or *stdcx.* instruction refers to storage that is Write Through Required or Caching Inhibited.
- The access violates storage protection.
- A Data Address Breakpoint match occurs.
- Execution of an *eciwx* or *ecowx* instruction is disallowed because $EAR_E=0$.

If a *stbcx.*, *sthcx.*, *stwcx.*, or *stdcx.* would not perform its store in the absence of a Hypervisor Data Storage interrupt, and either (a) the specified effective address refers to storage that is Write Through Required or Caching Inhibited, or (b) a non-conditional *Store* to the specified effective address would cause a Hypervisor Data Storage interrupt, it is implementation-dependent whether a Hypervisor Data Storage interrupt occurs.

If the XER specifies a length of zero for an indexed *Move Assist* instruction, a Hypervisor Data Storage interrupt does not occur.

The following registers are set:

HSRR0 Set to the effective address of the instruction that caused the interrupt.

HSRR1

33:36 Set to 0.

42:47 Set to 0.

Others Loaded from the MSR.

MSR See Figure 44.

HDSISR

32 Set to 0.

33 Set to 1 if the value of the expression $(MSR_{DR}) \mid ((\neg MSR_{DR} \& VPM_0) \& LPES_1)$

is 1 and the translation for an attempted access is not found in the Page Table; otherwise set to 0.

34:35 Set to 0.

36 Set to 1 if the access is not permitted by Figure 27 or 28, as appropriate; otherwise set to 0.

37 Set to 1 if the access is due to a *lq*, *stq*, *lbarx*, *lharx*, *lwarx*, *ldarx*, *stbcx.*, *sthcx.*, *stwcx.*, or *stdcx.* instruction that addresses storage that is Write Through Required or Caching Inhibited; otherwise set to 0.

38 Set to 1 for a *Store*, *dcbz*, or *ecowx* instruction; otherwise set to 0.

39:40 Set to 0.

41 Set to 1 if a Data Address Breakpoint match occurs; otherwise set to 0.

42 Set to 1 if the access is not permitted by virtual page class key protection; otherwise set to 0.

Programming Note

Storage protection violations for the Hypervisor Data Storage interrupt are reported in HDSISR₃₆ and HDSISR₄₂, whereas storage protection violations for the Hypervisor Instruction Storage interrupt are reported in HSRR₁₃₅ and HSRR₁₃₆.

43 Set to 1 if execution of an *eciwx* or *ecowx* instruction is attempted when $EAR_E=0$; otherwise set to 0.

44:63 Set to 0.

HDAR

Set to the effective address of a storage element as described in the following list. The list should be read from the top down; the HDAR is set as described by the first item that corresponds to an exception that is reported in the HDSISR. For example, if a *Load Word* instruction causes a storage protection violation and a Data Address Breakpoint match (and both are reported in

the HDSISR), the HDAR is set to the effective address of a byte in the first aligned doubleword for which access was attempted in the page that caused the exception.

- a Hypervisor Data Storage exception occurs for reasons other than a Data Address Breakpoint match or, for **eciwX** and **ecowX**, $EAR_E=0$
 - a byte in the block that caused the exception, for a *Cache Management* instruction
 - a byte in the first aligned quadword for which access was attempted in the page that caused the exception, for a quadword *Load* or *Store* instruction (i.e., a *Load* or *Store* instruction for which the storage operand is a quadword; “first” refers to address order: see Section 6.7)
 - a byte in the first aligned doubleword for which access was attempted in the page that caused the exception, for a non-quadword *Load* or *Store* instruction or an **eciwX** or **ecowX** instruction
- undefined, for a Data Address Breakpoint match, or if **eciwX** or **ecowX** is executed when $EAR_E=0$

For the cases in which the HDAR is specified above to be set to a defined value, if the interrupt occurs in 32-bit mode the high-order 32 bits of the HDAR are set to 0.

If multiple Hypervisor Data Storage exceptions occur for a given effective address, any one or more of the bits corresponding to these exceptions may be set to 1 in the HDSISR.

Execution resumes at effective address 0x0000_0000_0000_0E00.

6.5.16 Hypervisor Instruction Storage Interrupt

A Hypervisor Instruction Storage interrupt occurs when the thread is not in hypervisor state, no higher priority exception exists, the value of the expression

$$(VPM_0 \& \neg MSR_{IR}) \mid (VPM_1 \& MSR_{IR})$$

is 1, and the next instruction to be executed cannot be fetched for any of the following reasons.

- Instruction address translation is enabled ($MSR_{IR}=1$) and the virtual address cannot be translated to a real address.
- Instruction address translation is disabled ($MSR_{IR}=0$), $LPES_1=1$, and the virtual address

cannot be translated to a real address by means of the virtual real addressing mechanism.

- The fetch access violates storage protection.

The following registers are set:

HSRR0 Set to the effective address of the instruction that the thread would have attempted to execute next if no interrupt conditions were present (if the interrupt occurs on attempting to fetch a branch target, HSRR0 is set to the branch target address).

HSRR1

- 33** Set to 1 if the value of the expression $(MSR_{IR}) \mid ((\neg MSR_{IR} \& VPM_0) \& LPES_1)$ is 1 and the translation for an attempted access is not found in the Page Table; otherwise set to 0.
- 34** Set to 0.
- 35** Set to 1 if the access is to No-execute or Guarded storage; otherwise set to 0.
- 36** Set to 1 if the access is not permitted by Figure 27 or 28, as appropriate; otherwise set to 0.

Programming Note

Storage protection violations for the Hypervisor Instruction Storage interrupt are reported in HSRR1₃₅ and HSRR1₃₆, whereas storage protection violations for the Hypervisor Data Storage interrupt are reported in HDSISR₃₆ and HDSISR₄₂.

- 42:46** Set to 0.
- 47** Set to 0.
- Others** Loaded from the MSR.

MSR See Figure 44.

If multiple Hypervisor Instruction Storage exceptions occur due to attempting to fetch a single instruction, any one or more of the bits corresponding to these exceptions may be set to 1 in HSRR1.

Execution resumes at effective address 0x0000_0000_0000_0E10.

6.5.17 Hypervisor Emulation Assistance Interrupt

A Hypervisor Emulation Assistance interrupt is generated when execution is attempted of an illegal instruction, or of a reserved instruction or an instruction that is not provided by the implementation. It is also generated under the following conditions.

- an *mtspr* or *mfspir* instruction is executed when $MSR_{PR}=1$ if the instruction specifies an SPR with $spr_0=0$ that is not provided by the implementation
- an *mtspr* or *mfspir* instruction is executed when $MSR_{PR}=0$ if the instruction specifies SPR 0
- an *mfspir* instruction is executed when $MSR_{PR}=0$ if the instruction specifies SPR 4, 5, or 6

A Hypervisor Emulation Assistance interrupt may be generated when execution is attempted of any of the following kinds of instruction.

- an instruction that is in invalid form
- an *lswx* instruction for which RA or RB is in the range of registers to be loaded

The following registers are set:

HSRR0 Set to the effective address of the instruction that caused the interrupt.

HSRR1

33:36 Set to 0.

42:47 Set to 0.

Others Loaded from the MSR.

MSR See Figure 44 on page 828.

HEIR Set to a copy of the instruction that caused the interrupt

Execution resumes at effective address 0x0000_0000_0000_0E40.

Programming Note

If a Hypervisor Emulation Assistance interrupt occurs, when the thread is not in hypervisor state, for an instruction that the hypervisor does not emulate, the hypervisor should pass control to the operating system as if the instruction had caused an "Illegal Instruction type Program interrupt", as described in a Programming Note near the end of Section 6.5.9, "Program Interrupt" on page 837.

6.5.18 Hypervisor Maintenance Interrupt

A Hypervisor Maintenance interrupt occurs when no higher priority exception exists, a Hypervisor Maintenance exception exists (a bit in the HMER is set to one), the exception is enabled in the HMEER, and the value of the following expression is 1.

$$(MSR_{EE} \mid \neg(MSR_{HV}) \mid MSR_{PR})$$

The following registers are set:

HSRR0 Set to the effective address of the instruction that the thread would have attempted to execute next if no interrupt conditions were present.

HSRR1

33:36 Set to 0.

42:47 Set to 0.

Others Loaded from the MSR.

MSR See Figure 44 on page 828.

HMER See Section 6.2.8 on page 823.

The exception bits in the HMER are sticky; that is, once set to 1 they remain set to 1 until they are set to 0 by an *mtmmer* instruction.

Execution resumes at effective address 0x0000_0000_0000_0E60.

Programming Note

Because the value of MSR_{EE} is always 1 when the thread is in problem state, the simpler expression

$$(MSR_{EE} \mid \neg(MSR_{HV}))$$

is equivalent to the expression given above.

Programming Note

If an implementation uses the HMER to record that a readable resource, such as the Time Base, has been corrupted, then, because the HMI is disabled in the hypervisor state, it is necessary for the hypervisor to check HMER after reading that resource to be sure an error has not occurred.

6.5.19 Performance Monitor Interrupt [Category: Server.Performance Monitor]

The Performance Monitor interrupt is part of the Performance Monitor facility; see Appendix C. If the Performance Monitor facility is not implemented or does not use this interrupt, the corresponding interrupt vector (see Figure 45 on page 829) is treated as reserved.

6.5.20 Vector Unavailable Interrupt [Category: Vector]

A Vector Unavailable interrupt occurs when no higher priority exception exists, an attempt is made to execute a Vector instruction (including Vector loads, stores, and moves), and $MSR_{VEC}=0$.

The following registers are set:

SRR0 Set to the effective address of the instruction that caused the interrupt.

SRR1

33:36 Set to 0.

42:47 Set to 0.

Others Loaded from the MSR.

MSR See Figure 44 on page 828.

Execution resumes at effective address
0x0000_0000_0000_0F20.

6.5.21 VSX Unavailable Interrupt [Category: VSX]

A VSX Unavailable interrupt occurs when no higher priority exception exists, an attempt is made to execute a VSX instruction (including VSX loads, stores, and moves), and $MSR_{VSX}=0$.

The following registers are set:

SRR0 Set to the effective address of the instruction that caused the interrupt.

SRR1

33:36 Set to 0.

42:47 Set to 0.

Others Loaded from the MSR.

MSR See Figure 44 on page 828.

Execution resumes at effective address
0x0000_0000_0000_0F40.

6.6 Partially Executed Instructions

If a Data Storage, Data Segment, Alignment, system-caused, or imprecise exception occurs while a *Load* or *Store* instruction is executing, the instruction may be aborted. In such cases the instruction is not completed, but may have been partially executed in the following respects.

- Some of the bytes of the storage operand may have been accessed, except that if access to a given byte of the storage operand would violate storage protection, that byte is neither copied to a register by a *Load* instruction nor modified by a *Store* instruction. Also, the rules for storage accesses given in Section 5.8.1, “Guarded Storage” and in Section 2.1 of Book II are obeyed.
- Some registers may have been altered as described in the Book II section cited above.
- Reference and Change bits may have been updated as described in Section 5.7.8.
- For a *stbcx.*, *sthcx.*, *stwcx.*, or *stdcx.* instruction that is executed in-order, CR0 may have been set to an undefined value and the reservation may have been cleared.

The architecture does not support continuation of an aborted instruction but intends that the aborted instruction be re-executed if appropriate.

Programming Note

An exception may result in the partial execution of a *Load* or *Store* instruction. For example, if the Page Table Entry that translates the address of the storage operand is altered, by a program running on another thread, such that the new contents of the Page Table Entry preclude performing the access, the alteration could cause the *Load* or *Store* instruction to be aborted after having been partially executed.

As stated in the Book II section cited above, if an instruction is partially executed the contents of registers are preserved to the extent that the instruction can be re-executed correctly. The consequent preservation is described in the following list. For any given instruction, zero, one, or two items in the list apply.

- For a fixed-point *Load* instruction that is not a multiple or string form, or for an *eciwX* instruction, if $RT=RA$ or $RT=RB$ then the contents of register RT are not altered.
- For an *lq* instruction, if $RT+1 = RA$ then the contents of register $RT+1$ are not altered.
- For an update form *Load* or *Store* instruction, the contents of register RA are not altered.

6.7 Exception Ordering

Since multiple exceptions can exist at the same time and the architecture does not provide for reporting more than one interrupt at a time, the generation of more than one interrupt is prohibited. Some exceptions, such as the Mediated External exception, persist and can be deferred. However, other exceptions would be lost if they were not recognized and handled when they occur. For example, if an External interrupt was generated when a Data Storage exception existed, the Data Storage exception would be lost. If the Data Storage exception was caused by a *Store Multiple* instruction for which the storage operand crosses a virtual page boundary and the exception was a result of attempting to access the second virtual page, the store could have modified locations in the first virtual page even though it appeared that the *Store Multiple* instruction was never executed.

For the above reasons, all exceptions are prioritized with respect to other exceptions that may exist at the same instant to prevent the loss of any exception that is not persistent. Some exceptions cannot exist at the same instant as some others.

Data Storage, Hypervisor Data Storage, and Alignment exceptions occur as if the storage operand were accessed one byte at a time in order of increasing effective address (with the obvious caveat if the operand includes both the maximum effective address and effective address 0).

6.7.1 Unordered Exceptions

The exceptions listed here are unordered, meaning that they may occur at any time regardless of the state of the interrupt processing mechanism. These exceptions are recognized and processed when presented.

1. System Reset
2. Machine Check

6.7.2 Ordered Exceptions

The exceptions listed here are ordered with respect to the state of the interrupt processing mechanism. In the following list, the hypervisor forms of the Data Storage and Instruction Storage exceptions can be substituted for the non-hypervisor forms since the hypervisor forms cannot be caused by the same instruction and have the same ordering.

System-Caused or Imprecise

1. Program
 - Imprecise Mode Floating-Point Enabled Exception
2. Hypervisor Maintenance
3. External and [Hypervisor] Decrementer

Instruction-Caused and Precise

1. Instruction Segment
2. [Hypervisor] Instruction Storage
- 3.a Hypervisor Emulation Assistance
- 3.b Program
 - Privileged Instruction
4. Function-Dependent
 - 4.a Fixed-Point and Branch
 - 1a Program
 - Trap
 - 1b System Call
 - 1c [Hypervisor] Data Storage, [Hypervisor] Data Segment, or Alignment
 - 2 Trace
 - 4.b Floating-Point
 - 1 FP Unavailable
 - 2a Program
 - Precise Mode Floating-Pt Enabled Excep'n
 - 2b [Hypervisor] Data Storage, [Hypervisor] Data Segment, or Alignment
 - 3 Trace
 - 4.c Vector
 - 1 Vector Unavailable
 - 2a [Hypervisor] Data Storage, [Hypervisor] Data Segment, or Alignment
 - 3 Trace

For implementations that execute multiple instructions in parallel using pipeline or superscalar techniques, or combinations of these, it can be difficult to understand the ordering of exceptions. To understand this ordering it is useful to consider a model in which each instruction is fetched, then decoded, then executed, all before the next instruction is fetched. In this model, the exceptions a single instruction would generate are in the order shown in the list of instruction-caused exceptions. Exceptions with different numbers have different ordering. Exceptions with the same numbering but different lettering are mutually exclusive and cannot be caused by the same instruction. The External, Decrementer, and Hypervisor Decrementer interrupts have equal ordering. Similarly, where Data Storage, Data Segment, and Alignment exceptions are listed in the same item they have equal ordering.

Even on threads that are capable of executing several instructions simultaneously, or out of order, instruction-caused interrupts (precise and imprecise) occur in program order.

6.8 Interrupt Priorities

This section describes the relationship of non-maskable, maskable, precise, and imprecise interrupts. In the following descriptions, the interrupt mechanism waiting for all possible exceptions to be reported includes only exceptions caused by previously initiated instructions (e.g., it does not include waiting for the Decrementer to step through zero). The exceptions

are listed in order of highest to lowest priority. The phrase "corresponding interrupt" means the interrupt having the same name as the exception unless the thread is in power-saving mode, in which case the phrase means the System Reset interrupt.

Unless otherwise stated or obvious from context, it is assumed below that one of the following conditions is satisfied.

- The thread is not in power-saving mode and the interrupt, unless it is the Machine Check interrupt, is not disabled. (For the Machine Check interrupt no assumption is made regarding enablement.)
- The thread is in power-saving mode and the exception is enabled to cause exit from the mode.

In the following list, the hypervisor forms of the Data Storage and Instruction Storage exceptions can be substituted for the non-hypervisor forms since the hypervisor forms cannot be caused by the same instruction and have the same priority.

1. System Reset

System Reset exception has the highest priority of all exceptions. If this exception exists, the interrupt mechanism ignores all other exceptions and generates a System Reset interrupt.

Once the System Reset interrupt is generated, no nonmaskable interrupts are generated due to exceptions caused by instructions issued prior to the generation of this interrupt.

2. Machine Check

Machine Check exception is the second highest priority exception. If this exception exists and a System Reset exception does not exist, the interrupt mechanism ignores all other exceptions and generates a Machine Check interrupt.

Once the Machine Check interrupt is generated, no nonmaskable interrupts are generated due to exceptions caused by instructions issued prior to the generation of this interrupt.

3. Instruction-Dependent

This exception is the third highest priority exception. When this exception is created, the interrupt mechanism waits for all possible Imprecise exceptions to be reported. It then generates the appropriate ordered interrupt if no higher priority exception exists when the interrupt is to be generated. Within this category a particular instruction may present more than a single exception. When this occurs, those exceptions are ordered in priority as indicated in the following lists. Where [Hypervisor] Data Storage, Data Segment, and Alignment exceptions are listed in the same item they have equal priority (i.e., the hardware may generate any

one of the three interrupts for which an exception exists).

A. Fixed-Point Loads and Stores

- a. These exceptions are mutually exclusive and have the same priority:
 - Hypervisor Emulation Assistance
 - Program - Privileged Instruction
- b. [Hypervisor] Data Storage, [Hypervisor] Data Segment, or Alignment
- c. Trace

B. Floating-Point Loads and Stores

- a. Hypervisor Emulation Assistance
- b. Floating-Point Unavailable
- c. [Hypervisor] Data Storage, [Hypervisor] Data Segment, or Alignment
- d. Trace

C. Vector Loads and Stores

- a. Hypervisor Emulation Assistance
- b. Vector Unavailable
- c. [Hypervisor] Data Storage, [Hypervisor] Data Segment, or Alignment
- d. Trace

D. Other Floating-Point Instructions

- a. Floating-Point Unavailable
- b. Program - Precise Mode Floating-Point Enabled Exception
- c. Trace

E. Other Vector Instructions

- a. Vector Unavailable
- b. Trace

F. *rfid*, *hrfid* and *mtmsr[d]*

- a. Program - Privileged Instruction
- b. Program - Floating-Point Enabled Exception
- c. Trace, for *mtmsr[d]* only

G. Other Instructions

- a. These exceptions are mutually exclusive and have the same priority:
 - Program - Trap
 - System Call
 - Program - Privileged Instruction
 - Hypervisor Emulation Assistance
- b. Trace

H. [Hypervisor] Instruction Storage and Instruction Segment

These exceptions have the lowest priority in this category. They are recognized only when all instructions prior to the instruction causing one of these exceptions appear to have completed and that instruction is the next instruction to be executed. The two exceptions are mutually exclusive.

The priority of these exceptions is specified for completeness and to ensure that they are not given more favorable treatment. It is acceptable for an implementation to treat these

exceptions as though they had a lower priority.

4. Program - Imprecise Mode Floating-Point Enabled Exception

This exception is the fourth highest priority exception. When this exception is created, the interrupt mechanism waits for all other possible exceptions to be reported. It then generates this interrupt if no higher priority exception exists when the interrupt is to be generated.

5. Hypervisor Maintenance

This exception is the fifth highest priority exception. When this exception is created, the interrupt mechanism waits for all other possible exceptions to be reported. It then generates this interrupt if no higher priority exception exists when the interrupt is to be generated.

If a Hypervisor Maintenance exception exists and each attempt to execute an instruction when the Hypervisor Maintenance interrupt is enabled causes an exception (see the Programming Note below), the Hypervisor Maintenance interrupt is not delayed indefinitely.

6. Direct External, Mediated External, and [Hypervisor] Decrementer

These exceptions are the lowest priority exceptions. All have equal priority (i.e., the hardware may generate any one of the corresponding interrupts for which an exception exists). When one of these exceptions is created, the interrupt processing mechanism waits for all other possible exceptions to be reported. It then generates the corresponding interrupt if no higher priority exception exists when the interrupt is to be generated.

If a Hypervisor Decrementer exception exists and each attempt to execute an instruction when the Hypervisor Decrementer interrupt is enabled causes an exception (see the Programming Note below), the Hypervisor Decrementer interrupt is not delayed indefinitely.

If $LPES_0=1$ and a Direct External exception exists and each attempt to execute an instruction when this interrupt is enabled causes an exception (see the Programming Note below), the Direct External interrupt is not delayed indefinitely.

Programming Note

An incorrect or malicious operating system could corrupt the first instruction in the interrupt vector location for an instruction-caused interrupt such that the attempt to execute the instruction causes the same exception that caused the interrupt (a looping interrupt; e.g., *Trap* instruction and Program interrupt). Similarly, the first instruction of the interrupt vector for one instruction-caused interrupt could cause a different instruction-caused interrupt, and the first instruction of the interrupt vector for the second instruction-caused interrupt could cause the first instruction-caused interrupt (e.g., Program interrupt and Floating-Point Unavailable interrupt). Similarly, if the Real Mode Area is virtualized and there is no PTE for the page containing the interrupt vectors, every attempt to execute the first instruction of the OS's Instruction Storage interrupt handler would cause a Hypervisor Instruction Storage interrupt; if the Hypervisor Instruction Storage interrupt handler returns to the OS's Instruction Storage interrupt handler without the relevant PTE having been created, another Hypervisor Instruction Storage interrupt would occur immediately. The looping caused by these and similar cases is terminated by the occurrence of a System Reset or Hypervisor Decrementer interrupt.

Chapter 7. Timer Facilities

7.1 Overview	849	7.4 Hypervisor Decrementer	851
7.2 Time Base (TB)	849	7.5 Processor Utilization of Resources Register (PURR)	852
7.2.1 Writing the Time Base	850	7.6 Scaled Processor Utilization of Resources Register (SPURR)	853
7.3 Decrementer	850		
7.3.1 Writing and Reading the Decrementer	851		

7.1 Overview

The Time Base, Decrementer, Hypervisor Decrementer, Processor Utilization of Resources, and Scaled Processor Utilization of Resources registers provide timing functions for the system. The remainder of this section describes these registers and related facilities.

7.2 Time Base (TB)

The Time Base (TB) is a 64-bit register (see Figure 46) containing a 64-bit unsigned integer that is incremented periodically.

Field	Description
TBU40	Upper 40 bits of Time Base
TBU	Upper 32 bits of Time Base
TBL	Lower 32 bits of Time Base

Figure 46. Time Base

The Time Base is a hypervisor resource; see Chapter 2.

The SPRs TBU40, TBU, and TBL provide access to the fields of the Time Base shown in Figure 46. When a *mtspr* instruction is executed specifying one of these SPRs, the associated field of the Time Base is altered and the remaining bits of the Time Base are not affected.

See Chapter 5 of Book II for information about the update frequency of the Time Base.

The Time Base is implemented such that:

1. Loading a GPR from the Time Base has no effect on the accuracy of the Time Base.
2. Copying the contents of a GPR to the Time Base replaces the contents of the Time Base with the contents of the GPR.

The Power ISA does not specify a relationship between the frequency at which the Time Base is updated and other frequencies, such as the CPU clock or bus clock in a Power ISA system. The Time Base update frequency is not required to be constant. What *is* required, so that system software can keep time of day and operate interval timers, is one of the following.

- The system provides an (implementation-dependent) interrupt to software whenever the update frequency of the Time Base changes, and a means to determine what the current update frequency is.
- The update frequency of the Time Base is under the control of the system software.

Implementations must provide a means for either preventing the Time Base from incrementing or preventing it from being read in problem state ($MSR_{PR}=1$). If the means is under software control, it must be privileged and, in implementations of the Server environment, must be accessible only in hypervisor state ($MSR_{HV,PR}=0b10$). There must be a method for getting all Time Bases in the system to start incrementing with values that are identical or almost identical.

Programming Note

If software initializes the Time Base on power-on to some reasonable value and the update frequency of the Time Base is constant, the Time Base can be used as a source of values that increase at a constant rate, such as for time stamps in trace entries.

Even if the update frequency is not constant, values read from the Time Base are monotonically increasing (except when the Time Base wraps from $2^{64}-1$ to 0). If a trace entry is recorded each time the update frequency changes, the sequence of Time Base values can be post-processed to become actual time values.

Successive readings of the Time Base may return identical values.

If Time Base bits 60:63 are used as part of a random number generator, software must account for the fact that these bits are set to 0x0 only when bit 59 changes state regardless of whether or not they incremented to 0xF since they were previously set to 0x0.

See the description of the Time Base in Chapter of Book II for ways to compute time of day in POSIX format from the Time Base.

7.2.1 Writing the Time Base

Writing the Time Base is privileged, and can be done only in hypervisor state. Reading the Time Base is not privileged; it is discussed in Chapter 5 of Book II.

It is not possible to write the entire 64-bit Time Base using a single instruction. The *mttbl* and *mttbu* extended mnemonics write the lower and upper halves of the Time Base (TBL and TBU), respectively, preserving the other half. These are extended mnemonics for the *mtspr* instruction; see Appendix A, “Assembler Extended Mnemonics” on page 867.

The Time Base can be written by a sequence such as:

```
lwz    Rx,upper # load 64-bit value for
lwz    Ry,lower # TB into Rx and Ry
li     Rz,0
mttbl  Rz      # set TBL to 0
mttbu  Rx      # set TBU
mttbl  Ry      # set TBL
```

Provided that no interrupts occur while the last three instructions are being executed, loading 0 into TBL prevents the possibility of a carry from TBL to TBU while the Time Base is being initialized.

The preferred method of changing the Time Base utilizes the TBU40 facility. The following code sequence demonstrates the process. Assume the upper 40 bits of

Rx contain the desired value upper 40 bits of the Time Base.

```
mftb  Ry      # Read 64-bit Time Base value
clrldi Ry,Ry,40# lower 24 bits of old TB
mttbu40Rx # write upper 40 bits of TB
mftb  Rz      # read TB value again
clrldi Rz,Rz,40# lower 24 bits of new TB
cmpld  Rz,Ry  # compare new and old lwr 24
bge    done   # no carry out of low 24 bits
addis  Rx,Rx,0x0100#increment upper 40 bits
mttbu40 Rx    # update to adjust for carry
```

Programming Note

The instructions for writing the Time Base are mode-independent. Thus code written to set the Time Base will work correctly in either 64-bit or 32-bit mode.

7.3 Decrementer

The Decrementer (DEC) is a 32-bit decrementing counter that provides a mechanism for causing a Decrementer interrupt after a programmable delay. The contents of the Decrementer are treated as a signed integer.

Figure 47. Decrementer

The Decrementer counts down.

Decrementer bits 32:59 count down until their value becomes 0x000_0000, at the next decrement their value becomes 0xFFFF_FFFF. Decrementer bits 60:63 may decrement at a variable rate. When the value of bit 59 changes, bits 60:63 are set to 0xF; if bits 60:63 decrement to 0x0 before the value of bit 59 changes, they remain at 0x0 until the value of bit 59 changes.

The Decrementer is driven at the same frequency as the Time Base. The period of the Decrementer will depend on the driving frequency, but if the same values are used as given earlier for the Time Base (see Section 5.2 of Book II), and if the Time Base update frequency is constant, the period would be

$$T_{\text{DEC}} = \frac{2^{32} \times 32}{1 \text{ GHz}} = 137 \text{ seconds.}$$

When the contents of DEC₃₂ change from 0 to 1, a Decrementer exception will come into existence within a reasonable period of time. When the contents of DEC₃₂ change from 1 to 0, the existing Decrementer exception, if any, will cease to exist within a reasonable period of time, but not later than the completion of the next context synchronizing instruction or event.

The preceding paragraph applies regardless of whether the change in the contents of DEC_{32} is the result of decrementation of the Decrementer by the hardware or of modification of the Decrementer caused by execution of an *mtspr* instruction.

The operation of the Decrementer has the following additional properties.

1. Loading a GPR from the Decrementer has no effect on the accuracy of the Time Base.
2. Copying the contents of a GPR to the Decrementer replaces the contents of the Decrementer with the contents of the GPR.

Programming Note

In systems that change the Time Base update frequency for purposes such as power management, the Decrementer input frequency will also change. Software must be aware of this in order to set interval timers.

If Decrementer bits 60:63 are used as part of a random number generator, software must account for the fact that these bits are set to 0xF only when bit 59 changes state regardless of whether or not they decremented to 0x0 since they were previously set to 0xF.

7.3.1 Writing and Reading the Decrementer

The contents of the Decrementer can be read or written using the *mtspr* and *mtspr* instructions, both of which are privileged when they refer to the Decrementer. Using an extended mnemonic (see Appendix A, “Assembler Extended Mnemonics” on page 867), the Decrementer can be written from GPR Rx using:

```
mtdec Rx
```

The Decrementer can be read into GPR Rx using:

```
mfdec Rx
```

Copying the Decrementer to a GPR has no effect on the Decrementer contents or on the interrupt mechanism.

7.4 Hypervisor Decrementer

The Hypervisor Decrementer (HDEC) is a 32-bit decrementing counter that provides a mechanism for causing a Hypervisor Decrementer interrupt after a program-

ble delay. The contents of the Hypervisor Decrementer are treated as a signed integer.

Figure 48. Hypervisor Decrementer

The Hypervisor Decrementer is a hypervisor resource; see Chapter 2.

Hypervisor Decrementer bits 32:59 count down until their value becomes 0x000_0000, at the next decrement their value becomes 0xFFF_FFFF. Bits 60:63 may decrement at a variable rate. When the value of bit 59 changes, bits 60:63 are set to 0xF; if bits 60:63 decrement to 0x0 before the value of bit 59 changes, they remain at 0x0 until the value of bit 59 changes.

The Hypervisor Decrementer is driven at the same frequency as the Time Base. The period of the Hypervisor Decrementer will depend on the driving frequency, but if the same values are used as given above for the Time Base (see Section 7.2), and if the Time Base update frequency is constant, the period would be

$$T_{\text{DEC}} = \frac{2^{32} \times 32}{1 \text{ GHz}} = 137 \text{ seconds.}$$

When the contents of HDEC_{32} change from 0 to 1 and the thread is not in a power-saving mode, a Hypervisor Decrementer exception will come into existence within a reasonable period of time. When a Hypervisor Decrementer interrupt occurs, the existing Hypervisor Decrementer exception will cease to exist within a reasonable period of time, but not later than the completion of the next context synchronizing instruction or event. Even if multiple HDEC_{32} transitions from 0 to 1 occur before a Hypervisor Decrementer interrupt occurs, at most one Hypervisor Decrementer exception exists.

The preceding paragraph applies regardless of whether the change in the contents of HDEC_{32} is the result of decrementation of the Hypervisor Decrementer by the hardware or of modification of the Hypervisor Decrementer caused by execution of an *mtspr* instruction.

The operation of the Hypervisor Decrementer has the following additional properties.

1. Loading a GPR from the Hypervisor Decrementer has no effect on the accuracy of the Hypervisor Decrementer.
2. Copying the contents of a GPR to the Hypervisor Decrementer replaces the contents of the Hypervisor Decrementer with the contents of the GPR.

Programming Note

In systems that change the Time Base update frequency for purposes such as power management, the Hypervisor Decrementer update frequency will also change. Software must be aware of this in order to set interval timers.

If Hypervisor Decrementer bits 60:63 are used as part of a random number generator, software must account for the fact that these bits are set to 0xF only when bit 59 changes state regardless of whether or not they decremented to 0x0 since they were previously set to 0xF.

Programming Note

A Hypervisor Decrementer exception is not created if the thread is in a power-saving mode when HDEC₃₂ changes from 0 to 1 because having a Hypervisor Decrementer interrupt occur almost immediately after exiting the power-saving mode in this case is deemed unnecessary. The hypervisor already has control, and if a timed exit from the power-saving mode is necessary and possible, the hypervisor can use the Decrementer to exit the power-saving mode at the appropriate time. For sleep and rvinkle power-saving levels, the state of the Hypervisor Decrementer and Decrementer is not necessarily maintained and updated.

which the PURR value increases is implementation dependent.

Let the difference between the value represented by the contents of the Time Base at times T_a and T_b be T_{ab} . Let the difference between the value represented by the contents of the PURR at time T_a and T_b be the value P_{ab} . The ratio of P_{ab}/T_{ab} is an estimate of the percentage of shared resources used by the thread during the interval T_{ab} . For the set $\{S\}$ of threads that share the resources monitored by the PURR, the sum of the usage estimates for all the threads in the set is 1.0.

The definition of the set of threads S , the shared resources corresponding to the set S , and specifics of the algorithm for incrementing the PURR are implementation-specific.

The PURR is implemented such that:

1. Loading a GPR from the PURR has no effect on the accuracy of the PURR.
2. Copying the contents of a GPR to the PURR replaces the contents of the PURR with the contents of the GPR.

Programming Note

Estimates computed as described above may be useful for purposes related to resource utilization, including utilization-based system management and planning.

Because the rate at which the PURR accumulates resource usage estimates is dependent on the frequency at which the Time Base is incremented, and the frequency of the oscillator that drives instruction execution may vary independently from that of the Time Base, the interpretation of the contents of the PURR may be inaccurate as a measurement of capacity consumption for accounting purposes. The SPURR should be used for accounting purposes.

7.5 Processor Utilization of Resources Register (PURR)

The Processor Utilization of Resources Register (PURR) is a 64-bit counter, the contents of which provide an estimate of the resources used by the thread. The contents of the PURR are treated as a 64-bit unsigned integer.

Figure 49. Processor Utilization of Resources Register

The PURR is a hypervisor resource; see Chapter 2.

The contents of the PURR increase monotonically, unless altered by software, until the sum of the contents plus the amount by which it is to be increased exceed 0xFFFF_FFFF_FFFF_FFFF ($2^{64} - 1$) at which point the contents are replaced by that sum modulo 2^{64} . There is no interrupt or other indication when this occurs.

The rate at which the value represented by the contents of the PURR increases is an estimate of the portion of resources used by the thread per unit time with respect to other threads that share those resources monitored by the PURR. When the thread is idle, the rate at

7.6 Scaled Processor Utilization of Resources Register (SPURR)

The Scaled Processor Utilization of Resources Register (SPURR) is a 64-bit counter, the contents of which provide an estimate of the resources used by the thread. The contents of the SPURR are treated as a 64-bit unsigned integer.

Figure 50. Scaled Processor Utilization of Resources Register

The SPURR is a hypervisor resource; see Section 2.7.

The contents of the SPURR increase monotonically, unless altered by software, until the sum of the contents plus the amount by which it is to be increased exceed $0xFFFF_FFFF_FFFF_FFFF$ ($2^{64} - 1$) at which point the contents are replaced by that sum modulo 2^{64} . There is no interrupt or other indication when this occurs.

The rate at which the value represented by the contents of the SPURR increases is an estimate of the portion of resources used by the thread with respect to other threads that share those resources monitored by the SPURR, and relative to the computational capacity provided by those resources. The computational capacity provided by the shared resources may vary as a function of the frequency of the oscillator which drives the resources or as a result of deliberate delays in processing that are created to reduce power consumption. When the thread is idle, the rate at which the SPURR value increases is implementation dependent.

Let the difference between the value represented by the contents of the Time Base at times T_a and T_b be T_{ab} . Let the ratio of the effective and nominal frequencies of the oscillator driving instruction execution f_e/f_n be f_r . Let the ratio of delay cycles created by power reduction circuitry and total cycles c_d/c_t be c_r . Let the difference between the value represented by the contents of the SPURR at time T_a and T_b be the value S_{ab} . The ratio of $S_{ab}/(T_{ab} \times f_r \times (1 - c_r))$ is an estimate of the percentage of shared resource capacity used by the thread during the interval T_{ab} . For the set $\{S\}$ of threads that share the resources monitored by the SPURR, the sum of the usage estimates for all the threads in the set is 1.0.

The definition of the set of threads S , the shared resources corresponding to the set S , and specifics of the algorithm for incrementing the SPURR are implementation-specific.

The SPURR is implemented such that:

1. Loading a GPR from the SPURR has no effect on the accuracy of the SPURR.
2. Copying the contents of a GPR to the SPURR replaces the contents of the SPURR with the contents of the GPR.

Programming Note

Estimates computed as described above may be useful for purposes of resource use accounting, program dispatching, etc.

Chapter 8. Debug Facilities

8.1 Overview	855	8.1.2 Data Address Breakpoint	855
8.1.1 Come-From Address Register . .	855		

8.1 Overview

Implementations provide debug facilities to enable hardware and software debug functions, such as control flow tracing, data address breakpoints, and program single-stepping. The debug facilities described in this section consist of the Come-From Address Register (see Section 8.1.1), and the Data Address Breakpoint Register (DABR) and Data Address Breakpoint Register Extension (DABRX) (see Section 8.1.2). The interrupt associated with the Data Address Breakpoint registers is described in Section 6.5.3. The Trace facility, which can be used for single-stepping as well as for control flow tracing, is described in Section 6.5.14.

The *mfspr* and *mtspr* instructions (see Section 4.4.4) provide access to the registers of the debug facilities.

In addition to the facilities mentioned above, implementations typically provide debug facilities, modes, and access mechanisms that are implementation-specific. For example, implementations typically provide facilities for instruction address tracing, and also access to certain debug facilities via a dedicated interface such as the IEEE 1149.1 Test Access Port (JTAG).

8.1.1 Come-From Address Register

The Come-From Address Register (CFAR) is a 64-bit register. When an *rfd* instruction is executed, the register is set to the effective address of the instruction. When a *Branch* instruction is executed and the branch is taken, the register is set to the effective address of an instruction in the instruction cache block containing the *Branch* instruction, except that if the *Branch* instruction is a B-form *Branch* (i.e. *bc*, *bca*, *bcl*, or *bcla*) for which the target address is in the instruction cache block containing the *Branch* instruction or is in the previous or next cache block, the register is not necessarily set. For *Branch* instructions, the setting need not occur until

a subsequent context synchronizing operation has occurred.

Figure 51. Come-From Address Register

The contents of the CFAR can be read and written using the *mfspr* and *mtspr* instructions. Access to the CFAR is privileged.

Programming Note

This register can be used for purposes of debugging software. For example, often a software bug results in the program executing a portion of the code that it should not have reached or causing an unexpected interrupt. In the former case, a breakpoint can be placed in the portion of the code that was erroneously reached and the program reexecuted. In either case, the interrupt handler can save the contents of the CFAR (before executing the first instruction that would modify the register), and then make the saved contents available for a debugger to use in determining the control flow path by which the exception was reached.

In order to preserve the CFAR's contents for each partition and to prevent it from being used to implement a "covert channel" between partitions, the hypervisor should initialize/save/restore the CFAR when switching partitions on a given thread.

8.1.2 Data Address Breakpoint

The Data Address Breakpoint mechanism provides a means of detecting load and store accesses to a designated doubleword. The address comparison is done on an effective address (EA).

The Data Address Breakpoint mechanism is controlled by the Data Address Breakpoint Register (DABR),

shown in Figure 52, and the Data Address Breakpoint Register Extension (DABRX), shown in Figure 53.

Bit(s)	Name	Description
0:60	DAB	Data Address Breakpoint
61	BT	Breakpoint Translation
62	DW	Data Write
63	DR	Data Read

Figure 52. Data Address Breakpoint Register

Bit(s)	Name	Description
60	BTI	Breakpoint Translation Ignore
61:63	PRIVM	Privilege Mask
61	HYP	Hypervisor state
62	PNH	Privileged but Non-Hypervisor state
63	PRO	Problem state

All other fields are reserved.

Figure 53. Data Address Breakpoint Register Extension

The DABR and DABRX are hypervisor resources; see Section 2.7 on page 737.

The supported PRIVM values are 0b000, 0b001, 0b010, 0b011, 0b100, and 0b111. If the PRIVM field does not contain one of the supported values, then whether a match occurs for a given storage access is undefined. Elsewhere in this section it is assumed that the PRIVM field contains one of the supported values.

Programming Note

PRIVM value 0b000 causes matches not to occur regardless of the contents of other DABR and DABRX fields. PRIVM values 0b101 and 0b110 are not supported because a storage location that is shared between the hypervisor and non-hypervisor software is unlikely to be accessed using the same EA by both the hypervisor and the non-hypervisor software. (PRIVM value 0b111 is supported primarily for reasons of software compatibility, as described in a subsequent Programming Note.)

A Data Address Breakpoint match occurs for a Load or Store instruction if, for any byte accessed, all of the following conditions are satisfied.

- the access is
 - a quadword access and $EA_{0:59} = DABR_{0:59}$, or
 - not a quadword access and $EA_{0:60} = DABR_{0:60} (= DABR_{DAB})$
- $(MSR_{DR} = DABR_{BT}) \mid DABRX_{BTI}$
- the thread is in

- hypervisor state and $DABRX_{HYP} = 1$, or
- privileged but non-hypervisor state and $DABRX_{PNH} = 1$, or
- problem state and $DABRX_{PR} = 1$
- the instruction is a *Store* and $DABR_{DW} = 1$, or the instruction is a *Load* and $DABR_{DR} = 1$.

In 32-bit mode the high-order 32 bits of the EA are treated as zeros for the purpose of detecting a match.

If the above conditions are satisfied, a match also occurs for *eciwx* and *ecowx*. For the purpose of determining whether a match occurs, *eciwx* is treated as a *Load*, and *ecowx* is treated as a *Store*.

If the above conditions are satisfied, it is undefined whether a match occurs in the following cases.

- The instruction is *Store Conditional* but the store is not performed
- The instruction is *dcbz*. (For the purpose of determining whether a match occurs, *dcbz* is treated as a *Store*.)

The *Cache Management* instructions other than *dcbz* never cause a match.

A Data Address Breakpoint match causes a Data Storage exception or a Hypervisor Data Storage exception (see Section 6.5.3, “Data Storage Interrupt” on page 832 and Section 6.5.15, “Hypervisor Data Storage Interrupt” on page 840). If a match occurs, some or all of the bytes of the storage operand may have been accessed; however, if a *Store* or *ecowx* instruction causes the match, the storage operand is not modified if the instruction is one of the following:

- any *Store* instruction that causes an atomic access
- *ecowx*

Programming Note

The Data Address Breakpoint mechanism does not apply to instruction fetches.

Programming Note

Before setting a breakpoint requested by the operating system, the hypervisor must verify that the requested contents of the DABR and DABRX cannot cause the hypervisor to receive a Data Storage interrupt that it is not prepared to handle, or that it intrinsically cannot handle (e.g., the EA is in the range of EAs at which the hypervisor's Data Storage interrupt handler saves registers, $DABR_{BT} \mid DABRX_{BTI} \neq 0b10$, $DABR_{DW} = 1$, and $DABRX_{HYP} = 1$).

Programming Note

Implementations that comply with versions of the architecture that precede Version 2.02 do not provide the DABRX. Forward compatibility for software that was written for such implementations (and uses the Data Address Breakpoint facility) can be obtained by setting $DABRX_{60:63}$ to 0b0111.

Chapter 9. External Control [Category: External Control]

The External Control facility permits a program to communicate with a special-purpose device. The facility consists of a Special Purpose Register, called EAR, and two instructions, called *External Control In Word Indexed (eciwx)* and *External Control Out Word Indexed (ecowx)*.

This facility must provide a means of synchronizing the devices with the hardware to prevent the use of an address by the device when the translation that produced that address is being invalidated.

9.1 External Access Register

This 32-bit Special Purpose Register controls access to the External Control facility and, for external control operations that are permitted, identifies the target device.

Bit(s)	Name	Description
32	E	Enable bit
58:63	RID	Resource ID

All other fields are reserved.

Figure 54. External Access Register

The External Access Register (EAR) is a hypervisor resource; see Chapter 2.

The high-order bits of the RID field that correspond to bits of the Resource ID beyond the width of the Resource ID supported by the implementation are treated as reserved bits.

Programming Note

The hypervisor can use the EAR to control which programs are allowed to execute *External Access* instructions, when they are allowed to do so, and which devices they are allowed to communicate with using these instructions.

9.2 External Access Instructions

The *External Access* instructions, *External Control In Word Indexed (eciwx)* and *External Control Out Word Indexed (ecowx)*, are described in Book II. Additional information about them is given below.

If attempt is made to execute either of these instructions when $\text{EAR}_E=0$, a Data Storage interrupt occurs with bit 43 of the DSISR set to 1.

The instructions are supported whenever $\text{MSR}_{DR}=1$. If either instruction is executed when $\text{MSR}_{DR}=0$ (real addressing mode), the results are boundedly undefined.

Chapter 10. Synchronization Requirements for Context Alterations

Changing the contents of certain System Registers, the contents of SLB entries, or the contents of other system resources that control the context in which a program executes can have the side effect of altering the context in which data addresses and instruction addresses are interpreted, and in which instructions are executed and data accesses are performed. For example, changing MSR_{IP} from 0 to 1 has the side effect of enabling translation of instruction addresses. These side effects need not occur in program order, and therefore may require explicit synchronization by software. (Program order is defined in Book II.)

An instruction that alters the context in which data addresses or instruction addresses are interpreted, or in which instructions are executed or data accesses are performed, is called a *context-altering instruction*. This chapter covers all the context-altering instructions. The software synchronization required for them is shown in Table 1 (for data access) and Table 2 (for instruction fetch and execution).

The notation “CSI” in the tables means any context synchronizing instruction (e.g., *sc*, *isync*, or *rfid*). A context synchronizing interrupt (i.e., any interrupt except non-recoverable System Reset or non-recoverable Machine Check) can be used instead of a context synchronizing instruction. If it is, phrases like “the synchronizing instruction”, below, should be interpreted as meaning the instruction at which the interrupt occurs. If no software synchronization is required before (after) a context-altering instruction, “the synchronizing instruction before (after) the context-altering instruction” should be interpreted as meaning the context-altering instruction itself.

The synchronizing instruction before the context-altering instruction ensures that all instructions up to and including that synchronizing instruction are fetched and executed in the context that existed before the alteration. The synchronizing instruction after the context-altering instruction ensures that all instructions after that synchronizing instruction are fetched and executed in the context established by the alteration. Instructions after the first synchronizing instruction, up to and including the second synchronizing instruction, may be fetched or executed in either context.

If a sequence of instructions contains context-altering instructions and contains no instructions that are affected by any of the context alterations, no software synchronization is required within the sequence.

Programming Note

Sometimes advantage can be taken of the fact that certain events, such as interrupts, and certain instructions that occur naturally in the program, such as the *rfid* that returns from an interrupt handler, provide the required synchronization.

No software synchronization is required before or after a context-altering instruction that is also context synchronizing or when altering the MSR in most cases (see the tables). No software synchronization is required before most of the other alterations shown in Table 2, because all instructions preceding the context-altering instruction are fetched and decoded before the context-altering instruction is executed (the hardware must determine whether any of these preceding instructions are context synchronizing).

Unless otherwise stated, the material in this chapter assumes a single-threaded environment.

Table 2: Synchronization requirements for instruction fetch and/or execution

Notes:

1. The effect of changing the EE bit is immediate, even if the *mtmsr[d]* instruction is not context synchronizing (i.e., even if L=1).
 - If an *mtmsr[d]* instruction sets the EE bit to 0, neither an External interrupt nor a Decrementer interrupt occurs after the *mtmsr[d]* is executed.
 - If an *mtmsr[d]* instruction changes the EE bit from 0 to 1 when an External, Decrementer, or higher priority exception exists, the corresponding interrupt occurs immediately after the *mtmsr[d]* is executed, and before the next instruction is executed in the program that set EE to 1.
 - If a hypervisor executes the *mtmsr[d]* instruction that sets the EE bit to 0, a Hypervisor Decrementer interrupt does not occur after *mtmsr[d]* is executed as long as the thread remains in hypervisor state.
 - If the hypervisor executes an *mtmsr[d]* instruction that changes the EE bit from 0 to 1 when a Hypervisor Decrementer or higher priority exception exists, the corresponding interrupt occurs immediately after the *mtmsr[d]* instruction is executed, and before the next instruction is executed, provided HDICE is 1.
2. Synchronization requirements for this instruction are implementation-dependent.
3. SDR1 must not be altered when $MSR_{DR}=1$ or $MSR_{IR}=1$; if it is, the results are undefined.
4. A *ptesync* instruction is required before the *mtspr* instruction because (a) SDR1 identifies the Page Table and thereby the location of Reference and Change bits, and (b) on some implementations, use of SDR1 to update Reference and Change bits may be independent of translating the virtual address. (For example, an implementation might identify the PTE in which to update the Reference and Change bits in terms of its offset in the Page Table, instead of its real address, and then add the Page Table address from SDR1 to the offset to determine the real address at which to update the bits.) To ensure that Reference and Change bits are updated in the correct Page Table, SDR1 must not be altered until all Reference and Change bit updates associated with address translations that were performed, by the thread executing the *mtspr* instruction, before the *mtspr* instruction is executed have been performed with respect to that thread. A *ptesync* instruction guarantees this synchronization of Reference and Change bit updates, while neither a context synchronizing operation nor the instruction fetching mechanism does so.
5. For data accesses, the context synchronizing instruction before the *tlbie*, *tlbiel*, or *tlbia* instruc-

tion ensures that all preceding instructions that access data storage have completed to a point at which they have reported all exceptions they will cause.

The context synchronizing instruction after the *tlbie*, *tlbiel*, or *tlbia* instruction ensures that storage accesses associated with instructions following the context synchronizing instruction will not use the TLB entry(s) being invalidated.

(If it is necessary to order storage accesses associated with preceding instructions, or Reference and Change bit updates associated with preceding address translations, with respect to subsequent data accesses, a *ptesync* instruction must also be used, either before or after the *tlbie*, *tlbiel*, or *tlbia* instruction. These effects of the *ptesync* instruction are described in the last paragraph of Note 8.)

6. The notation “{*ptesync*,CSI}” denotes an instruction sequence. Other instructions may be interleaved with this sequence, but these instructions must appear in the order shown.

No software synchronization is required before the *Store* instruction because (a) stores are not performed out-of-order and (b) address translations associated with instructions preceding the *Store* instruction are not performed again after the store has been performed (see Section 5.5). These properties ensure that all address translations associated with instructions preceding the *Store* instruction will be performed using the old contents of the PTE.

The *ptesync* instruction after the *Store* instruction ensures that all searches of the Page Table that are performed after the *ptesync* instruction completes will use the value stored (or a value stored subsequently). The context synchronizing instruction after the *ptesync* instruction ensures that any address translations associated with instructions following the context synchronizing instruction that were performed using the old contents of the PTE will be discarded, with the result that these address translations will be performed again and, if there is no corresponding entry in any implementation-specific address translation lookaside information, will use the value stored (or a value stored subsequently).

The *ptesync* instruction also ensures that all storage accesses associated with instructions preceding the *ptesync* instruction, and all Reference and Change bit updates associated with additional address translations that were performed, by the thread executing the *ptesync* instruction, before the *ptesync* instruction is executed, will be performed with respect to any thread or mechanism, to the extent required by the associated Memory Coherence Required attributes, before any data accesses caused by instructions following the *pte-*

sync instruction are performed with respect to that thread or mechanism.

- There are additional software synchronization requirements for this instruction in multi-threaded environments (e.g., it may be necessary to invalidate one or more TLB entries on all threads in the system and to be able to determine that the invalidations have completed and that all side effects of the invalidations have taken effect).

Section 5.10 gives examples of using **tlbie**, **Store**, and related instructions to maintain the Page Table, in both multi-threaded environments and environments consisting of only a single-threaded processor.

Programming Note

In a multi-threaded system, if software locking is used to help ensure that the requirements described in Section 5.10 are satisfied, the **lwsync** instruction near the end of the lock acquisition sequence (see Section B.2.1.1 of Book II) may naturally provide the context synchronization that is required before the alteration.

- The alteration must not cause an implicit branch in effective address space. Thus, when changing MSR_{SF} from 1 to 0, the **mtmsrd** instruction must have an effective address that is less than $2^{32} - 4$. Furthermore, when changing MSR_{SF} from 0 to 1, the **mtmsrd** instruction must not be at effective address $2^{32} - 4$ (see Section 5.3.2 on page 770).
- The alteration must not cause an implicit branch in real address space. Thus the real address of the context-altering instruction and of each subsequent instruction, up to and including the next context synchronizing instruction, must be independent of whether the alteration has taken effect.

Programming Note

If it is desired to set MSR_{IR} to 1 early in an operating system interrupt handler, advantage can sometimes be taken of the fact that $EA_{0:3}$ are ignored when forming the real address when address translation is disabled and $MSR_{HV} = 0$. For example, if address translation resources are set such that effective address $0xn000_0000_0000_0000$ maps to real address $0x000_0000_0000_0000$ when address translation is enabled, where n is an arbitrary 4-bit value, the following code sequence, in real page 0, can be used early in the interrupt handler.

```

la      rx,target
li      ry,0xn000
sldi   ry,ry,48
or      rx,rx,ry # set high-order
                    nibble of target
                    addr to 0xn

mtctr  rx
bcctr  # branch to targ

targ:  mfmsr  rx
        ori   rx,rx,0x0020
        mtmsrd rx# set MSR[IR] to 1

```

The **mtmsrd** does not cause an implicit branch in real address space because the real address of the next sequential instruction is independent of MSR_{IR} . Using **mtmsrd**, rather than **rfid** (or similar context synchronizing instruction that alters the control flow), may yield better performance on some implementations.

(Variations on the technique are possible. For example, the target instruction of the **bcctr** can be in arbitrary real page P , where P is a 48-bit value, provided that effective address $0xn \parallel P \parallel 0x000$ maps to real address $P \parallel 0x000$ when address translation is enabled.)

- The elapsed time between the contents of the Decrementer or Hypervisor Decrementer becoming negative and the signaling of the corresponding exception is not defined.
- If an **slbmtc** instruction alters the mapping, or associated attributes, of a currently mapped ESID, the **slbmtc** must be preceded by an **slbie** (or **slbia**) instruction that invalidates the existing translation. This applies even if the corresponding entry is no longer in the SLB (the translation may still be in implementation-specific address translation lookaside information). No software synchronization is needed between the **slbie** and the **slbmtc**, regardless of whether the index of the SLB entry (if any) containing the current translation is the same as the SLB index specified by the **slbmtc**.

No *slbie* (or *slbia*) is needed if the *slbmtc* instruction replaces a valid SLB entry with a mapping of a different ESID (e.g., to satisfy an SLB miss). However, the *slbie* is needed later if and when the translation that was contained in the replaced SLB entry is to be invalidated.

12. The context synchronizing instruction before the *mtspr* instruction ensures that the LPIDR is not altered out-of-order. (Out-of-order alteration of the LPIDR could permit the requirements described in Section 5.10.1 to be violated. For the same reason, such a context synchronizing instruction may be needed even if the new LPID value is equal to the old LPID value.)

See also Chapter 2. “Logical Partitioning (LPAR)” on page 731 regarding moving a thread from one partition to another.

13. When the RMOR or HRMOR is modified, or the VC, VRMASD, RMLS, or LPES₁ fields of the LPCR are modified, software must invalidate all implementation-specific lookaside information used in address translation that depends on the old contents of these registers or fields (i.e., the contents immediately before the modification). The *slbia* instruction can be used to invalidate all such implementation-specific lookaside information.
14. A context synchronizing instruction or event that is executed or occurs when LPCR_{MER} = 1 does not necessarily ensure that the exception effects of LPCR_{MER} are consistent with the contents of LPCR_{MER}. See Section 2.2.
15. This line applies regardless of which SPR number (13 or 29) is used for the AMR.

16. LPIDR must not be altered when MSR_{DR}=0 or MSR_{IR}=0; if it is, the results are undefined.

Appendix A. Assembler Extended Mnemonics

In order to make assembler language programs simpler to write and easier to understand, a set of extended mnemonics and symbols is provided for certain instruc-

tions. This appendix defines extended mnemonics and symbols related to instructions defined in Book III.

Assemblers should provide the extended mnemonics and symbols listed here, and may provide others.

A.1 Move To/From Special Purpose Register Mnemonics

This section defines extended mnemonics for the *mtspr* and *mfspir* instructions, including the Special Purpose Registers (SPRs) defined in Book I and certain privileged SPRs, and for the *Move From Time Base* instruction defined in Book II.

The *mtspr* and *mfspir* instructions specify an SPR as a numeric operand; extended mnemonics are provided that represent the SPR in the mnemonic rather than requiring it to be coded as an operand. Similar extended mnemonics are provided for the *Move From Time Base* instruction, which specifies the portion of the Time Base as a numeric operand.

Note: *mftb* serves as both a basic and an extended mnemonic. The Assembler will recognize an *mftb* mnemonic with two operands as the basic form, and an

mftb mnemonic with one operand as the extended form. In the extended form the TBR operand is omitted and assumed to be 268 (the value that corresponds to TB).

Programming Note

The extended mnemonics in Table 3 for SPRs associated with the Performance Monitor facility are based on the definitions in Appendix B.

Other versions of Performance Monitor facilities used different sets of SPR numbers (all 32-bit PowerPC implementations used a different set, and some early Power ISA implementations used yet a different set).

¹ The *mftb* instruction is Category: Phased-Out. Assemblers targeting version 2.03 or later of the architecture should generate an *mfspir* instruction for the *mftb* and *mftbu* extended mnemonics; see the corresponding Assembler Note in the *mftb* instruction description (see Section 5.2.1 of Book II).

² Category: Phased-In

Appendix B. Example Performance Monitor

Note

This Appendix describes an example implementation of a Performance Monitor. A subset of these requirements are being considered for inclusion in the Architecture as part of Category: Server.Performance Monitor.

A Performance Monitor facility provides a means of collecting information about program and system performance.

The resources (e.g., SPR numbers) that a Performance Monitor facility may use are identified elsewhere in this Book. All other aspects of any Performance Monitor facility are implementation-dependent.

This appendix provides an example of a Performance Monitor facility. It is only an example; implementations may provide all, some, or none of the features described here, or may provide features that are similar to those described here but differ in detail.

Programming Note

Because the features provided by a Performance Monitor facility are implementation-dependent, operating systems should provide services that support the useful performance monitoring functions in a generic fashion. Application programs should use these services, and should not depend on the features provided by a particular implementation.

The example Performance Monitor facility consists of the following features (described in detail in subsequent sections).

- one MSR bit
 - PMM (Performance Monitor Mark), which can be used to select one or more programs for monitoring
- SPRs
 - PMC1 - PMC6 (Performance Monitor Counter registers 1 - 6), which count events
 - MMCR0, MMCR1, and MMCR A (Monitor Mode Control Registers 0, 1, and A), which control the Performance Monitor facility

- SIAR and SDAR (Sampled Instruction Address Register and Sampled Data Address Register), which contain the address of the “sampled instruction” and of the “sampled data”

- the Performance Monitor interrupt, which can be caused by monitored conditions and events

The minimal subset of the features that makes the resulting Performance Monitor useful to software consists of MSR_{PMM}, PMC1, PMC2, PMC3, PMC4, MMCR0, MMCR1, and MMCR A and certain bits and fields of these three Monitor Mode Control Registers, and the Performance Monitor Interrupt. These features are identified as the “basic” features below. The remaining features (the remaining SPRs, and the remaining bits and fields in the three Monitor Mode Control Registers) are considered “extensions”.

The events that can be counted in the PMCs as well as the code that identifies each event are implementation-dependent. The events and codes may vary between PMCs, as well as between implementations. For the programmable PMCs, the event to be counted is selected by specifying the appropriate code in the MMCR “Selector” field for the PMC. Some events may include operations that are performed out-of-order.

Many aspects of the operation of the Performance Monitor are summarized by the following hierarchy, which is described starting at the lowest level.

- A “counter negative condition” exists when the value in a PMC is negative (i.e., when bit 0 of the PMC is 1). A “Time Base transition event” occurs when a selected bit of the Time Base changes from 0 to 1 (the bit is selected by an MMCR field). The term “condition or event” is used as an abbreviation for “counter negative condition or Time Base transition event”. A condition or event can be caused implicitly by the hardware (e.g., incrementing a PMC) or explicitly by software (*mtspr*).
- A condition or event is enabled if the corresponding “Enable” bit in an MMCR is 1. The occurrence of an enabled condition or event can have side effects within the Performance Monitor, such as causing the PMCs to cease counting.
- An enabled condition or event causes a Performance Monitor alert if Performance Monitor alerts are enabled by the corresponding “Enable” bit in

an MMCR. A single Performance Monitor alert may reflect multiple enabled conditions and events.

- A Performance Monitor alert causes a Performance Monitor exception.

The exception effects of the Performance Monitor are said to be consistent with the contents of $MMCR0_{PMAO}$ if one of the following statements is true. ($MMCR0_{PMAO}$ reflects the occurrence of Performance Monitor alerts; see the definition of that bit in Section B.2.2.)

- $MMCR0_{PMAO}=0$ and a Performance Monitor exception does not exist.
- $MMCR0_{PMAO}=1$ and a Performance Monitor exception exists.

A context synchronizing instruction or event that occurs when $MMCR0_{PMAO}=0$ ensures that the exception effects of the Performance Monitor are consistent with the contents of $MMCR0_{PMAO}$.

Even without software synchronization, when the contents of $MMCR0_{PMAO}$ change, the exception effects of the Performance Monitor become consistent with the new contents of $MMCR0_{PMAO}$ sufficiently soon that the Performance Monitor facility is useful to software for its intended purposes.

- A Performance Monitor exception causes a Performance Monitor interrupt when $MSR_{EE}=1$.

Programming Note

The Performance Monitor can be effectively disabled (i.e., put into a state in which Performance Monitor SPRs are not altered and Performance Monitor interrupts do not occur) by setting $MMCR0$ to $0x0000_0000_8000_0000$.

B.1 PMM Bit of the Machine State Register

The Performance Monitor uses MSR bit PMM, which is defined as follows.

Bit	Description
61	Performance Monitor Mark (PMM) This bit is a basic feature. This bit contains the Performance Monitor “mark” (0 or 1).

Programming Note

Software can use this bit as a process-specific marker which, in conjunction with $MMCR0_{FCM0}$ $FCM1$ (see Section B.2.2), permits events to be counted on a process-specific basis. (The bit is saved by interrupts and restored by *rfid*.)

Common uses of the PMM bit include the following.

- Count events for a few selected processes. This use requires the following bit settings.
 - $MSR_{PMM}=1$ for the selected processes, $MSR_{PMM}=0$ for all other processes
 - $MMCR0_{FCM0}=1$
 - $MMCR0_{FCM1}=0$
- Count events for all but a few selected processes. This use requires the following bit settings.
 - $MSR_{PMM}=1$ for the selected processes, $MSR_{PMM}=0$ for all other processes
 - $MMCR0_{FCM0}=0$
 - $MMCR0_{FCM1}=1$

Notice that for both of these uses a mark value of 1 identifies the “few” processes and a mark value of 0 identifies the remaining “many” processes. Because the PMM bit is set to 0 when an interrupt occurs (see Figure 44 on page 828), interrupt handlers are treated as one of the “many”. If it is desired to treat interrupt handlers as one of the “few”, the mark value convention just described would be reversed.

B.2 Special Purpose Registers

The Performance Monitor SPRs count events, control the operation of the Performance Monitor, and provide associated information.

The Performance Monitor SPRs can be read and written using the *mfspr* and *mtspr* instructions (see Section 4.4.4, “Move To/From System Register Instructions” on page 760). The Performance Monitor SPR numbers are shown in Figure 55. Writing any of the Performance Monitor SPRs is privileged. Reading any of the Performance Monitor SPRs is *not* privileged (however, the privileged SPR numbers used to write the SPRs can also be used to read them; see the figure).

The elapsed time between the execution of an instruction and the time at which events due to that instruction have been reflected in Performance Monitor SPRs is not defined. No means are provided by which software can ensure that all events due to preceding instructions have been reflected in Performance Monitor SPRs. Similarly, if the events being monitored may be caused by operations that are performed out-of-order, no means are provided by which software can prevent such events due to subsequent instructions from being

reflected in Performance Monitor SPRs. Thus the contents obtained by reading a Performance Monitor SPR may not be precise: it may fail to reflect some events due to instructions that precede the *mf spr* and may reflect some events due to instructions that follow the *mf spr*. This lack of precision applies regardless of whether the state of the thread is such that the SPR is subject to change by the hardware at the time the *mf spr* is executed. Similarly, if an *mt spr* instruction is executed that changes the contents of the Time Base, the change is not guaranteed to have taken effect with respect to causing Time Base transition events until after a subsequent context synchronizing instruction has been executed.

If an *mt spr* instruction is executed that changes the value of a Performance Monitor SPR other than SIAR or SDAR, the change is not guaranteed to have taken effect until after a subsequent context synchronizing instruction has been executed (see Chapter 10. “Synchronization Requirements for Context Alterations” on page 861).

Programming Note

Depending on the events being monitored, the contents of Performance Monitor SPRs may be affected by aspects of the runtime environment (e.g., cache contents) that are not directly attributable to the programs being monitored.

decimal	SPR ^{1,2}		Register Name	Privileged
	spr _{5:9}	spr _{0:4}		
770,786	11000	n0010	MMCR0	no,yes

B.2.1 Performance Monitor Counter Registers

The six Performance Monitor Counter registers, PMC1 through PMC6, are 32-bit registers that count events.

Figure 57. Performance Monitor Counter registers

PMC1, PMC2, PMC3, and PMC4 are basic features. PMC5 and PMC6 are not programmable. PMC5 counts instructions completed and PMC6 counts cycles.

Normally each PMC is incremented each hardware cycle by the number of times the corresponding event occurred in that cycle. Other modes of incrementing may also be provided (e.g., see the description of MMCR1 bits PMC1HIST and PMCjHIST).

“PMCj” is used as an abbreviation for “PMC_i, i > 1”.

Programming Note

PMC5 and PMC6 are defined to facilitate calculating basic performance metrics such as cycles per instruction (CPI).

Programming Note

Software can use a PMC to “pace” the collection of Performance Monitor data. For example, if it is desired to collect event counts every n cycles, software can specify that a particular PMC count cycles and set that PMC to $0x8000_0000 - n$. The events of interest would be counted in other PMCs. The counter negative condition that will occur after n cycles can, with the appropriate setting of MMCR bits, cause counter values to become frozen, cause a Performance Monitor interrupt to occur, etc.

B.2.2 Monitor Mode Control Register 0

Monitor Mode Control Register 0 (MMCR0) is a 64-bit register. This register, along with MMCR1 and MMCR2, controls the operation of the Performance Monitor.

Figure 58. Monitor Mode Control Register 0

MMCR0 is a basic feature. Within MMCR0, some of the bits and fields are basic features and some are extensions. The basic bits and fields are identified as such, below.

Some bits of MMCR0 are altered by the hardware when various events occur, as described below.

The bit definitions of MMCR0 are as follows. MMCR0 bits that are not implemented are treated as reserved.

Bit(s)	Description
0:31	Reserved
32	Freeze Counters (FC) This bit is a basic feature. 0 The PMCs are incremented (if permitted by other MMCR bits). 1 The PMCs are not incremented.
33	Freeze Counters in Privileged State (FCS) This bit is a basic feature. 0 The PMCs are incremented (if permitted by other MMCR bits). 1 The PMCs are not incremented if $MSR_{HV_PR}=0b00$.
34	Freeze Counters in Problem State (FCP) This bit is a basic feature.
35	Freeze Counters while Mark = 1 (FCM1) This bit is a basic feature. 0 The PMCs are incremented (if permitted by other MMCR bits). 1 The PMCs are not incremented if $MSR_{PR}=1$.
36	Freeze Counters while Mark = 0 (FCM0) This bit is a basic feature. 0 The PMCs are incremented (if permitted by other MMCR bits). 1 The PMCs are not incremented if $MSR_{PMM}=0$.
37	Performance Monitor Alert Enable (PMAE) This bit is a basic feature. 0 Performance Monitor alerts are disabled. 1 Performance Monitor alerts are enabled until a Performance Monitor alert occurs, at which time: ■ $MMCR0_{PMAE}$ is set to 0 ■ $MMCR0_{PMAO}$ is set to 1
38	Freeze Counters on Enabled Condition or Event (FCECE) 0 The PMCs are incremented (if permitted by other MMCR bits). 1 The PMCs are incremented (if permitted by other MMCR bits) until an enabled condition or event occurs when $MMCR0_{TRIGGER}=0$, at which time: ■ $MMCR0_{FC}$ is set to 1 If the enabled condition or event occurs when $MMCR0_{TRIGGER}=1$, the FCECE bit is treated as if it were 0.
39:40	Time Base Selector (TBSEL)

Programming Note

Software can set this bit and $MMCR0_{PMAO}$ to 0 to prevent Performance Monitor interrupts.

Software can set this bit to 1 and then poll the bit to determine whether an enabled condition or event has occurred. This is especially useful for software that runs with $MSR_{EE}=0$.

In earlier versions of the architecture that lacked the concept of Performance Monitor alerts, this bit was called Performance Monitor Exception Enable (PMXE).

This field selects the Time Base bit that can cause a Time Base transition event (the event occurs when the selected bit changes from 0 to 1).

- 00 Time Base bit 63 is selected.
- 01 Time Base bit 55 is selected.
- 10 Time Base bit 51 is selected.
- 11 Time Base bit 47 is selected.

Programming Note

Time Base transition events can be used to collect information about activity, as revealed by event counts in PMCs and by addresses in SIAR and SDAR, at periodic intervals.

In multi-threaded systems in which the Time Base registers are synchronized among the threads, Time Base transition events can be used to correlate the Performance Monitor data obtained by the several threads. For this use, software must specify the same TBSEL value for all the threads in the system.

Because the frequency of the Time Base is implementation-dependent, software should invoke a system service program to obtain the frequency before choosing a value for TBSEL.

- 41 **Time Base Event Enable** (TBEE)
- 0 Time Base transition events are disabled.
 - 1 Time Base transition events are enabled.
- 42:47 Reserved
- 48 **PMC1 Condition Enable** (PMC1CE)
- This bit controls whether counter negative conditions due to a negative value in PMC1 are enabled.
- 0 Counter negative conditions for PMC1 are disabled.
 - 1 Counter negative conditions for PMC1 are enabled.
- 49 **PMCj Condition Enable** (PMCjCE)
- This bit controls whether counter negative conditions due to a negative value in any PMCj (i.e., in any PMC except PMC1) are enabled.
- 0 Counter negative conditions for all PMCjs are disabled.
 - 1 Counter negative conditions for all PMCjs are enabled.
- 50 **Trigger** (TRIGGER)
- 0 The PMCs are incremented (if permitted by other MMCR bits).

- 1 PMC1 is incremented (if permitted by other MMCR bits). The PMCs are not incremented until PMC1 is negative or an enabled condition or event occurs, at which time:

- the PMCs resume incrementing (if permitted by other MMCR bits)
- MMCR0_{TRIGGER} is set to 0

See the description of the FCECE bit, above, regarding the interaction between TRIGGER and FCECE.

Programming Note

Uses of TRIGGER include the following.

- Resume counting in the PMCs when PMC1 becomes negative, without causing a Performance Monitor interrupt. Then freeze all PMCs (and optionally cause a Performance Monitor interrupt) when a PMCj becomes negative. The PMCs then reflect the events that occurred between the time PMC1 became negative and the time a PMCj becomes negative. This use requires the following MMCR0 bit settings.
 - TRIGGER=1
 - PMC1CE=0
 - PMCjCE=1
 - TBEE=0
 - FCECE=1
 - PMAE=1 (if a Performance Monitor interrupt is desired)
- Resume counting in the PMCs when PMC1 becomes negative, and cause a Performance Monitor interrupt without freezing any PMCs. The PMCs then reflect the events that occurred between the time PMC1 became negative and the time the interrupt handler reads them. This use requires the following MMCR0 bit settings.
 - TRIGGER=1
 - PMC1CE=1
 - TBEE=0
 - FCECE=0
 - PMAE=1

51:52 Setting is implementation-dependent.

53:55 Reserved

56 **Performance Monitor Alert Occurred** (PMAO)

This bit is a basic feature.

- 0 A Performance Monitor alert has not occurred since the last time software set this bit to 0.
- 1 A Performance Monitor alert has occurred since the last time software set this bit to 0.

This bit is set to 1 by the hardware when a Performance Monitor alert occurs. This bit can be set to 0 only by the *mtspr* instruction.

Programming Note

Software can set this bit to 1 to simulate the occurrence of a Performance Monitor alert.

Software should set this bit to 0 after handling the Performance Monitor alert.

- 57 Setting is implementation-dependent.
- 58 **Freeze Counters 1-4 (FC1-4)**
- 0 PMC1 - PMC4 are incremented (if permitted by other MMCR bits).
- 1 PMC1 - PMC4 are not incremented.
- 59 **Freeze Counters 5-6 (FC5-6)**
- 0 PMC5 - PMC6 are incremented (if permitted by other MMCR bits).
- 1 PMC5 - PMC6 are not incremented.
- 60:61 Reserved
- 62 **Freeze Counters in Wait State (FCWAIT)**
- This bit is a basic feature.
- 0 The PMCs are incremented (if permitted by other MMCR bits).
- 1 The PMCs are not incremented if CTRL₃₁=0. Software is expected to set CTRL₃₁=0 when it is in a “wait state”, i.e., when there is no process ready to run.
- Only Branch Unit type of events do not increment if CTRL₃₁=0. Other units continue to count.
- 63 **Freeze Counters in Hypervisor State (FCH)**
- This bit is a basic feature.
- 0 The PMCs are incremented (if permitted by other MMCR bits).
- 1 The PMCs are not incremented if MSR_{HV PR}=0b10.

B.2.3 Monitor Mode Control Register 1

Monitor Mode Control Register 1 (MMCR1) is a 64-bit register. This register, along with MMCR0 and

MMCR1, controls the operation of the Performance Monitor.

Figure 59. Monitor Mode Control Register 1

MMCR1 is a basic feature. Within MMCR1, some of the bits and fields are basic features and some are extensions. The basic bits and fields are identified as such, below.

Some bits of MMCR1 are altered by the hardware when various events occur, as described below.

The bit definitions of MMCR1 are as follows. MMCR1 bits that are not implemented are treated as reserved.

Bit(s) Description

- 0:31 Implementation-Dependent Use
- These bits have implementation-dependent uses (e.g., extended event selection).
- 32:39 **PMC1 Selector** (PMC3SEL)
- 40:47 **PMC2 Selector** (PMC4SEL)
- 48:55 **PMC3 Selector** (PMC5SEL)
- 56:63 **PMC4 Selector** (PMC6SEL)

Each of these fields contains a code that identifies the event to be counted by PMCs 1 through 4 respectively.

PMC Selectors are basic features.

Compatibility Note

In versions of the architecture that precede Version 2.02 the PMC Selector Fields were six bits long, and were split between MMCR0 and MMCR1. PMC1-8 were all programmable.

If more programmable PMCs are implemented in the future, additional MMCRs may be defined to cover the additional selectors.

B.2.4 Monitor Mode Control Register A

Monitor Mode Control Register A (MMCR1) is a 64-bit register. This register, along with MMCR0 and MMCR1, controls the operation of the Performance Monitor.

Figure 60. Monitor Mode Control Register A

MMCR1 is a basic feature. Within MMCR1, some of the bits and fields are basic features and some are

extensions. The basic bits and fields are identified as such, below.

Some bits of MMCRA are altered by the hardware when various events occur, as described below.

The bit definitions of MMCRA are as follows. MMCRA bits that are not implemented are treated as reserved.

Bit(s)	Description
0:31	Reserved
32	Contents of SIAR and SDAR Are Related (CSSR) Set to 1 by the hardware if the contents of SIAR and SDAR are associated with the same instruction; otherwise set to 0.
33:34	Setting is implementation-dependent.
35	Sampled MSR_{HV} (SAMPHV) Value of MSR _{HV} when the Performance Monitor Alert occurred.
36	Sampled MSR_{PR} (SAMPPR) Value of MSR _{PR} when the Performance Monitor Alert occurred.
37:47	Setting is implementation-dependent.
48:53	Threshold (THRESHOLD) This field contains a “threshold value”, which is a value such that only events that exceed the value are counted. The events to which a threshold value can apply are implementation-dependent, as are the dimension of the threshold (e.g., duration in cycles) and the granularity with which the threshold value is interpreted.
<div style="border: 1px solid black; padding: 5px;"> <p style="text-align: center;">Programming Note</p> <p>By varying the threshold value, software can obtain a profile of the characteristics of the events subject to the threshold. For example, if PMC1 counts the number of cache misses for which the duration exceeds the threshold value, then software can obtain the distribution of cache miss durations for a given program by monitoring the program repeatedly using a different threshold value each time.</p> </div>	
54:59	Reserved for implementation-specific use.
60:62	Reserved
63	Setting is implementation-dependent.

B.2.5 Sampled Instruction Address Register

The Sampled Instruction Address Register (SIAR) is a 64-bit register. It contains the address of the “sampled instruction” when a Performance Monitor alert occurs.

Figure 61. Sampled Instruction Address Register

When a Performance Monitor alert occurs, SIAR is set to the effective address of an instruction that was being executed, possibly out-of-order, at or around the time that the Performance Monitor alert occurred. This instruction is called the “sampled instruction”.

The contents of SIAR may be altered by the hardware if and only if MMCR0_{PMAE}=1. Thus after the Performance Monitor alert occurs, the contents of SIAR are not altered by the hardware until software sets MMCR0_{PMAE} to 1. After software sets MMCR0_{PMAE} to 1, the contents of SIAR are undefined until the next Performance Monitor alert occurs.

See Section B.4 regarding the effects of the Trace facility on SIAR.

Programming Note

If the Performance Monitor alert causes a Performance Monitor interrupt, the value of MSR_{HV PR} that was in effect when the sampled instruction was being executed is reported in MMCRA.

B.2.6 Sampled Data Address Register

The Sampled Data Address Register (SDAR) is a 64-bit register. It contains the address of the “sampled data” when a Performance Monitor alert occurs.

Figure 62. Sampled Data Address Register

When a Performance Monitor alert occurs, SDAR is set to the effective address of the storage operand of an instruction that was being executed, possibly out-of-order, at or around the time that the Performance Monitor alert occurred. This storage operand is called the “sampled data”. The sampled data may be, but need not be, the storage operand (if any) of the sampled instruction (see Section B.2.5).

The contents of SDAR may be altered by the hardware if and only if MMCR0_{PMAE}=1. Thus after the Performance Monitor alert occurs, the contents of SDAR are not altered by the hardware until software sets

MMCR0_{PMAE} to 1. After software sets MMCR0_{PMAE} to 1, the contents of SDAR are undefined until the next Performance Monitor alert occurs.

See Section B.4 regarding the effects of the Trace facility on SDAR.

Programming Note

If the Performance Monitor alert causes a Performance Monitor interrupt, MMCRA indicates whether the sampled data is the storage operand of the sampled instruction.

B.3 Performance Monitor Interrupt

The Performance Monitor interrupt is a system caused interrupt (Section 6.4). It is masked by MSR_{EE} in the same manner that External and Decrementer interrupts are.

The Performance Monitor interrupt is a basic feature.

A Performance Monitor interrupt occurs when no higher priority exception exists, a Performance Monitor exception exists, and MSR_{EE}=1.

If multiple Performance Monitor exceptions occur before the first causes a Performance Monitor interrupt, the interrupt reflects the most recent Performance Monitor exception and the preceding Performance Monitor exceptions are lost.

The following registers are set:

SRR0 Set to the effective address of the instruction that would have been attempted to be executed next if no interrupt conditions were present.

SRR1

33:36 and 42:47

Implementation-specific.

Others Loaded from the MSR.

MSR See Figure 44 on page 828.

SIAR Set to the effective address of the “sampled instruction” (see Section B.2.5).

SDAR Set to the effective address of the “sampled data” (see Section B.2.6).

Execution resumes at effective address 0x0000_0000_0000_0F00.

In general, statements about External and Decrementer interrupts elsewhere in this Book apply also to the Performance Monitor interrupt; for example, if a Performance Monitor exception exists when an *mtm-srd[d]* instruction is executed that changes MSR_{EE} from 0 to 1, the Performance Monitor interrupt will

occur before the next instruction is executed (if no higher priority exception exists).

The priority of the Performance Monitor exception is equal to that of the External, Decrementer, and Hypervisor Decrementer exceptions (i.e., the hardware may generate any one of the four interrupts for which an exception exists) (see Section 6.7.2, “Ordered Exceptions” on page 845 and Section 6.8, “Interrupt Priorities” on page 845).

B.4 Interaction with the Trace Facility

If the Trace facility includes setting SIAR and SDAR (see Appendix C, “Example Trace Extensions” on page 879), and tracing is active (MSR_{SE}=1 or MSR_{BE}=1), the contents of SIAR and SDAR as used by the Performance Monitor facility are undefined and may change even when MMCR0_{PMAE}=0.

Programming Note

A potential combined use of the Trace and Performance Monitor facilities is to trace the control flow of a program and simultaneously count events for that program.

Appendix C. Example Trace Extensions

Note

This Appendix describes an example implementation of Trace Extensions. A subset of these requirements are being considered for inclusion in the Architecture as part of Category: Trace.

This appendix provides an example of extensions that may be added to the Trace facility described in Section 6.5.14, “Trace Interrupt [Category: Trace]” on page 839. It is only an example; implementations may provide all, some, or none of the features described here, or may provide features that are similar to those described here but differ in detail.

The extensions consist of the following features (described in detail below).

- use of $MSR_{SE\ BE}=0b11$ to specify new causes of Trace interrupts
- specification of how certain SRR1 bits are set when a Trace interrupt occurs
- setting of SIAR and SDAR (see Appendix B, “Example Performance Monitor” on page 869) when a Trace interrupt occurs

$MSR_{SE\ BE} = 0b11$

If $MSR_{SE\ BE}=0b11$, the hardware generates a Trace exception under the conditions described in Section 6.5.14 for $MSR_{SE\ BE}=0b01$, and also after successfully completing the execution of any instruction that would cause at least one of SRR1 bits 33:36, 42, and 44:46 to be set to 1 (see below) if the instruction were executed when $MSR_{SE\ BE}=0b10$.

This overrides the implicit statement in Section 6.5.14 that the effects of $MSR_{SE\ BE}=0b11$ are the same as those of $MSR_{SE\ BE}=0b10$.

SRR1

When a Trace interrupt occurs, the SRR1 bits that are not loaded from the MSR are set as follows instead of as described in Section 6.5.14.

- 33 Set to 1 if the traced instruction is *icbi*; otherwise set to 0.

- 34 Set to 1 if the traced instruction is *dcbt*, *dcbtst*, *dcbz*, *dcbst*, *dcbf[l]*; otherwise set to 0.
- 35 Set to 1 if the traced instruction is a Load instruction or *eciwx*; may be set to 1 if the traced instruction is *icbi*, *dcbt*, *dcbtst*, *dcbst*, *dcbf[l]*; otherwise set to 0.
- 36 Set to 1 if the traced instruction is a Store instruction, *dcbz*, or *ecowx*; otherwise set to 0.
- 42 Set to 1 if the traced instruction is *lswx* or *stswx*; otherwise set to 0.
- 43 Implementation-dependent.
- 44 Set to 1 if the traced instruction is a Branch instruction and the branch is taken; otherwise set to 0.
- 45 Set to 1 if the traced instruction is *eciwx* or *ecowx*; otherwise set to 0.
- 46 Set to 1 if the traced instruction is *lbarx*, *lharx*, *lwarx*, *ldarx*, *stbcx.*, *sthcx.*, *stwcx.*, or *stdcx.*; otherwise set to 0.
- 47 Implementation-dependent.

SIAR and SDAR

If the Performance Monitor facility is implemented and includes SIAR and SDAR (see Appendix B), the following additional registers are set when a Trace interrupt occurs:

- SIAR** Set to the effective address of the traced instruction.
- SDAR** Set to the effective address of the storage operand (if any) of the traced instruction; otherwise undefined.

If the state of the Performance Monitor is such that the Performance Monitor may be altering these registers (i.e., if $MMCR0_{PMAE}=1$), the contents of SIAR and SDAR as used by the Trace facility are undefined and may change even when no Trace interrupt occurs.

Appendix D. Interpretation of the DSISR as Set by an Alignment Interrupt

For most causes of Alignment interrupt, the interrupt handler will emulate the interrupting instruction. To do this, it needs the following characteristics of the interrupting instruction:

- Load or store
- Length (halfword, word, doubleword)
- String, multiple, or elementary
- Fixed-point or floating-point
- Update or non-update
- Byte reverse or not
- Is it *dcbz*?

The Power ISA optionally provides this information by setting bits in the DSISR that identify the interrupting instruction type. It is not necessary for the interrupt handler to load the interrupting instruction from storage. The mapping is unique except for a few exceptions that are discussed below. The near-uniqueness depends on the fact that many instructions, such as the fixed- and floating-point arithmetic instructions and the one-byte loads and stores, cannot cause an Alignment interrupt.

See Section 6.5.8 for a description of how the opcode and extended opcode are mapped to a DSISR value for an X-, D-, or DS-form instruction that causes an Alignment interrupt.

The table on the next page shows the inverse mapping: how the DSISR bits identify the interrupting instruction. The following notes are cited in the table.

1. For cases in which multiple instructions can give the same value for the DSISR bits (44:45 47:53) that are derived from the opcode, the Alignment interrupt handler should load the instruction from storage, using the effective address in SRR0, and treat the instruction appropriately (e.g., emulate the instruction, treat the case as a programming error, etc.). For example, if *lbarx* or *lwarx* causes an Alignment interrupt, it should not be emulated, but instead should be treated as a programming error.
2. These are distinguished by DSISR bits 44:45, which are not shown in the table.

The interrupt handler has no need to distinguish between an X-form instruction and the corresponding D- or DS-form instruction if one exists, and vice

versa. Therefore two such instructions may yield the same DSISR value (all 32 bits). For example, *stw* and *stwx* may both yield either the DSISR value shown in the following table for *stw*, or that shown for *stwx*.

If DSISR 47:53 is:	then it is either X- form opcode:	or D/ DS-form opcode:	so the instruction is:
00 0 0000	00000xxx00	x00000	lwarx, lwz, reserved(1)

Appendix E. Programming Examples

E.1 Unsigned Single-Precision-BCD Arithmetic

addg6s can be used to add or subtract two BCD operands. In these examples it is assumed that r0 contains 0x666...666. (BCD data formats are described in Section 5.3 of Book I.)

Addition of the unsigned BCD operand in register RA to the unsigned BCD operand in register RB can be accomplished as follows.

```
add    r1,RA,r0
add    r2,r1,RB
addg6s RT,r1,RB
subf   RT,RT,r2    # RT = RA +BCD RB
```

Subtraction of the unsigned BCD operand in register RA from the unsigned BCD operand in register RB can be accomplished as follows. (In this example it is assumed that RB is not register 0.)

```
addi   r1,RB,1
nor    r2,RA,RA    # one's complement of RA
add    r3,r1,r2
addg6s RT,r1,r2
subf   RT,RT,r3    # RT = RB -BCD RA
```

Additional instructions are needed to handle signed BCD operands, and BCD operands that occupy more than one register (e.g., unsigned BCD operands that have more than 16 decimal digits).

E.2 Signed Single-Precision BCD Arithmetic

Addition of the signed 15-digit BCD operand in register RA to the signed BCD operand in register RB can be accomplished as follows. If the signs of operands are different, then the operand of smaller magnitude is subtracted from the operand of larger magnitude and the sign of the larger operand is preserved; otherwise the operands are added and the sign is preserved.

The sign code is in the low order 4 bits of the operands and uses one of the standard encodings. (See Section 5.3 of Book I for a description of BCD and sign encodings.) This example assumes preferred sign option 1 (0b1100 is plus and 0b1101 is minus). For preferred sign option 2 (0b1111 is plus and 0b1101 is

minus), replace the **xori** after the "SignedSub" label with "**xori RA,RA,2**".

Preserving the appropriate sign code is accomplished by zeroing the sign code of the other operand before performing a 16 digit BCD addition/subtraction. Other addends (ones complement or 6's) must leave the sign code position as zero.

(In this example r11 contains 0x6666 6666 6666 6660.)

```
SignedSub:
xori   RA,RA,1

SignedAdd:
xor    r5,RA,RB
andi.  r5,r5,15    # compare sign codes
cmpld  cr1,RA,RB  # compare magnitudes
beq    cr0,samesign
ble    cr1,BminusA

# set up for RT = RA -BCD RB
nor    r9,RB,RB    # one's complement of RB
addi   r10,RA,16   # generate the carry in
b      submag

BminusA:
# set up for RT = RB -BCD RA
nor    r9,RA,RA    # one's complement of RA
addi   r10,RB,16   # generate the carry in

submag:
rldicr r9,r9,0,59  # remove the sign code
add    r8,r10,r9
addg6s RT,r10,r9
rldicr RT,RT,0,59  # remove generated 6 from
# sign position

subf   RT,RT,r8
b      done

samesign:
rldicr r8,RB,0,59  # remove the sign code
add    r10,RA,r11  # add 6's
add    r9,r10,r8
addg6s RT,r10,RB
subf   RT,RT,r9    # RT = RA +BCD RB

done:
```

E.3 Unsigned Extended-Precision BCD Arithmetic

Multiple precision BCD arithmetic requires additional code to add/subtract higher order digits and handle the carry between 16 digit groups. For example, the following sequence implements a 32-digit BCD add. In this example the contents of register R3 concatenated with the contents of R4 represent the first 32-digit operand and the contents of register R5 concatenated with the contents of R6 represents the second operand. The contents of register R3 concatenated with the contents of register R4 represents the result.

(In this example r0 contains 0x6666 6666 6666 6666.)

```
add     r10,R4,r0
addc    r9,r10,R6    # generate the carry
addg6s  R4,r10,R6
subf    R4,R4,r9     # RT1 = RA1 +BCD RB1

addze   R5,R5       # propagate the carry
add     r10,R3,r0
add     r9,r10,R5
addg6s  R3,r10,R5
subf    R3,R3,r9     # RT0 = RA0 +BCD RB0
```

Note that an extra instruction (**addze**) is required to propagate the carry so that the same value is used in the subsequent **add** and **addg6s**.

The following sequence implements a 32-digit BCD subtraction. In this example the first operand in R3 and R4 is subtracted from the 2nd operand in R5 and R6. The result is in R3 and R4.

```
addi    r10,R6,1
nor     r9,R4,R4     # one's complement of RA0
addc    r8,r10,r9    # Generate the carry
addg6s  R4,r10,r9
subf    R4,R4,r8     # RT1 = RB1 -BCD RA1

addze   r10,R5       # propagate the carry
nor     r9,R3,R3     # one's complement of RA0
add     r8,r10,r2
addg6s  R3,r10,r9
subf    R3,R3,r8     # RT0 = RB0 -BCD RA0
```

Book III-E:

**Power ISA Operating Environment Architecture - Embedded
| Environment [Category: Embedded]**

Chapter 1. Introduction

1.1 Overview	889	1.5 Exceptions	892
1.2 32-Bit Implementations	889	1.6 Synchronization	892
1.3 Document Conventions	889	1.6.1 Context Synchronization	892
1.3.1 Definitions and Notation	889	1.6.2 Execution Synchronization	893
1.3.2 Reserved Fields	891		
1.4 General Systems Overview	891		

1.1 Overview

Chapter 1 of Book I describes computation modes, document conventions, a general systems overview, instruction formats, and storage addressing. This chapter augments that description as necessary for the Power ISA Operating Environment Architecture.

1.2 32-Bit Implementations

Though the specifications in this document assume a 64-bit implementation, 32-bit implementations are permitted as described in Appendix C, “Guidelines for 64-bit Implementations in 32-bit Mode and 32-bit Implementations” on page 1111.

1.3 Document Conventions

The notation and terminology used in Book I apply to this Book also, with the following substitutions.

- For “system alignment error handler” substitute “Alignment interrupt”.
- For “system auxiliary processor enabled exception error handler” substitute “Auxiliary Processor Enabled Exception type Program interrupt”,
- For “system data storage error handler” substitute “Data Storage interrupt” or “Data TLB Error interrupt” as appropriate.
- For “system error handler” substitute “interrupt”.
- For “system floating-point enabled exception error handler” substitute “Floating-Point Enabled Exception type Program interrupt”.
- For “system illegal instruction error handler” substitute “Illegal Instruction exception type Program

interrupt” or “Unimplemented Operation exception type Program interrupt”, as appropriate.

- For “system instruction storage error handler” substitute “Instruction Storage interrupt” or “Instruction TLB Error”, as appropriate.
- For “system privileged instruction error handler” substitute “Privileged Instruction exception type Program interrupt”.
- For “system service program” substitute “System Call interrupt”.
- For “system trap handler” substitute “Trap type Program interrupt”.

1.3.1 Definitions and Notation

The definitions and notation given in Books I and II are augmented by the following.

- Threaded processor, single-threaded processor, thread

A threaded processor implements one or more “threads”, where a thread corresponds to the Book I/II concept of “processor”. That is, the definition of “thread” is the same as the Book I definition of “processor”, and “processor” as used in Books I and II can be thought of as either a single-threaded processor or as one thread of a multi-threaded processor. The only unqualified uses of “processor” in Book III are in resource names (e.g. Processor Identification Register); such uses should be regarded as meaning “threaded processor”. The threads of a multi-threaded processor typically share certain resources, such as the hardware components that execute certain kinds of instructions (e.g., Fixed-Point instructions), certain

caches, the address translation mechanism, and certain hypervisor resources.

- Thread enabled, thread disabled

A thread can be enabled or disabled. When enabled, the thread can prefetch and execute instructions; when disabled, prefetched instructions are discarded, and the thread cannot prefetch or execute instructions.

- Performed

An explicit modification, by a thread T1, of a shared SPR (using *mtspr*) or an entry in a shared TLB (using *tlbwe*), is performed with respect to thread T2 when a read of the shared SPR or TLB entry (using *mfspr* or *tlbre* respectively) by T2 will return the result of the modification (or of a subsequent modification). For T2, the effects of such a modification having been performed with respect to T2 are the same as if the *mtspr* or *tlbwe* were in T2's instruction stream at the point at which the modification was performed with respect to T2. T1 and T2 may be any threads that share the SPR or TLB with one another, and may be the same thread.

- real page

A unit of real storage that is aligned at a boundary that is a multiple of its size. The real page size may range from 1KB to 1TB [MAV=1.0] or to 2TB [MAV=2.0].

- [MAV=x.x]

Instructions and facilities are considered part of all MMU architecture versions unless otherwise marked. If a facility or section is marked with a specific MMU Architecture version x.x, that facility or all material in that section and its subsections are considered part of the specific MMU architecture version.

- "must"

If the Embedded.Hypervisor category is not supported and privileged software violates a rule that is stated using the word "must", the results are undefined. If the Embedded.Hypervisor category is supported, the following applies.

- If hypervisor software violates a rule that is stated using the word "must" (e.g., "this field must be set to 0"), and the rule pertains to the contents of a hypervisor resource, to executing an instruction that can be executed only in hypervisor state, or to accessing storage using a TLB entry with a TGS value of 0, the results are undefined, and may include altering resources belonging to other partitions, causing the system to "hang", etc.
- If supervisor software violates the requirements for storage control bit values or their

alteration, the result of accessing the associated storage is undefined.

- In other cases of violation of a rule that is stated using the word "must", the results are boundedly undefined unless otherwise stated.

Programming Note

Contrary to the general principle of partition isolation, the result of accessing storage associated with violations of the requirements for storage control bit values and their alteration is specified as "undefined". This is the only case where a guest operating system can cause "undefined" results. Embedded architecture does this as a hardware simplification because of the limited amount of code involved with storage control bits and because operating systems used in the Embedded environment can be tested and then controlled.

- context of a program

The state (e.g., privilege and relocation) in which the program executes. The context is controlled by the contents of certain System Registers, such as the MSR, of certain lookaside buffers, such as the TLB, and of other resources.

- exception

An error, unusual condition, or external signal, that may set a status bit and may or may not cause an interrupt, depending upon whether the corresponding interrupt is enabled.

- interrupt

The act of changing the machine state in response to an exception, as described in Chapter 7. "Interrupts and Exceptions" on page 1013.

- trap interrupt

An interrupt that results from execution of a *Trap* instruction.

- Additional exceptions to the sequential execution model, beyond those described in the section entitled "Instruction Fetching" in Book I, are the following.

- A reset or Machine Check interrupt may occur. The determination of whether an instruction is required by the sequential execution model is not affected by the potential occurrence of a reset or Machine Check interrupt. (The determination is affected by the potential occurrence of any other kind of interrupt.)
- A context-altering instruction is executed (Chapter 12. "Synchronization Requirements

for Context Alterations” on page 1099). The context alteration need not take effect until the required subsequent synchronizing operation has occurred.

- hardware

Any combination of hard-wired implementation, emulation assist, or interrupt for software assistance. In the last case, the interrupt may be to an architected location or to an implementation-dependent location. Any use of emulation assists or interrupts to implement the architecture is implementation-dependent.

- hypervisor privileged (or hypervisor-privileged)

If category E.HV is implemented, this term describes an instruction, register, or facility that is available only when the thread is in hypervisor state. Otherwise, this term describes an instruction, register, or facility that is available only when the thread is in supervisor state.

- privileged state and supervisor state

Used interchangeably to refer to a state in which privileged facilities are available.

- guest state

A state used to run software under control of a hypervisor program in which hypervisor-privileged facilities are not available.

- guest supervisor state

A state which is in both the guest state and the supervisor state.

- problem state and user mode

Used interchangeably to refer to a state in which privileged facilities are not available.

- directed

In a hypervised system, the attribute of an interrupt that execution occurs in the guest supervisor or hypervisor state as described in Section 2.3.1, “Directed Interrupts”.

- /, //, ///, ... denotes a field that is reserved in an instruction, in a register, or in an architected storage table.

- ?, ??, ???, ... denotes a field that is implementation-dependent in an instruction, in a register, or in an architected storage table.

1.3.2 Reserved Fields

Some fields of certain architected registers may be written to automatically by the hardware, e.g., Reserved bits in System Registers. When the hardware writes to such a register, the following rules are obeyed.

- Unless otherwise stated, no defined field other than the one(s) specifically being updated are modified.

- Contents of reserved fields are either preserved or written as zero.

The reader should be aware that reading and writing of some of these registers (e.g., the MSR) can occur as a side effect of processing an interrupt and of returning from an interrupt, as well as when requested explicitly by the appropriate instruction (e.g., *mtmsr* instruction).

1.4 General Systems Overview

The hardware contains the sequencing and processing controls for instruction fetch, instruction execution, and interrupt action. Most implementations also contain data and instruction caches. Instructions fall into the following classes:

- instructions executed in the Branch Facility
- instructions executed in the Fixed-Point Facility
- instructions executed in the Floating-Point Facility
- instructions executed in the Vector Facility
- instructions executed in an Auxiliary Processor
- other instructions

Almost all instructions executed in the Branch Facility, Fixed-Point Facility, Floating-Point Facility, and Vector Facility are nonprivileged and are described in Book I. Book I may describe additional nonprivileged instructions (e.g., Book II describes some nonprivileged instructions for cache management). Instructions executed in an Auxiliary Processor are implementation-dependent. Instructions related to the supervisor mode, control of hardware resources, control of the storage hierarchy, and all other privileged instructions are described here or are implementation-dependent.

1.5 Exceptions

The following augments the exceptions defined in Book I that can be caused directly by the execution of an instruction:

- the execution of a floating-point instruction when $MSR_{FP}=0$ (Floating-Point Unavailable interrupt)
- execution of an instruction that causes a debug event (Debug interrupt).
- the execution of an auxiliary processor instruction when the auxiliary processor is unavailable (Auxiliary Processor Unavailable interrupt)
- the execution of a Vector, SPE, or Embedded Floating-Point instruction when $MSR_{SPV}=0$ (SPE/Embedded Floating-Point/Vector Unavailable interrupt)

1.6 Synchronization

The synchronization described in this section refers to the state of the thread that is performing the synchronization.

1.6.1 Context Synchronization

An instruction or event is *context synchronizing* if it satisfies the requirements listed below. Such instructions and events are collectively called *context synchronizing operations*. The context synchronizing operations include the *dnh* instruction, the *isync* instruction, the *System Linkage* instructions, the *mtmsr* instruction, and most interrupts (see Section 7.1). Also, the combination of disabling and enabling a thread is context-synchronizing for the thread being enabled (See Section 3).

1. The operation causes instruction dispatching (the issuance of instructions by the instruction fetching mechanism to any instruction execution mechanism) to be halted.
2. The operation is not initiated or, in the case of *dnh* [Category: Embedded.Enhanced Debug], *isync* does not complete, until all instructions that precede the operation have completed to a point at which they have reported all exceptions they will cause.
3. The operation ensures that the instructions that precede the operation will complete execution in the context (privilege, relocation, storage protection, etc.) in which they were initiated.
4. If the operation directly causes an interrupt (e.g., *sc* directly causes a System Call interrupt) or is an interrupt, the operation is not initiated until no exception exists having higher priority than the exception associated with the interrupt (see Section 7.9, "Exception Priorities" on page 1059).
5. The operation ensures that the instructions that follow the operation will be fetched and executed in the context established by the operation. (This requirement dictates that any prefetched instructions be discarded and that any effects and side effects of executing them out-of-order also be discarded, except as described in Section 6.5, "Performing Operations Out-of-Order".)

The operation ensures that all explicit modifications of shared SPRs (*mtspr*) and shared TLBs (*tlbwe*), caused by instructions that precede the operation, have been performed with respect to all other threads that share the SPR or TLB.

Programming Note

The context established by a context synchronizing operation includes modifications to shared resources by other threads, that were performed with respect to the context synchronizing thread before the operation was initiated. Examples of potentially shared resources include TLBs and SPRs such as the LPIDR.

Programming Note

A context synchronizing operation is necessarily execution synchronizing; see Section 1.6.2.

Unlike the *Synchronize* instruction, a context synchronizing operation does not affect the order in which storage accesses are performed.

Item 2 permits a choice only for *isync* (and *sync*; see Section 1.6.2) because all other execution synchronizing operations also alter context.

1.6.2 Execution Synchronization

An instruction is *execution synchronizing* if it satisfies items 2 and 3 of the definition of context synchronization (see Section 1.6.1). *sync* is treated like *isync* with respect to item 2. The execution synchronizing instructions are *sync*, *mtmsr* and all context synchronizing instructions.

Programming Note

Unlike a context synchronizing operation, an execution synchronizing instruction does not ensure that the instructions following that instruction will execute in the context established by that instruction. This new context becomes effective sometime after the execution synchronizing instruction completes and before or at a subsequent context synchronizing operation.

Chapter 2. Logical Partitioning [Category: Embedded.Hypervisor]

2.1 Overview	895	2.3 Interrupts and Exceptions	896
2.2 Registers	896	2.3.1 Directed Interrupts	896
2.2.1 Register Mapping	896	2.3.2 Hypervisor Service Interrupts	897
2.2.2 Logical Partition Identification Register (LPIDR)	896	2.4 Instruction Mapping	897

2.1 Overview

The Embedded.Hypervisor category permits threads and portions of real storage to be assigned to logical collections called *partitions*, such that a program executing in one partition cannot interfere with any program executing in a different partition. This isolation can be provided for both problem state and privileged state programs, by using a layer of trusted software, called a *hypervisor* program (or simply a “hypervisor”), and the resources provided by this facility to manage system resources. The collection of software that runs in a given partition and its associated resources is called a *guest*. The guest normally includes an operating system (or other system software) running in privileged state and its associated processes running in the problem state under the management of the hypervisor. The thread is in the *guest state* when a guest is executing and is in the *hypervisor state* when the hypervisor is executing. The thread is executing in the guest state when $MSR_{GS\ PR}=1$.

The number of partitions supported is implementation-dependent.

A thread is assigned to one partition at any given time. A thread can be assigned to any given partition without consideration of the physical configuration of the system (e.g. shared registers, caches, organization of the storage hierarchy), except that threads that share certain hypervisor resources may need to be assigned to the same partition. Additionally, certain resources may be utilized by the guest at the discretion of the hypervisor. Such usage may cause interference between partitions and the hypervisor should allocate those resources accordingly. The primary registers and facilities used to control Logical Partitioning are listed below and described in the following subsections. Other facili-

ties associated with Logical Partitioning are described within the appropriate sections within this Book.

An instruction that is *hypervisor privileged* must be execute in the hypervisor state ($MSR_{GS\ PR} = 0b00$). If an attempt is made to execute a hypervisor-privileged instruction in the guest supervisor state ($MSR_{GS\ PR} = 0b10$), an Embedded Hypervisor Privilege exception occurs. A register that is *hypervisor privileged* may only be accessed in the hypervisor state ($MSR_{GS\ PR} = 0b00$). If a hypervisor-privileged register is accessed in the guest supervisor state ($MSR_{GS\ PR} = 0b10$), an Embedded Hypervisor Privilege exception occurs.

When $MSR_{GS\ PR} = 0b01$ or $MSR_{GS\ PR} = 0b11$, the thread is in problem (user) state. The resources (instructions and registers) that are available are generally the same when $MSR_{PR} = 0b1$ regardless of the state of MSR_{GS} , however when $MSR_{GS\ PR} = 0b11$ some interrupts are directed to the guest supervisor state. When $MSR_{GS\ PR} = 0b01$ interrupts are always directed to the hypervisor (see Section 2.3.1, “Directed Interrupts”).

Category Embedded.Hypervisor changes the operating system programming model to allow for easier virtualization, while retaining a default backward compatible mode in which an operating system written for hardware not implementing this category will still operate as before without using the Logical Partitioning facilities.

Category Embedded.Hypervisor requires that category Embedded.Processor Control and category Embedded.MMU Type FSL are also supported.

2.2 Registers

Registers specific to Logical Partitioning and hypervisor control are defined in this section. Other registers which are hypervisor privileged or have hypervisor-only fields appear and are described in other sections in this Book.

2.2.1 Register Mapping

To facilitate better performance for operating systems executing in the guest supervisor state, some Special Purpose Register (SPR) accesses are redirected to analogous guest-state SPRs. An SPR is said to be *mapped* if this redirection takes place when executing in guest supervisor state. These guest-state SPRs separate performance critical state of the hypervisor and the operating system executing in guest supervisor state. The mapping of these register accesses allows the same programming model to be used for an operating system running in the guest supervisor state or in the hypervisor state.

For example, when a *mtspr* SRR0,r5 instruction is executed in guest supervisor state, the access to SRR0 is mapped to GSRR0. This produces the same operation as executing *mtspr* GSRR0,r5

Programming Note

Since accesses to the mapped SPRs are automatically mapped to the appropriate guest-accessible SPR, guest supervisor software should use the original SPRs for accessing these registers (i.e. SRR0, not GSRR0). This facilitates using the same code in hypervisor or guest state.

SPR accesses that are mapped in guest supervisor state are listed in Table 1.

SPR Accessed	SPR Mapped to	Type of Access
SRR0	GSRR0	<i>mtspr, mfspr</i>
SRR1	GSRR1	<i>mtspr, mfspr</i>
EPR	GEPR	<i>mfspr</i>
ESR	GESR	<i>mtspr, mfspr</i>
DEAR	GDEAR	<i>mtspr, mfspr</i>
PIR	GPIR	<i>mfspr</i>
SPRG0	GSPRG0	<i>mtspr, mfspr</i>
SPRG1	GSPRG1	<i>mtspr, mfspr</i>
SPRG2	GSPRG2	<i>mtspr, mfspr</i>

¹ If an implementation permits user access to SPRG3, user access to GSPRG3 should also be permitted. In this case, the access is mapped when executing in guest state regardless of the setting of MSR_{PR}

Table 1: Mapped SPRs

SPR Accessed	SPR Mapped to	Type of Access
SPRG3	GSPRG3	<i>mtspr, mfspr</i>

¹ If an implementation permits user access to SPRG3, user access to GSPRG3 should also be permitted. In this case, the access is mapped when executing in guest state regardless of the setting of MSR_{PR}

Table 1: Mapped SPRs

2.2.2 Logical Partition Identification Register (LPIDR)

The Logical Partition Identification Register (LPIDR) contains the Logical Partition ID (LPID) currently in use for the thread. The format of the LPIDR is shown in Figure 1 below.

Figure 1. Logical Partition Identification Register

The LPIDR is part of the virtual address. During address translation, its content is compared to the TLPID field in the TLB entry to determine a matching TLB entry.

The LPIDR is hypervisor privileged.

The 12 least significant bits of LPIDR contain the LPID value. All 12 bits do not need to be implemented. Unimplemented bits should read as zero. The number of implemented bits is reported in MMUCFG_{LPIDSIZE}

2.3 Interrupts and Exceptions

2.3.1 Directed Interrupts

Category Embedded. Hypervisor introduces new interrupt semantics. Interrupts are *directed* to either the guest state or the hypervisor state. The state to which interrupts are directed determines which SPRs are used to form the vector address, which save/restore registers are used to capture the thread state at the time of the interrupt, and which registers are used to post exception status.

- If IVORs [Category: Embedded.Phased-Out] are supported, interrupts directed to the guest state use the Guest Interrupt Vector Prefix Register (GIVPR) to determine the high-order 48 bits of the vector address and use Guest Interrupt Vector Registers (GIVORs) to provide the low-order 16 bits (of which the last 4 bits are 0).
- If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, interrupts directed to the guest state use the Guest Interrupt Vector Prefix Register (GIVPR) to determine the high-

order 52 bits of the vector address and use the 12-bit exception vector offsets (described in Section 7.2.15) to provide the low-order 12 bits (of which the last 5 bits are 0).

- If IVORs [Category: Embedded.Phased-Out] are supported, interrupts directed to the embedded hypervisor state use the IVPR for the upper 48 bits of the address and the IVORs for the lower 16 bits of the address.
- If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, interrupts directed to the embedded hypervisor state use one of the following for the interrupt vector address.
 - If the Machine Check Interrupt Vector Prefix Register (see Section 7.2.18.4) is supported and the interrupt is a Machine Check, MCIVPR provides the high-order 52 bits of the vector address and the 12-bit exception vector offsets (described in Section 7.2.15) provides the low-order 12 bits (of which the last 5 bits are 0).
 - Otherwise, IVPR provides the high-order 52 bits of the vector address and the 12-bit exception vector offsets (described in Section 7.2.15) provides the low-order 12 bits (of which the last 5 bits are 0).

Interrupts that are directed to the guest state use GSRR0/GSRR1 registers to save the context at interrupt time. Interrupts directed to the embedded hypervisor state use SRR0/SRR1, with the exception of Guest Processor Doorbell interrupts which use GSRR0/GSRR1.

Most interrupts are directed to the hypervisor state. Some interrupts may be directed to the guest state if the thread is currently executing in guest state ($MSR_{GS} = 1$) and the interrupt is configured by the EPCR to the guest state or the interrupt is a System Call Interrupt. An Instruction Storage or Data Storage interrupt resulting from a TLB Ineligible exception <E.PT> is always directed to the hypervisor state. Debug interrupts, Critical interrupts, and Machine Check interrupts are always directed to the hypervisor state.

2.3.2 Hypervisor Service Interrupts

Two interrupts exist as mechanisms for the hypervisor to provide services to the guest.

The Embedded Hypervisor Privilege Interrupt occurs when guest supervisor state attempts execution of a hypervisor-privileged instruction or attempts to access a hypervisor-privileged resource. This can be used by the hypervisor to provide virtualization services for the guest. The Embedded Hypervisor Privilege Interrupt is described in Section 7.6.28, “Embedded Hypervisor Privilege Interrupt [Category: Embedded.Hypervisor]”. An Embedded Hypervisor Privilege Interrupt will also

occur if a *ehpriv* instruction is executed regardless of the thread state.

The Embedded Hypervisor System Call Interrupt occurs when an *sc* instruction is executed and $LEV=1$. The *sc* instruction is described in Section 4.3.1, “System Linkage Instructions”.

2.4 Instruction Mapping

When executing in the guest supervisor state ($MSR_{GS} = 0b10$), execution of an *rfi* instruction is mapped to *rfgi* and the *rfgi* instruction is executed in place of the *rfi*. The mapping of these instructions allows the same programming model to be used for an operating system running in the guest supervisor state or in the hypervisor state.

Chapter 3. Thread Control [Category: Embedded Multi-Threading]

3.1 Overview	899	3.7 Thread Management Facility [Category: Embedded Multithreading.Thread Management].	901
3.2 Thread Identification Register (TIR)	899	3.7.1 Initialize Next Instruction Address Registers	901
3.3 Thread Enable Register (TEN)	899	3.7.2 Thread Management Instructions	902
3.4 Thread Enable Status Register (TENSr)	900		
3.5 Disabling and Enabling Threads	900		
3.6 Sharing of Multi-Threaded Processor Resources	900		

3.1 Overview

The Thread Control facility permits the hypervisor to control and monitor the execution, priority, and other aspects of threads.

3.2 Thread Identification Register (TIR)

The layout of the TIR is shown in below.

Figure 2. Thread Identification Register

The TIR is a 64-bit read-only register that can be used to distinguish the thread from other threads on a multi-threaded processor. Threads are numbered sequentially, with valid values ranging from 0 to $t-1$, where t is the number of threads implemented. A thread for which $TIR = n$ is referred to as “thread n .”

The TIR is hypervisor privileged.

3.3 Thread Enable Register (TEN)

The layout of the TEN is shown in below.

Figure 3. Thread Enable Register

The TEN is a 64-bit register. For $t < T$, where T is the number of threads supported by the implementation, bit $63-t$ corresponds to thread t . When TEN_{63-t} is 0, thread t is disabled. When TEN_{63-t} is 1, thread t is enabled.

Software is permitted to write any value to bits 0:63-T; a subsequent reading of these bits always returns 0.

The TEN can be accessed using two SPR numbers.

- When SPR 438 (Thread Enable Set, or TENS) is written, threads for which the corresponding bit in TENS is 1 are enabled; threads for which the corresponding bit in TENS is 0 are unaffected.
- When SPR 439 (Thread Enable Clear, or TENC) is written, threads for which the corresponding bit in TENC is 1 are disabled; threads for which the corresponding bit in TENC is 0 are unaffected.

When each SPR is read, the current value of the TEN is returned.

The TEN is hypervisor privileged.

Programming Note

Software can determine the number of threads supported by the implementation by setting each progressively higher-order bit to 1, and testing whether a subsequent read returns a 1. Because this operation enables the thread, software should ensure that an acceptable instruction sequence is located at the thread's starting effective address. (See Section 8.3, "Thread State after Reset".)

3.4 Thread Enable Status Register (TENSr)

The layout of the TENSr is shown in below.

Figure 4. Thread Enable Status Register

The TENSr is a 64-bit read-only register. Bit 63-t of the TENSr corresponds to thread t. The contents of the TENSr are equal to the contents of the TEN, except that when TEN_{63-t} changes from 1 to 0, $TENSr_{63-t}$ does not change from 1 to 0 until thread t is disabled.

The TENSr is hypervisor privileged.

3.5 Disabling and Enabling Threads

The combination of disabling and enabling a thread is context-synchronizing for the thread being enabled. Steps 1-3 of context synchronization (see Section 1.6.1) occur as a result of the thread being disabled, and updates to SPRs and shared TLBs caused by preceding instructions executed by the thread occur. When all updates to these shared SPRs and shared TLBs have been performed with respect to all other threads on a multi-threaded processor, the TENSr bit corresponding to the disabled thread is set to 0.

Asynchronous interrupts that occur after the thread is disabled are pended until the thread is enabled.

When a thread is enabled by setting the TEN bit corresponding to the thread to 1, the thread begins execution at the next instruction to be executed when it was disabled or at the effective address specified by the INIA [Category: Embedded Multi-threading.Thread Management] if the INIA corresponding to the thread was written while the thread was disabled.

Programming Note

The architecture provides no method to make a thread's updates to shared storage visible to other threads before it is disabled. Similarly, the architecture provides no method to make updates to shared storage made while a thread is disabled visible to a thread when it is subsequently enabled.

Programming Note

When thread T1 disables other threads, Tn, it sets the TEN bits corresponding to Tn to 0s. In order to ensure that all updates to shared SPRs and shared TLBs caused by instructions being performed by threads Tn have been performed with respect to all threads on a multi-threaded processor, thread T1 reads the TENSr until all the bits corresponding to the disabled threads, Tn, are 0s.

3.6 Sharing of Multi-Threaded Processor Resources

The PVR and TEN must be shared among all threads of a multi-threaded processor. Various other resources are allowed to be shared among threads. Programs that modify shared resources must be aware of such sharing, and must allow for the fact that changes to these resources may affect more than one thread.

Resources that may be shared are grouped into the following five groups of related resources. If any of the resources in a group are shared among threads, all of the resources in the group must be shared.

- ATB, ATBL, ATBU [Category: ATB]
- IVORs [Category: Phased-Out]
- IVPR
- TB, TBL, TBU
- MMUCFG, MMUCSR0, TLB, TLBnCFG, TLBnCFG2, TLBnEPT, [Category: Embedded.Hypervisor.LRAT]: LRAT, LRATCFG, LRATCFG2

If the implementation requires all threads to be in the same partition, the following additional groups of resources may be shared. If any of the resources in a group are shared among threads, all of the resources in the group must be shared.

- DAC1, DAC2, DVC1, DVC2, IAC1, IAC2, IAC3
- EHCSR [Category: Embedded.Hypervisor]
- GIVORs [Category: Phased-Out]
- GIVPR [Category: Embedded.Hypervisor]
- LPIDR [Category: Embedded.Hypervisor]

Certain implementation-dependent registers, instruction and Data Caches, and implementation-dependent look-aside information may also be shared.

The set of resources that are shared is implementation-dependent.

Programming Note

When software executing in thread T1 writes a new value in an SPR (*mtspr*) that is shared with other threads, or explicitly writes to an entry in a shared TLB (*tlbwe*), either of the following sequences of operations can be performed in order to ensure that the write operation has been performed with respect to other threads.

Sequence 1

- Disable all other threads (see Section 3.5)
- Write to the shared SPR (*mtspr*) or to the shared TLB (*tlbwe*)
- Perform a context synchronizing operation
- Enable the previously-disabled threads

In the above sequence, the context synchronizing operation ensures that the write operation has been performed with respect to all other threads that share the SPR or TLB; the enabling of other threads ensures that subsequent instructions of the enabled threads use the new SPR or TLB value since enabling a thread is a context synchronizing operation.

Sequence 2

- All threads are put in hypervisor state and begin polling a storage flag
- The thread updating the SPR or TLB does the following:
 - Writes to the SPR (*mtspr*) or the TLB (*tlbwe*)
 - Sets a storage flag indicating the write operation was done
 - Performs a context synchronizing operation
- When other threads see the updated storage flag, they perform context synchronizing operations.

In the above sequence, the context synchronizing operation by the thread that writes to the SPR or TLB ensures that the write operation has been performed with respect to all other threads that share the SPR or TLB; the context synchronizing operation by the other threads ensure that subsequent instructions for these threads use the updated value.

3.7 Thread Management Facility

[Category: Embedded Multi-threading.Thread Management]

The thread management facility enables software to control features related to threads. The capabilities provided allow software, for a disabled thread, to specify the address of the instruction to be executed when the thread is enabled. Other implementation-dependent capabilities may also be provided.

3.7.1 Initialize Next Instruction Address Registers

The Initialize Next Instruction Address (INIA_n, where $n = 0..63$) registers are 64-bit write-only registers that can be used to specify the effective address of the instruction to be executed when a currently-disabled thread is enabled. INIA_n corresponds to thread n .

Figure 5. Initialize Next Instruction Address Register

Bit 63 is always 0. Bit 62 is part of the Instruction Address if Category: VLE is supported; otherwise bit 62 is always 0.

When the INIA is written in 32-bit mode, bits 0:31 are set to 0s.

The initial value of all INIAs is x'FFFF FFFF FFFF FFFC.'

3.7.2 Thread Management Instructions

Move To Thread Management Register *XFX-form*

mttmr TMR,RS

31	RS	tmr	494	/
0	6	11	21	31

$n \leftarrow \text{tmr}_{5:9} \parallel \text{tmr}_{0:4}$
 $\text{TMR}(n) \leftarrow (\text{RS})$

The TMR field denotes a Thread Management Register, encoded as shown in the table below. The contents of register RS are placed into the designated Thread Management Register.

decimal	TMR [†]		Register Name
	tmr _{5:9}	tmr _{0:4}	
320	01010	00000	INIA ₀
...
383	10111	11111	INIA ₆₃

[†] Note that the order of the two 5-bit halves of the SPR number is reversed.

Figure 6. Thread Management Register Numbers

All values of the TMR field not shown in Figure 6 are implementation-specific.

An implementation only provides INIA registers corresponding to its implemented threads. Execution of this instruction specifying a TMR number that is not defined for the implementation causes an Illegal Instruction type Program interrupt if MSR_{GS PR}=0b00.

This instruction is hypervisor privileged.

Special Registers Altered:

See above

Chapter 4. Branch Facility

4.1 Branch Facility Overview	903	4.2.3 Embedded Processor Control Register (EPCR)	906
4.2 Branch Facility Registers	903	4.3 Branch Facility Instructions	908
4.2.1 Machine State Register	903	4.3.1 System Linkage Instructions	908
4.2.2 Machine State Register Protect Register (MSRP)	905		

4.1 Branch Facility Overview

This chapter describes the details concerning the registers and the privileged instructions implemented in the Branch Facility that are not covered in Book I.

4.2 Branch Facility Registers

4.2.1 Machine State Register

The MSR (MSR) is a 32-bit register. MSR bits are numbered 32 (most-significant bit) to 63 (least-significant bit). This register defines the state of the thread. The MSR can also be modified by the *mtmsr*, *rfi*, *rfci*, *rfdi* [Category: Embedded.Enhanced Debug], *rfmci*, *rfgi* [Category: Embedded.Hypervisor], *wrtee* and *wrteei* instructions and interrupts. It can be read by the *mfmsr* instruction.

Figure 7. Machine State Register

Below are shown the bit definitions for the Machine State Register.

Bit	Description
32	Computation Mode (CM) 0 The thread runs in 32-bit mode. 1 The thread runs in 64-bit mode.
33	Reserved
34	Implementation-dependent
35	Guest State (GS) [Category: Embedded.Hypervisor]

- 0 The thread is in hypervisor state if MSR_{PR} = 0.
- 1 The thread is in guest state.

MSR_{GS} cannot be changed unless thread is in the hypervisor state.

36 Implementation-dependent

37 **User Cache Locking Enable (UCLE)**
[Category: Embedded Cache Locking.User Mode]

- 0 *Cache Locking* instructions are privileged.
- 1 *Cache Locking* instructions can be executed in user mode (MSR_{PR}=1).

If category Embedded Cache Locking.User Mode is not supported, this bit is treated as reserved.

38 **SP/Embedded Floating-Point/Vector Available (SPV)**

[Category: Signal Processing]:

- 0 The thread cannot execute any SP instructions except for the *brinc* instruction.
- 1 The thread can execute all SP instructions.

[Category: Vector]:

- 0 The thread cannot execute any Vector instruction.
- 1 The thread can execute Vector instructions.

39:45 Reserved

46	Critical Enable (CE)		
	0 Critical Input, Watchdog Timer, Guest Processor Doorbell Critical <E.HV>, and Processor Doorbell Critical interrupts are disabled.	51	Machine Check Enable (ME)
	1 Critical Input, Watchdog Timer, Guest Processor Doorbell Critical <E.HV>, and Processor Doorbell Critical interrupts are enabled.		0 Machine Check interrupts are disabled.
			1 Machine Check interrupts are enabled.
	[Category: Embedded.Hypervisor]		[Category: Embedded.Hypervisor]
	Critical level interrupts with the exception of Guest Processor Doorbell Critical are enabled regardless of the state of MSR _{CE} when MSR _{GS} = 1.		Machine Check interrupts with the exception of Guest Processor Doorbell Machine Check are enabled regardless of the state of MSR _{ME} when MSR _{GS} = 1.
47	Reserved	52	Floating-Point Exception Mode 0 (FE0)
48	External Enable (EE)		[Category: Floating-Point]
	0 External Input, Decrementer, Fixed-Interval Timer, Processor Doorbell, Guest Processor Doorbell <E.HV> and Embedded Performance Monitor <E.PM> interrupts are disabled.		(See below)
	1 External Input, Decrementer, Fixed-Interval Timer, Processor Doorbell, Guest Processor Doorbell <E.HV>, and Embedded Performance Monitor <E.PM> interrupts are enabled.	53	Implementation-dependent
		54	Debug Interrupt Enable (DE)
	[Category: Embedded.Hypervisor]		0 Debug interrupts are disabled
	When an interrupt that is maskable by MSR _{EE} is directed to the hypervisor state, the interrupt is enabled if MSR _{EE} =1 or MSR _{GS} =1 except for Guest Processor Doorbell which is enabled if MSR _{EE} =1 and MSR _{GS} =1. When an interrupt that is maskable by MSR _{EE} is directed to the guest supervisor state, the interrupt is enabled if MSR _{EE} =1 and MSR _{GS} =1. Also, see the EXTGS bit in Section 4.2.3.		1 Debug interrupts are enabled if DBCR _{IDM} =1
49	Problem State (PR)	55	Floating-Point Exception Mode 1 (FE1)
	0 The thread is in privileged state (supervisor state).		[Category: Floating-Point]
	1 The thread is in problem state (user mode).		(See below)
	MSR _{PR} also affects storage access control, as described in Section 6.7.6	56	Reserved
50	Floating-Point Available (FP)	57	Reserved
	[Category: Floating-Point]	58	Instruction Address Space (IS)
	0 The thread cannot execute any floating-point instructions, including floating-point loads, stores and moves.		0 The thread directs all instruction fetches to address space 0 (TS=0 in the relevant TLB entry).
	1 The thread can execute floating-point instructions.		1 The thread directs all instruction fetches to address space 1 (TS=1 in the relevant TLB entry).
		59	Data Address Space (DS)
			0 The thread directs all data storage accesses to address space 0 (TS=0 in the relevant TLB entry).
			1 The thread directs all data storage accesses to address space 1 (TS=1 in the relevant TLB entry).
		60	Implementation-dependent
		61	Performance Monitor Mark (PMM)
			[Category: Embedded.Performance Monitor]
			0 Disable statistics gathering on marked processes.
			1 Enable statistics gathering on marked processes
			See Appendix D for additional information.
		62	Reserved
		63	Reserved

The Floating-Point Exception Mode bits FE0 and FE1 are interpreted as shown below. For further details see Book I.

FE0	FE1	Mode
0	0	Ignore Exceptions
0	1	Imprecise Nonrecoverable
1	0	Imprecise Recoverable
1	1	Precise

See Section 8.3 for the initial state of the MSR.

[Category:Embedded.Hypervisor]

Some bits in the MSR can only be changed when the thread is in hypervisor state or the MSRP register has been configured to allow changes in the guest supervisor state. See Section 4.2.2, “Machine State Register Protect Register (MSRP)”.

Programming Note

A Machine State Register bit that is reserved may be altered by *rfl/rfci/rfmc/rfdi* [Category:Embedded.Enhanced Debug]/*rfgi* [Category:Embedded.Hypervisor].

4.2.2 Machine State Register Protect Register (MSRP)

The Machine State Register Protect Register (MSRP) controls whether certain bits in the Machine State Register (MSR) can be modified in guest supervisor state. In addition, the MSRP impacts the behavior of cache locking and performance monitor instructions in guest state, as described below. The format of the MSRP is shown in Figure 8 below.

Figure 8. Machine State Register Protect Register

The MSRP is used to prevent guest supervisor state program from modifying the UCLE, DE, or PMM bits in the MSR. The MSRP bits UCLEP, DEP, and PMMP control whether the guest can change the corresponding MSR bits UCLE, DE, and PMM, respectively. When the MSRP bit associated with a corresponding MSR bit is 0, any operation in guest privileged state is allowed to modify that MSR bit, whether from an instruction that modifies the MSR, or from an interrupt from the guest state which is taken in the guest supervisor state. When the MSRP bit associated with a corresponding MSR bit is 1 no operation in guest privileged state is allowed to modify that MSR bit (i.e., it remains unchanged), whether from an instruction that modifies the MSR, or from an interrupt from the guest state which is taken in the guest supervisor state.

These bits are interpreted as follows:

Bit	Definition
32:36	Reserved
37	User Cache Lock Enable Protect (UCLEP) [Category: ECL] <ul style="list-style-type: none"> 0 MSR_{UCLE} can be modified in guest supervisor state. 1 MSR_{UCLE} cannot be modified in guest supervisor state and guest state cache locking using <i>dcbtfls</i>, <i>dcbtstls</i>, <i>dcblic</i>, <i>icbtlis</i>, and <i>icblic</i> is affected as described later in this section."
38:53	Reserved
54	Debug Enable Protect (DEP) <ul style="list-style-type: none"> 0 MSR_{DE} can be modified in guest supervisor state. 1 MSR_{DE} cannot be modified in guest supervisor state.
55:60	Reserved
61	Performance Monitor Mark Protect (PMMP) [Category: E.PM] <ul style="list-style-type: none"> 0 MSR_{PMM} can be modified in guest supervisor state. 1 MSR_{PMM} cannot be modified in guest supervisor state and guest state accesses to Performance Monitor Registers using <i>mfpmr</i> and <i>mtpmr</i> are affected as described later in this section.
62:63	Reserved

The MSRP is hypervisor privileged.

A context synchronizing operation must be performed following a change to MSRP to ensure that its changes are visible in the current context.

The behavior of cache locking instructions (*dcbtfls*, *dcbtstls*, *dcblic*, *icbtlis*, *icblic*) in guest privileged state is dependent on the setting of MSRP_{UCLEP}. When MSRP_{UCLEP} = 0, cache locking instructions are permitted to execute normally in the guest privileged state. When MSRP_{UCLEP} = 1, cache locking instructions are not permitted to execute in the guest privileged state and cause an Embedded Hypervisor Privilege exception. [Category: ECL]

The behavior of Performance Monitor instructions (*mtpmr*, *mfpmr*) is dependent on the setting of MSRP_{PMMP}. When MSRP_{PMMP} = 0, Performance Monitor instructions are permitted to execute normally in the guest state. When MSRP_{PMMP} = 1, Performance Monitor instructions are not permitted to execute normally in the guest state. Execution of a *mfpmr* instruction which specifies a user Performance Monitor register produces a value of 0 in the destination GPR. In the guest supervisor state (MSR_{PR} = 0 and MSR_{GS} = 1), execution of any *mtpmr* instruction or execution of a *mfpmr* instruction which specifies a privileged

Performance Monitor Register produces an Embedded Hypervisor Privilege exception. [Category: E.PM]

Programming Note

Setting the MSRP to 0 at initialization allows guest state access to MSR_{UCLDE,DE,PMM} and the associated cache locking and performance monitor facilities.

4.2.3 Embedded Processor Control Register (EPCR)

The Embedded Processor Control Register (EPCR) provides general controls for privileged facilities. The format of the EPCR is shown in Figure 1 below.

Figure 9. Embedded Processor Control Register

These bits are interpreted as follows:

Bit Definition

- 32 **External Input Interrupt Directed to Guest State (EXTGS)**
[Category: Embedded.Hypervisor]
Controls whether an External Input Interrupt is taken in the guest supervisor state or the hypervisor state.
- 0 External Input Interrupts are directed to the hypervisor state. External Input Interrupts pend until MSR_{GS}=1 or MSR_{EE}=1.
 - 1 External Input Interrupts are directed to the guest supervisor state. External Input Interrupts pend until MSR_{GS}=1 and MSR_{EE}=1.
- 33 **Data TLB Error Interrupt Directed to Guest State (DTLBGS)**
[Category: Embedded.Hypervisor]
Controls whether a Data TLB Error Interrupt that occurs in the guest state is taken in the guest supervisor state or the hypervisor state.
- 0 Data TLB Error Interrupts that occur in the guest state are directed to the hypervisor state.
 - 1 Data TLB Error Interrupts that occur in the guest state are directed to the guest supervisor state.
- 34 **Instruction TLB Error Interrupt Directed to Guest State (ITLBGS)**
[Category: Embedded.Hypervisor]
Controls whether an Instruction TLB Error Interrupt that occurs in the guest state is taken in the guest supervisor state or the hypervisor state.

- 0 Instruction TLB Error Interrupts that occur in the guest state are directed to the hypervisor state.
- 1 Instruction TLB Error Interrupts that occur in the guest state are directed to the guest supervisor state.

35 **Data Storage Interrupt Directed to Guest State (DSIGS)**

[Category: Embedded.Hypervisor]

Controls whether a Data Storage Interrupt that occurs in the guest state is taken in the guest state or the hypervisor state, except for an interrupt caused by a TLB Ineligible exception <E.PT>.

- 0 Data Storage Interrupts that occur in the guest state are directed to the hypervisor state.
- 1 Data Storage Interrupts that occur in the guest state are directed to the guest supervisor state except that a Data Storage Interrupt due to a TLB Ineligible exception <E.PT> is directed to the hypervisor state, regardless of the existence of other exceptions that cause a Data Storage interrupt.

36 **Instruction Storage Interrupt Directed to Guest State (ISIGS)**

[Category: Embedded.Hypervisor]

Controls whether an Instruction Storage Interrupt that occurs in the guest state is taken in the guest state or the hypervisor state, except for an interrupt caused by a TLB Ineligible exception <E.PT>.

- 0 Instruction Storage Interrupts that occur in the guest supervisor state are directed to the hypervisor state.
- 1 Instruction Storage Interrupts that occur in the guest state are directed to the guest supervisor state.

37 **Disable Embedded Hypervisor Debug (DUVD)**

[Category: Embedded.Hypervisor]

Controls whether Debug Events occur in the hypervisor state.

- 0 Debug events can occur in the hypervisor state.
- 1 Debug events, except for the Unconditional Debug Event, are suppressed in the hypervisor state. It is implementation-dependent whether the Unconditional Debug Event is suppressed.

38 **Interrupt Computation Mode (ICM)**

[Category: 64-bit]

If category E.HV is implemented, this bit controls the computational mode of the thread when an interrupt occurs that is directed to the hypervisor state. At interrupt time, EPCR_{ICM} is

copied into MSR_{CM} if the interrupt is directed to the hypervisor state.

If category E.HV is not implemented, then this bit controls the computational mode of the thread when any interrupt occurs. At interrupt time, $EPCR_{ICM}$ is copied into MSR_{CM} .

- 0 Interrupts will execute in 32-bit mode.
- 1 Interrupts will execute in 64-bit mode.

39 **Guest Interrupt Computation Mode (GICM)**

[Category: E.Hypervisor]

[Corequisite Category: 64-bit]

Controls the computational mode of the thread when an interrupt occurs that is directed to the guest supervisor state. At interrupt time, $EPCR_{GICM}$ is copied into MSR_{CM} if the interrupt is directed to the guest supervisor state

- 0 Interrupts will execute in 32-bit mode.
- 1 Interrupts will execute in 64-bit mode.

40 **Disable Guest TLB Management Instructions (DGTMI)**

[Category: Embedded.Hypervisor]

Controls whether guest supervisor state can execute any TLB management instructions.

- 0 ***tlbilx***, ***tlbsrx***, and ***tlbwe*** (for a Logical to Real Address translation hit) are allowed to execute normally when $MSR_{GS,PR} = 0b10$.
- 1 ***tlbilx***, ***tlbsrx***, and ***tlbwe*** always cause an Embedded Hypervisor Privilege Interrupt when $MSR_{GS,PR} = 0b10$.

41 **Disable MAS Interrupt Updates for Hypervisor (DMIUH)**

[Category: Embedded.Hypervisor]

Controls whether MAS registers are updated by hardware when a Data or Instruction TLB Error Interrupt or a Data or Instruction Storage Interrupt is taken in the hypervisor.

- 0 MAS registers are set as described in Table 11 on page 986 when a Data or Instruction TLB Error Interrupt or a Data or Instruction Storage Interrupt is taken in the hypervisor.
- 1 MAS registers updates as described in Table 11 are disabled and MAS registers are left unchanged when a Data or Instruction TLB Error Interrupt or a Data or Instruction Storage Interrupt is taken in the hypervisor.

42:63 Reserved

This register is hypervisor privileged.

Engineering Note

EPCR only needs to be implemented if category Embedded.Hypervisor or category 64-bit are implemented.

4.3 Branch Facility Instructions

4.3.1 System Linkage Instructions

These instructions provide the means by which a program can call upon the system to perform a service,

and by which the system can return from performing a service or from processing an interrupt.

The *System Call* instruction is described in Book I, but only at the level required by an application programmer. A complete description of this instruction appears below.

System Call

SC-form

sc

sc LEV

[Category:Embedded.Hypervisor]

if LEV = 0 then

```

if MSRGS = 1 then
  GSRR0 ← ieaCIA + 4
  GSRR1 ← MSR
  if IVORs supported then
    NIA ← GIVPR0:47 || GIVOR8:48:59 || 0b0000
  else
    NIA ← GIVPR0:51 || 0x0120
    MSR ← new_value (see below)

```

```

else
  SRR0 ← ieaCIA + 4
  SRR1 ← MSR
  if IVORs supported then
    NIA ← IVPR0:47 || IVOR8:48:59 || 0b0000
  else
    NIA ← IVPR0:51 || 0x0120
    MSR ← new_value (see below)

```

```

else if LEV = 1 then
  SRR0 ← ieaCIA + 4
  SRR1 ← MSR
  if IVORs supported then
    NIA ← IVPR0:47 || IVOR40:48:59 || 0b0000
  else
    NIA ← IVPR0:51 || 0x300
    MSR ← new_value (see below)

```

If category E.HV is not implemented, the System Call instruction behaves as if MSR_{GS} = 0 and LEV = 0.

If MSR_{GS} = 0 or if LEV = 1, the effective address of the instruction following the *System Call* instruction is placed into SRR0 and the contents of the MSR are copied into SRR1. Otherwise, the effective address of the instruction following the *System Call* instruction is placed into GSRR0 and the contents of the MSR are copied into GSRR1.

If LEV=0, a System Call interrupt is generated. If LEV=1, an Embedded Hypervisor System Call interrupt

is generated. The interrupt causes the MSR to be set as described in Section 7.6.10 and Section 7.6.27.

If LEV=0 and the thread is in guest state, the interrupt causes the next instruction to be fetched from the effective address based on one of the following.

- GIVPR_{0:47}||GIVOR_{8:48:59}||0b0000 if IVORs [Category: Embedded.Phased-Out] are supported.
- GIVPR_{0:51}||0x120 if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported.

If LEV=0 and the thread is in hypervisor state, the interrupt causes the next instruction to be fetched from the effective address based on one of the following.

- IVPR_{0:47}||IVOR_{8:48:59}||0b0000 if IVORs [Category: Embedded.Phased-Out] are supported.
- IVPR_{0:51}||0x120 if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported.

If LEV=1, the interrupt causes the next instruction to be fetched from the effective address based on one of the following.

- IVPR_{0:47}||IVOR_{40:48:59}||0b0000 if IVORs [Category: Embedded.Phased-Out] are supported.
- IVPR_{0:51}||0x300 if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported.

This instruction is context synchronizing.

Special Registers Altered:

SRR0 GSRR0 SRR1 GSRR1 MSR

Programming Note

sc serves as both a basic and an extended mnemonic. The Assembler will recognize an **sc** mnemonic with one operand as the basic form, and an **sc** mnemonic with no operand as the extended form. In the extended form, the LEV operand is omitted and assumed to be 0.

Return From Interrupt**XL-form***rfi*

MSR \leftarrow SRR1
 NIA \leftarrow_{iea} SRR0_{0:61} || 0b00

The *rfi* instruction is used to return from a base class interrupt, or as a means of simultaneously establishing a new context and synchronizing on that new context.

The contents of SRR1 are placed into the MSR. If the new MSR value does not enable any pending exceptions, then the next instruction is fetched, under control of the new MSR value, from the address SRR0_{0:61}||0b00. (Note: VLE behavior may be different; see Book VLE.) If the new MSR value enables one or more pending exceptions, the interrupt associated with the highest priority pending exception is generated; in this case the value placed into the applicable save/restore register 0 by the interrupt processing mechanism (see Section 7.6 on page 1030) is the address of the instruction that would have been executed next had the interrupt not occurred (i.e. the address in SRR0 at the time of the execution of the *rfi*).

This instruction is privileged and context synchronizing.

[Category:Embedded.Hypervisor]

When *rfi* is executed in guest state, the instruction is mapped to *rtgi* and *rtgi* is executed instead.

Special Registers Altered:

MSR

Return From Critical Interrupt**XL-form***rfci*

MSR \leftarrow CSRR1
 NIA \leftarrow_{iea} CSRR0_{0:61} || 0b00

The *rfci* instruction is used to return from a critical class interrupt, or as a means of establishing a new context and synchronizing on that new context simultaneously.

The contents of CSRR1 are placed into the MSR. If the new MSR value does not enable any pending exceptions, then the next instruction is fetched, under control of the new MSR value, from the address CSRR0_{0:61}||0b00. (Note: VLE behavior may be different; see Book VLE.) If the new MSR value enables one or more pending exceptions, the interrupt associated with the highest priority pending exception is generated; in this case the value placed into SRR0 or CSRR0 by the interrupt processing mechanism (see Section 7.6 on page 1030) is the address of the instruction that would have been executed next had the interrupt not occurred (i.e. the address in CSRR0 at the time of the execution of the *rfci*).

This instruction is hypervisor privileged and context synchronizing.

Special Registers Altered:

MSR

Return From Debug Interrupt X-form

rfdi

[Category: Embedded.Enhanced Debug]

MSR ← DSRR1

NIA ←_{iea} DSRR0_{0:61} || 0b00

The **rfdi** instruction is used to return from a Debug interrupt, or as a means of establishing a new context and synchronizing on that new context simultaneously.

The contents of DSRR1 are placed into the MSR. If the new MSR value does not enable any pending exceptions, then the next instruction is fetched, under control of the new MSR value, from the address DSRR0_{0:61}||0b00. (Note: VLE behavior may be different; see Book VLE.) If the new MSR value enables one or more pending exceptions, the interrupt associated with the highest priority pending exception is generated; in this case the value placed into SRR0, CSRR0, or DSRR0 by the interrupt processing mechanism is the address of the instruction that would have been executed next had the interrupt not occurred (i.e. the address in DSRR0 at the time of the execution of the **rfdi**).

This instruction is hypervisor privileged and context synchronizing.

Special Registers Altered:

MSR

Return From Machine Check Interrupt XL-form

rfmci

MSR ← MCSRR1

NIA ←_{iea} MCSRR0_{0:61} || 0b00

The **rfmci** instruction is used to return from a Machine Check class interrupt, or as a means of establishing a new context and synchronizing on that new context simultaneously.

The contents of MCSRR1 are placed into the MSR. If the new MSR value does not enable any pending exceptions, then the next instruction is fetched, under control of the new MSR value, from the address MCSRR0_{0:61}||0b00. (Note: VLE behavior may be different; see Book VLE.) If the new MSR value enables one or more pending exceptions, the interrupt associated with the highest priority pending exception is generated; in this case the value placed into SRR0, CSRR0, MCSRR0, or DSRR0 [Category: Embedded.Enhanced Debug] by the interrupt processing mechanism (see Section 7.6 on page 1030) is the address of the instruction that would have been executed next had the interrupt not occurred (i.e. the address in MCSRR0 at the time of the execution of the **rfmci**).

This instruction is hypervisor privileged and context synchronizing.

Special Registers Altered:

MSR

Return From Guest Interrupt *XL-form*

rfgi [Category: Embedded.Hypervisor]

0	19	6	///	11	///	16	///	21	102	31
---	----	---	-----	----	-----	----	-----	----	-----	----

```

newmsr ← GSRR1
if MSRGS = 1 then
    newmsrGS,WE ← MSRGS,WE
    prots ← MSRPUCLEP,DEP,PMP
    newmsr ← prots & MSR | ~prots & newmsr
MSR ← newmsr
NIA ←iea GSRR00:61 || 0b00

```

The **rfgi** instruction is used to return from a guest state base class interrupt, or as a means of simultaneously establishing a new context and synchronizing on that new context.

The contents of Guest Save/Restore Register 1 are placed into the MSR. If the **rfgi** is executed in the guest supervisor state (MSR_{GS PR} = 0b10), the bits MSR_{GS WE} are not modified and the bits MSRP_{UCLEP,DEP,PMP} are modified only if the associated bits in the Machine State Register Protect (MSRP) Register are set to 0. If the new MSR value does not enable any pending exceptions, then the next instruction is fetched, under control of the new MSR value, from the address GSRR0_{0:61}||0b00. (Note: VLE behavior may be different; see Book VLE.) If the new MSR value enables one or more pending exceptions, the interrupt associated with the highest priority pending exception is generated; in this case the value placed into the associated save/restore register 0 by the interrupt processing mechanism is the address of the instruction that would have been executed next had the interrupt not occurred (i.e. the address in GSRR0 at the time of the execution of the **rfgi**).

This instruction is privileged and context synchronizing.

Special Registers Altered:

MSR

Embedded Hypervisor Privilege *XL-form*

ehpriv OC [Category: Embedded.Hypervisor]

0	31	6	OC	21	270	31
---	----	---	----	----	-----	----

The **ehpriv** instruction generates an Embedded Hypervisor Privilege Exception resulting in an Embedded Hypervisor Privilege Interrupt.

The OC field may be used by hypervisor software to provide a facility for emulated virtual instructions.

Special Registers Altered:

None

Programming Note

The **ehpriv** instruction is analogous to a guaranteed illegal instruction encoding in that it guarantees that an Embedded Hypervisor Privilege exception is generated. The instruction is useful for programs that need to communicate information to the hypervisor software, particularly as a means for implementing breakpoint operations in a hypervisor managed debugger.

Programming Note

ehpriv serves as both a basic and an extended mnemonic. The Assembler will recognize an **ehpriv** mnemonic with one operand as the basic form, and an **ehpriv** mnemonic with no operand as the extended form. In the extended form, the OC operand is omitted and assumed to be 0.

5.1 Fixed-Point Facility Overview

This chapter describes the details concerning the registers and the privileged instructions implemented in the Fixed-Point Facility that are not covered in Book I.

5.2 Special Purpose Registers

Special Purpose Registers (SPRs) are read and written using the *mfspr* (page 922) and *mtspr* (page 921) instructions. Most SPRs are defined in other chapters of this book; see the index to locate those definitions.

5.3 Fixed-Point Facility Registers

5.3.1 Processor Version Register

The Processor Version Register (PVR) is a 32-bit read-only register that contains a value identifying the version and revision level of the hardware. The contents of the PVR can be copied to a GPR by the *mfspr*

instruction. Read access to the PVR is privileged; write access is not provided.

Figure 10. Processor Version Register

The PVR distinguishes between implementations that differ in attributes that may affect software. It contains two fields.

Version A 16-bit number that identifies the version of the implementation. Different version numbers indicate major differences between implementations, such as which optional facilities and instructions are supported.

Revision A 16-bit number that distinguishes between implementations of the version. Different revision numbers indicate minor differences between implementations having the same version number, such as clock rate and Engineering Change level.

Version numbers are assigned by the Power ISA Architecture process. Revision numbers are assigned by an implementation-defined process.

5.3.2 Processor Identification Register

The Processor Identification Register (PIR) is a 32-bit register that contains a value that can be used to distinguish the thread from other threads in the system. The contents of the PIR can be read using *mf spr* and written using *mt spr*. Read access to the PIR is privileged; write access, if provided, is hypervisor privileged.

[Category:Embedded.Hypervisor]

Read accesses to the PIR in guest supervisor state are mapped to the GPIR.

Bits	Name	Description
32:63	PROCID	Thread ID

Figure 11. Processor Identification Register

The means by which the PIR is initialized are implementation-dependent.

Programming Note

The PIR can be used to identify the thread globally among all threads in a system that contains multiple threads. This facilitates more efficient usage of the Processor Control facility (see Section 11).

5.3.3 Guest Processor Identification Register [Category:Embedded.Hypervisor]

The Guest Processor Identification Register (GPIR) is a 32-bit register that contains a value that can be used to distinguish the thread from other threads in the system. The contents of the GPIR can be read using *mf spr* and written using *mt spr*. Read access to the GPIR is privileged; write access, if provided, is hypervisor privileged.

Bits	Name	Description
32:63	PROCID	Thread ID

Figure 12. Guest Processor Identification Register

The means by which the GPIR is initialized are implementation-dependent.

Programming Note

mf spr RT,PIR should be used to read GPIR in guest supervisor state. See Section 2.2.1, "Register Mapping". *mt spr PIR,RS* should be used to write GPIR in guest supervisor state.

Engineering Note

Some previous implementations did not allow write access to the PIR. This allows the hypervisor to easily track changes to the GPIR. If write access is allowed to the PIR, write access should be allowed to the GPIR and should only be available to the hypervisor.

5.3.4 Program Priority Register 32-bit [Category: Phased-In]

Privileged programs may set a wider range of program priorities in the PRI field of PPR32 than may be set by problem-state programs (see Section 3.1 of Book II). Problem-state programs may only set values in the range of 0b010 to 0b100. Privileged programs may set values in the range of 0b001 to 0b110. Hypervisor software may also set 0b111. If a program attempts to set a value that is not available to it, the PRI field remains unchanged. The values and their corresponding meanings are as follows.

001	very low
010	low
011	medium low (normal)
100	medium
101	medium high
110	high
111	very high

5.3.5 Software-use SPRs

Software-use SPRs are 64-bit registers provided for use by software.

SPRG0
SPRG1
SPRG2
SPRG3
SPRG4
SPRG5
SPRG6
SPRG7
SPRG8
SPRG9 [Category: Embedded.Enhanced Debug]

GSPRG2 [Category:Embedded.Hypervisor]
GSPRG3 [Category:Embedded.Hypervisor]

0

63

Figure 13. Special Purpose Registers

Programming Note

USPRG0 was made a 32-bit register and renamed to VRSAVE; see Sections 3.2.3 and 6.3.3 of Book I.

SPRG0 through SPRG2

These 64-bit registers can be accessed only in supervisor mode.

[Category:Embedded.Hypervisor]

Access to these registers in guest supervisor state is mapped to GSPRG0 through GSPRG2.

SPRG3

This 64-bit register can be read in supervisor mode and can be written only in supervisor mode. It is implementation-dependent whether or not this register can be read in user mode.

[Category:Embedded.Hypervisor]

Access to this register in guest state is mapped to GSPRG3.

SPRG4 through SPRG7

These 64-bit registers can be written only in supervisor mode. These registers can be read in supervisor and user modes.

SPRG8 through SPRG9

These 64-bit registers can be accessed only in supervisor mode.

GSPRG0 through GSPRG2

[Category:Embedded.Hypervisor]

These 64-bit registers can be accessed only in supervisor mode.

GSPRG3

[Category:Embedded.Hypervisor]

This 64-bit register can be read in supervisor mode and can be written only in supervisor mode. It is implementation-dependent whether or not this register can be read in user mode.

SPRGi or GSPRGi can be read using *mfspr* and written using *mtspr*.

Programming Note

mfspr RT,SPRGi should be used to read GSPRGi in guest state. *mtspr SPRGi,RS* should be used to write GSPRGi in guest state. See Section 2.2.1, “Register Mapping”.

5.3.6 External Process ID Registers [Category: Embedded.External PID]

The External Process ID Registers provide capabilities for loading and storing General Purpose Registers and performing cache management operations using a supplied context other than the context normally used by the programming model.

Two SPRs describe the context for loading and storing using external contexts. The External Process ID Load Context (EPLC) Register provides the context for *External Process ID Load* instructions, and the External Process ID Store Context (EPSC) Register provides the context for *External Process ID Store* instructions. Each of these registers contains a PR (privilege) bit, an AS (address space) bit, a Process ID, a GS (guest state) bit <E.HV>, and an LPID <E.HV>. Changes to the EPLC or the EPSC Register require that a context synchronizing operation be performed prior to using any *External Process ID* instructions that use these registers.

External Process ID instructions that use the context provided by the EPLC register include *lbepx*, *lhexp*, *lwepx*, *ldexp*, *dcbtep*, *dcbtstep*, *dcbfep*, *dcbstep*, *icbiep*, *lfdep*, *evlddep*, *lvepx*, and *lvexpl* and those that use the context provided by the EPSC register include *stbepx*, *sthepx*, *stwepx*, *stdep*, *dcbzep*, *stfdep*, *evstdep*, *stvepx*, and *stvepxl*. Instruction definitions appear in Section 5.4.3.

System software configures the EPLC register to reflect the Process ID, AS, PR, GS <E.HV>, and LPID <E.HV> state from the context that it wishes to perform loads from and configures the EPSC register to reflect the Process ID, AS, PR, GS <E.HV>, and LPID <E.HV> state from the context it wishes to perform stores to. Software then issues *External Process ID* instructions to manipulate data as required.

When the an *External Process ID Load* instruction is executed, it uses the context information in the EPLC Register instead of the normal context with respect to address translation and storage access control. $EPLC_{EPR}$ is used in place of MSR_{PR} , $EPLC_{EAS}$ is used in place of MSR_{DS} , $EPLC_{EPID}$ is used in place of PID, $EPLC_{EGS}$ is used in place of MSR_{GS} <E.HV>, and $EPLC_{ELPID}$ is used in place of LPIDR <E.HV>. Similarly, when the an *External Process ID Store* instruction is executed, it uses the context information in the EPSC Register instead of the normal context with respect to address translation and storage access control. $EPSC_{EPR}$ is used in place of MSR_{PR} , $EPSC_{EAS}$ is used in place of MSR_{DS} , $EPSC_{EPID}$ is used in place of PID, $EPSC_{EGS}$ is used in place of MSR_{GS} <E.HV>, and $EPSC_{ELPID}$ is used in place of LPIDR <E.HV>. Translation occurs using the new substituted values.

If the TLB lookup is successful, the storage access control mechanism grants or denies the access using context information from $EPLC_{EPR}$ or $EPSC_{EPR}$ for loads and stores respectively. If access is not granted, a Data Storage interrupt occurs, and the ESR_{EPID} bit is set to 1. If the operation was a *Store*, the ESR_{ST} bit is also set to 1.

5.3.6.1 External Process ID Load Context (EPLC) Register

The EPLC register contains fields to provide the context for *External Process ID Load* instructions.

Figure 14. External Process ID Load Context Register

These bits are interpreted as follows:

Bit	Definition
32	External Load Context PR Bit (EPR) Used in place of MSR_{PR} by the storage access control mechanism when an <i>External Process ID Load</i> instruction is executed. 0 Supervisor mode 1 User mode
33	External Load Context AS Bit (EAS) Used in place of MSR_{DS} for translation when an <i>External Process ID Load</i> instruction is executed, and, if this <i>Load</i> instruction causes a Data TLB Error interrupt, loaded into MAS registers in place of MSR_{DS} . 0 Address space 0 1 Address space 1
34	External Load Context GS Bit (EGS) [Category Embedded.Hypervisor] Used in place of MSR_{GS} for translation when an <i>External Process ID Load</i> instruction is executed. 0 Hypervisor state 1 Guest state
35	Reserved
36:47	External Load Context LPID Value (ELPID) [Category:Embedded.Hypervisor] Used in place of LPIDR register for translation when an <i>External Process ID Load</i> instruction is executed.
48:49	Reserved
50:63	External Load Context Process ID Value (EPID) Used in place of the Process ID register value for translation when an external Process ID

Load instruction is executed, and, if this *Load* instruction causes a Data TLB Error interrupt, loaded into MAS registers in place of PID contents.

When a *mtspr* instruction is executed that targets EPLC, the EGS and ELPID fields are only modified if the thread is in hypervisor state.

5.3.6.2 External Process ID Store Context (EPSC) Register

The EPSC register contains fields to provide the context for *External Process ID Store* instructions. The field encoding is the same as the EPLC Register.

Figure 15. External Process ID Store Context Register

These bits are interpreted as follows:

Bits	Definition
32	External Store Context PR Bit (EPR) Used in place of MSR _{PR} by the storage access control mechanism when an <i>External Process ID Store</i> instruction is executed. 0 Supervisor mode 1 User mode
33	External Store Context AS Bit (EAS) Used in place of MSR _{DS} for translation when an <i>External Process ID Store</i> instruction is executed, and, if this <i>Store</i> instruction causes a Data TLB Error interrupt, loaded into MAS registers in place of MSR _{DS} . 0 Address space 0 1 Address space 1
34	External Store Context GS Bit (EGS) [Category Embedded.Hypervisor] Used in place of MSR _{GS} for translation when an <i>External Process ID Store</i> instruction is executed. 0 Hypervisor state 1 Guest state
35	Reserved
36:47	External Store Context LPID Value (ELPID) [Category:Embedded.Hypervisor] Used in place of LPIDR register for translation when an <i>External Process ID Store</i> instruction is executed.
48:49	Reserved
50:63	External Store Context Process ID Value (EPID) Used in place of the Process ID register value

for translation when an external PID *Store* instruction is executed, and, if this *Store* instruction causes a Data TLB Error interrupt, loaded into MAS registers in place of PID contents.

When a *mtspr* instruction is executed that targets EPSC, the EGS and ELPID fields are only modified if the thread is in hypervisor state.

5.4 Fixed-Point Facility Instructions

5.4.1 Move To/From System Register Instructions

The *Move To Special Purpose Register* and *Move From Special Purpose Register* instructions are described in Book I, but only at the level available to an application programmer. For example, no mention is made there of registers that can be accessed only in supervisor mode. The descriptions of these instructions given below extend the descriptions given in Book I, but do not list Special Purpose Registers that are implementation-dependent. In the descriptions of these instructions given below, the “defined” SPR numbers are the SPR numbers shown in Table 16 and the implementation-

specific SPR numbers that are implemented, and similarly for “defined” registers.

Extended mnemonics

Extended mnemonics are provided for the *mtspr* and *mfspir* instructions so that they can be coded with the SPR name as part of the mnemonic rather than as a numeric operand; see Appendix B.

decimal	SPR ¹		Register Name	Privileged		Length (bits)	Cat ²
	spr _{5:9}	spr _{0:4}		mtspr	mfspir		
1	00000	00001	XER	no	no	64	B

- This register is not defined for this instruction.
¹ Note that the order of the two 5-bit halves of the SPR number is reversed.
² See Section 1.3.5 of Book I. If multiple categories are listed separated by a semi-colon, all the listed categories must be implemented in order for the other columns of the line to apply. A comma separates two alternatives, and takes precedence over a semicolon; e.g., the EPCR (E.HV,E;64) must be implemented if either (a) category E.HV is implemented or (b) the implementation is Embedded and supports the 64-bit category.
³ This register is a hypervisor resource, and can be accessed by this instruction only in hypervisor state (see Chapter 2 of Book III-E).
⁴ If the Embedded.Hypervisor category is supported, this register is a hypervisor resource, and can be accessed by this instruction only in hypervisor state (see Chapter 2 of Book III-E). Otherwise, the register is privileged.
⁵ The register can be written by the **dcread** instruction.
⁶ The register can be written by the **icread** instruction.
⁷ The register is Category: Phased-in.
⁸ If the Embedded.Hypervisor category is supported, this register is a hypervisor resource, and can be accessed by this instruction only in hypervisor state (see Chapter 2 of Book III-E). Otherwise, the register is privileged for Embedded.
⁹ If the Embedded.Hypervisor category is supported, this register is a hypervisor resource and can be accessed by this instruction only in hypervisor state, and guest references to the register are redirected to the corresponding guest register (see Chapter 2 of Book III-E). Otherwise the register is privileged.
All SPR numbers that are not shown above and are not implementation-specific are reserved.

Figure 16. SPR Numbers (Sheet 3 of 3)

Move To Special Purpose Register XFX-form

mtspr SPR,RS

31	RS	spr	467	/	31
0	6	11	21		

```

n ← spr5:9 || spr0:4
if length(SPR(n)) = 64 then
  SPR(n) ← (RS)
else
  SPR(n) ← (RS)32:63

```

The SPR field denotes a Special Purpose Register, encoded as shown in Figure 16. The contents of register RS are placed into the designated Special Purpose Register. For Special Purpose Registers that are 32 bits long, the low-order 32 bits of RS are placed into the SPR.

For this instruction, SPRs TBL and TBU are treated as separate 32-bit registers; setting one leaves the other unaltered.

spr₀=1 if and only if writing the register is privileged. Execution of this instruction specifying a defined and

privileged register when $MSR_{PR}=1$ causes a Privileged Instruction type Program interrupt.

Execution of this instruction specifying an SPR number that is not defined for the implementation causes either an Illegal Instruction type Program interrupt or one of the following.

- if $spr_0=0$: boundedly undefined results
- if $spr_0=1$:
 - if $MSR_{PR}=1$: Privileged Instruction type Program interrupt; if $MSR_{PR}=0$: boundedly undefined results

If the SPR number is set to a value that is shown in Figure 16 but corresponds to an optional Special Purpose Register that is not provided by the implementation, the effect of executing this instruction is the same as if the SPR number were reserved.

Special Registers Altered:

See Figure 16

Compiler and Assembler Note

For the *mtspr* and *mfspr* instructions, the SPR number coded in assembler language does not appear directly as a 10-bit binary number in the instruction. The number coded is split into two 5-bit halves that are reversed in the instruction, with the high-order 5 bits appearing in bits 16:20 of the instruction and the low-order 5 bits in bits 11:15.

Programming Note

For a discussion of software synchronization requirements when altering certain Special Purpose Registers, see Chapter 12. “Synchronization Requirements for Context Alterations” on page 1099.

Move From Special Purpose Register XFX-form

mfspr RT,SPR

0	31	RT	spr	339	/
	6	11	21	31	

```
n ← spr5:9 || spr0:4
if length(SPR(n)) = 64 then
  RT ← SPR(n)
else
  RT ← 320 || SPR(n)
```

The SPR field denotes a Special Purpose Register, encoded as shown in Figure 16. The contents of the designated Special Purpose Register are placed into register RT. For Special Purpose Registers that are 32 bits long, the low-order 32 bits of RT receive the contents of the Special Purpose Register and the high-order 32 bits of RT are set to zero.

spr₀=1 if and only if reading the register is privileged. Execution of this instruction specifying a defined and privileged register when MSR_{PR}=1 causes a Privileged Instruction type Program interrupt.

Execution of this instruction specifying an SPR number that is not defined for the implementation causes either an Illegal Instruction type Program interrupt or one of the following.

- if spr₀=0: boundedly undefined results
- if spr₀=1:
 - if MSR_{PR}=1: Privileged Instruction type Program interrupt
 - if MSR_{PR}=0: boundedly undefined results

If the SPR field contains a value that is shown in Figure 16 but corresponds to an optional Special Purpose Register that is not provided by the implementation, the effect of executing this instruction is the same as if the SPR number were reserved.

Special Registers Altered:

None

Note

See the Notes that appear with *mtspr*.

Move To Device Control Register XFX-form

mtdcr DCRN,RS

[Category: Embedded.Device Control]

0	31	RS	dcr	451	/
	6	11	21	31	

```
DCRN ← dcr0:4 || dcr5:9
DCR(DCRN) ← (RS)
```

Let DCRN denote a Device Control Register. (The supported Device Control Registers are implementation-dependent.)

The contents of register RS are placed into the designated Device Control Register. For 32-bit Device Control Registers, the contents of bits 32:63 of (RS) are placed into the Device Control Register.

This instruction is privileged.

Special Registers Altered:

Implementation-dependent.

Move To Device Control Register Indexed X-form

mtdcrx RA,RS

[Category: Embedded.Device Control]

0	31	RS	RA	///	387	/
	6	11	16	21	31	

```
DCRN ← (RA)
DCR(DCRN) ← (RS)
```

Let the contents of register RA denote a Device Control Register. (The supported Device Control Registers supported are implementation-dependent.)

The contents of register RS are placed into the designated Device Control Register. For 32-bit Device Control Registers, the contents of RS_{32:63} are placed into the Device Control Register.

The specification of Device Control Registers using *mtdcrx*, *mtdcrux* (see Book I), and *mtdcr* is implementation-dependent. For example, *mtdcr 105,r2* and *mtdcrux r1,r2* (where register r1 contains the value 105) may not produce identical results on an implementation.

This instruction is privileged.

Special Registers Altered:

Implementation-dependent.

Move From Device Control Register XFX-form

`mfdcr` RT,DCRN
[Category: Embedded.Device Control]

31	RT	dcr	323	/
0	6	11	21	31

$DCRN \leftarrow dcr_{0:4} \parallel dcr_{5:9}$
 $RT \leftarrow DCR(DCRN)$

Let DCRN denote a Device Control Register. (The supported Device Control Registers are implementation-dependent.)

The contents of the designated Device Control Register are placed into register RT. For 32-bit Device Control Registers, the contents of the Device Control Register are placed into bits 32:63 of RT. Bits 0:31 of RT are set to 0.

This instruction is privileged.

Special Registers Altered:
Implementation-dependent.

Move From Device Control Register Indexed X-form

`mfdcrx` RT,RA
[Category: Embedded.Device Control]

31	RT	RA	///	259	/
0	6	11	16	21	31

$DCRN \leftarrow (RA)$
 $RT \leftarrow DCR(DCRN)$

Let the contents of register RA denote a Device Control Register (the supported Device Control Registers are implementation-dependent.)

The contents of the designated Device Control Register are placed into register RT. For 32-bit Device Control Registers, the contents of bits 32:63 of the designated Device Control Register are placed into RT. Bits 0:31 of RT are set to 0.

The specification of Device Control Registers using `mfdcrx` and `mfdcrux` (see Book I) compared to the specification of Device Control Registers using `mfdcr` is implementation-dependent. For example, `mfdcr r2,105` and `mfdcrx r2,r1` (where register r1 contains the value 105) may not produce identical results on an implementation or between implementations. Also, accessing privileged Device Control Registers in supervisor mode with `mfdcrux` is implementation-dependent.

This instruction is privileged.

Special Registers Altered:
Implementation-dependent.

Move To Machine State Register X-form

`mtmsr` RS

31	RS	///	///	146	/
0	6	11	16	21	31

```
newmsr ← (RS)32:63
if MSRCM = 0 & newmsrCM = 1 then NIA0:31 ← 0
if MSRGS = 1 then
  newmsrGS WE ← MSRGS WE
  prots0:31 ← 0
  protsUCLEP DEP PMMP ← MSRUCLEP DEP PMMP
  newmsr ← prots & MSR | ~prots & newmsr
MSR ← newmsr
```

The contents of register RS_{32:63} are placed into the MSR. If the thread is changing from 32-bit mode to 64-bit mode, the next instruction is fetched from 320IINIA_{32:63}.

This instruction is privileged and execution synchronizing.

In addition, alterations to the EE or CE bits are effective as soon as the instruction completes. Thus if MSR_{EE}=0 and an External interrupt is pending, executing an `mtmsr` that sets MSR_{EE} to 1 will cause the External interrupt to be taken before the next instruction is executed, if no higher priority exception exists. Likewise, if MSR_{CE}=0 and a Critical Input interrupt is pending, executing an `mtmsr` that sets MSR_{CE} to 1 will cause the Critical Input interrupt to be taken before the next instruction is executed if no higher priority exception exists. (See Section 7.6 on page 1030.)

[Category:Embedded.Hypervisor]

GS, WE and bits protected with MSRP are only modified if `mtmsr` is executed in hypervisor state.

Special Registers Altered:
MSR

Programming Note

For a discussion of software synchronization requirements when altering certain MSR bits please refer to Chapter 12.

**Move From Machine State Register
X-form**

mfmsr RT

$RT \leftarrow {}^{32}_0 \parallel MSR$

The contents of the MSR are placed into bits 32:63 of register RT and bits 0:31 of RT are set to 0.

This instruction is privileged.

Special Registers Altered:

None

Write MSR External Enable X-form

wrtee RS

$MSR_{EE} \leftarrow (RS)_{48}$

The content of $(RS)_{48}$ is placed into MSR_{EE} .

Alteration of the MSR_{EE} bit is effective as soon as the instruction completes. Thus if $MSR_{EE}=0$ and an External interrupt is pending, executing a wrtee instruction that sets MSR_{EE} to 1 will cause the External interrupt to occur before the next instruction is executed, if no higher priority exception exists (Section 7.9, "Exception Priorities" on page 1059).

This instruction is privileged.

Special Registers Altered:

MSR

Write MSR External Enable Immediate X-form

wrteei E

0	31	///	///	E	///	163	/
	6	11	16	17	21	31	

$MSR_{EE} \leftarrow E$

The value specified in the E field is placed into MSR_{EE} .

Alteration of the MSR_{EE} bit is effective as soon as the instruction completes. Thus if $MSR_{EE}=0$ and an External interrupt is pending, executing a wrtee instruction that sets MSR_{EE} to 1 will cause the External interrupt to occur before the next instruction is executed, if no higher priority exception exists (Section 7.9, "Exception Priorities" on page 1059).

This instruction is privileged.

Special Registers Altered:

MSR

Programming Note

wrtee and **wrteei** are used to provide atomic update of MSR_{EE} . Typical usage is:

```
mfmsr   Rn      #save EE in (Rn)48
wrteei  0        #turn off EE
mfmsr   Rn      #save EE in (Rn)48
wrteei  0        #turn off EE
:       :        :
:       :        : #code with EE disabled
wrtee   Rn      #restore EE without altering
              #other MSR bits that might
              #have changed
```

5.4.2 OR Instruction

or Rx,Rx,Rx can be used to set PPR_{PRI} (see Figure 2 in Section 3.1 of Book II) as shown in Figure 17. PPR_{PRI} remains unchanged if the privilege state of the thread executing the instruction is lower than the privilege indicated in the figure. (The encodings available to problem-state programs, as well as encodings for additional shared resource hints not shown here, are described in Section 3.2 of Book II.)

Rx	PPR32 _{PRI}	Priority	Privileged
31	001	very low	yes
1	010	low	no
6	011	medium low (normal)	no
2	100	medium	no
5	101	medium high	yes
3	110	high	yes
7	111	very high	hypv ¹

¹ If the Embedded.Hypervisor category is supported, this value is hypervisor privileged. Otherwise, the value is privileged.

Figure 17. Priority levels for *or Rx,Rx,Rx*

5.4.3 External Process ID Instructions [Category: Embedded.External PID]

External Process ID instructions provide capabilities for loading and storing General Purpose Registers and performing cache management operations using a supplied context other than the context normally used by translation.

The EPLC and EPSC registers provide external contexts for performing loads and stores. The EPLC and the EPSC registers are described in Section 5.3.6.

If an Alignment interrupt, Data Storage interrupt, or a Data TLB Error interrupt, occurs while attempting to execute an *External Process ID* instruction, ESR_{EPID} is set to 1 indicating that the instruction causing the interrupt was an *External Process ID* instruction; any other applicable ESR bits are also set.

Load Byte by External Process ID Indexed X-form

lbepx RT,RA,RB

```
if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
RT ← 560 || MEM(EA, 1)
```

Let the effective address (EA) be the sum (RAI0)+(RB). The byte in storage addressed by EA is loaded into $RT_{56:63}$. $RT_{0:55}$ are set to 0.

For *lbepx*, the normal translation mechanism is not used. The contents of the EPLC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

- EPLC_{EPR} is used in place of MSR_{PR}
- EPLC_{EAS} is used in place of MSR_{DS}
- EPLC_{EPID} is used in place of PID
- EPLC_{EGS} is used in place of MSR_{GS} <E.HV>
- EPLC_{ELPID} is used in place of LPIDR <E.HV>

This instruction is privileged.

Special Registers Altered:

None

Programming Note

This instruction behaves identically to a *lbzx* instruction except for using the EPLC register to provide the translation context.

Load Halfword by External Process ID Indexed X-form

lhpx RT,RA,RB

```
if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
RT ← 480 || MEM(EA, 2)
```

Let the effective address (EA) be the sum (RAI0)+(RB). The halfword in storage addressed by EA is loaded into $RT_{48:63}$. $RT_{0:47}$ are set to 0.

For *lhpx*, the normal translation mechanism is not used. The contents of the EPLC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

- EPLC_{EPR} is used in place of MSR_{PR}
- EPLC_{EAS} is used in place of MSR_{DS}
- EPLC_{EPID} is used in place of PID
- EPLC_{EGS} is used in place of MSR_{GS} <E.HV>
- EPLC_{ELPID} is used in place of LPIDR <E.HV>

This instruction is privileged.

Special Registers Altered:

None

Programming Note

This instruction behaves identically to a *lhzx* instruction except for using the EPLC register to provide the translation context.

Load Word by External Process ID Indexed
X-form

lwepx RT,RA,RB

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
RT ← 320 || MEM(EA, 4)

```

Let the effective address (EA) be the sum (RAI0)+(RB). The word in storage addressed by EA is loaded into RT_{32:63}. RT_{0:31} are set to 0.

For **lwepx**, the normal translation mechanism is not used. The contents of the EPLC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

EPLC_{EPR} is used in place of MSR_{PR}
 EPLC_{EAS} is used in place of MSR_{DS}
 EPLC_{EPID} is used in place of PID
 EPLC_{EGS} is used in place of MSR_{GS} <E.HV>
 EPLC_{ELPID} is used in place of LPIDR <E.HV>

This instruction is privileged.

Special Registers Altered:

None

Programming Note

This instruction behaves identically to a **lwzx** instruction except for using the EPLC register to provide the translation context.

Load Doubleword by External Process ID Indexed
X-form

ldepX RT,RA,RB

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
RT ← MEM(EA, 8)

```

Let the effective address (EA) be the sum (RAI0)+(RB). The doubleword in storage addressed by EA is loaded into RT.

For **ldepX**, the normal translation mechanism is not used. The contents of the EPLC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

EPLC_{EPR} is used in place of MSR_{PR}
 EPLC_{EAS} is used in place of MSR_{DS}
 EPLC_{EPID} is used in place of PID
 EPLC_{EGS} is used in place of MSR_{GS} <E.HV>
 EPLC_{ELPID} is used in place of LPIDR <E.HV>

This instruction is privileged.

Corequisite Categories:

64-Bit

Special Registers Altered:

None

Programming Note

This instruction behaves identically to a **ldx** instruction except for using the EPLC register to provide the translation context.

Store Byte by External Process ID Indexed *X-form*

stbepx RS,RA,RB

```
if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
MEM(EA,1) ← (RS)56:63
```

Let the effective address (EA) be the sum (RAI0)+(RB). (RS)_{56:63} are stored into the byte in storage addressed by EA.

For **stbepx**, the normal translation mechanism is not used. The contents of the EPSC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

- EPSC_{EPR} is used in place of MSR_{PR}
- EPSC_{EAS} is used in place of MSR_{DS}
- EPSC_{EPID} is used in place of PID
- EPSC_{EGS} is used in place of MSR_{GS} <E.HV>
- EPSC_{ELPID} is used in place of LPIDR <E.HV>

This instruction is privileged.

Special Registers Altered:

None

Programming Note

This instruction behaves identically to a **stbx** instruction except for using the EPSC register to provide the translation context.

Store Halfword by External Process ID Indexed *X-form*

sthpx RS,RA,RB

```
if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
MEM(EA,2) ← (RS)48:63
```

Let the effective address (EA) be the sum (RAI0)+(RB). (RS)_{48:63} are stored into the halfword in storage addressed by EA.

For **sthpx**, the normal translation mechanism is not used. The contents of the EPSC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

- EPSC_{EPR} is used in place of MSR_{PR}
- EPSC_{EAS} is used in place of MSR_{DS}
- EPSC_{EPID} is used in place of PID
- EPSC_{EGS} is used in place of MSR_{GS} <E.HV>
- EPSC_{ELPID} is used in place of LPIDR <E.HV>

This instruction is privileged.

Special Registers Altered:

None

Programming Note

This instruction behaves identically to a **sthx** instruction except for using the EPSC register to provide the translation context.

Store Word by External Process ID Indexed *X-form*

stwepx RS,RA,RB

0	31	RS	RA	RB	159	/
	6	11	16	21	31	

```
if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
MEM(EA,4) ← (RS)32:63
```

Let the effective address (EA) be the sum (RAI0)+(RB). (RS)_{32:63} are stored into the word in storage addressed by EA.

For **stwepx**, the normal translation mechanism is not used. The contents of the EPSC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

- EPSC_{EPR} is used in place of MSR_{PR}
- EPSC_{EAS} is used in place of MSR_{DS}
- EPSC_{EPIID} is used in place of PID
- EPSC_{EGS} is used in place of MSR_{GS} <E.HV>
- EPSC_{ELPID} is used in place of LPIDR <E.HV>

This instruction is privileged.

Special Registers Altered:

None

Programming Note

This instruction behaves identically to a **stwx** instruction except for using the EPSC register to provide the translation context.

Store Doubleword by External Process ID Indexed *X-form*

stdepx RS,RA,RB

0	31	RS	RA	RB	157	/
	6	11	16	21	31	

```
if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
MEM(EA,8) ← (RS)
```

Let the effective address (EA) be the sum (RAI0)+(RB). (RS) is stored into the doubleword in storage addressed by EA.

For **stdepx**, the normal translation mechanism is not used. The contents of the EPSC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

- EPSC_{EPR} is used in place of MSR_{PR}
- EPSC_{EAS} is used in place of MSR_{DS}
- EPSC_{EPIID} is used in place of PID
- EPSC_{EGS} is used in place of MSR_{GS} <E.HV>
- EPSC_{ELPID} is used in place of LPIDR <E.HV>

This instruction is privileged.

Corequisite Categories:

64-Bit

Special Registers Altered:

None

Programming Note

This instruction behaves identically to a **stdx** instruction except for using the EPSC register to provide the translation context.

Data Cache Block Store by External PID X-form

dcbstep RA,RB

0	31	6	///	11	RA	16	RB	21	63	31
---	----	---	-----	----	----	----	----	----	----	----

Let the effective address (EA) be the sum $(RA10)+(RB)$.

If the block containing the byte addressed by EA is in storage that is Memory Coherence Required, a block containing the byte addressed by EA is in the data cache of any thread, and any locations in the block are considered to be modified there, then those locations are written to main storage. Additional locations in the block may be written to main storage. The block ceases to be considered modified in that data cache.

If the block containing the byte addressed by EA is in storage that is not Memory Coherence Required and the block is in the data cache of this thread, and any locations in the block are considered to be modified there, those locations are written to main storage. Additional locations in the block may be written to main storage, and the block ceases to be considered modified in that data cache.

The function of this instruction is independent of whether the block containing the byte addressed by EA is in storage that is Write Through Required or Caching Inhibited.

The instruction is treated as a *Load* with respect to translation, memory protection, and is treated as a *Write* with respect to debug events.

This instruction is privileged.

For **dcbstep**, the normal translation mechanism is not used. The contents of the EPLC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

EPLC_{EPR} is used in place of MSR_{PR}
 EPLC_{EAS} is used in place of MSR_{DS}
 EPLC_{EPID} is used in place of PID
 EPLC_{EGS} is used in place of MSR[GS] <E.HV>
 EPLC_{ELPID} is used in place of LPIDR <E.HV>

Special Registers Altered:

None

Programming Note

This instruction behaves identically to a **dcbst** instruction except for using the EPLC register to provide the translation context.

Data Cache Block Touch by External PID X-form

dcbstep TH,RA,RB

0	31	6	TH	11	RA	16	RB	21	319	31
---	----	---	----	----	----	----	----	----	-----	----

Let the effective address (EA) be the sum $(RA10)+(RB)$.

The dcbstep instruction provides a hint that the program will probably soon load from the block containing the byte addressed by EA. If the Cache Specification category is supported, the nature of the hint is affected by TH values of 0b00000 to 0b00111. Values associated with the Stream category are ignored. See Section 4.3.2 of Book II for more information.

If the block is in a storage location that is Caching Inhibited or Guarded, the hint is ignored.

The only operation that is “caused” by the **dcbstep** instruction is the providing of the hint. The actions (if any) taken in response to the hint are not considered to be “caused by” or “associated with” the **dcbstep** instruction (e.g., **dcbstep** is considered not to cause any data accesses). No means are provided by which software can synchronize these actions with the execution of the instruction stream. For example, these actions are not ordered by the memory barrier created by a **sync** instruction.

The **dcbstep** instruction may complete before the operation it causes has been performed.

The nature of the hint depends, in part, on the value of the TH field, as specified in the **dcbt** instruction in Section 4.3.2 of Book II.

The instruction is treated as a *Load*, except that no interrupt occurs if a protection violation occurs.

The instruction is privileged.

The normal address translation mechanism is not used. The contents of the EPLC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

EPLC_{EPR} is used in place of MSR_{PR}
 EPLC_{EAS} is used in place of MSR_{DS}
 EPLC_{EPID} is used in place of PID
 EPLC_{EGS} is used in place of MSR[GS] <E.HV>
 EPLC_{ELPID} is used in place of LPIDR <E.HV>

Special Registers Altered:

None

Extended Mnemonics:

Extended mnemonics are provided for the *Data Cache Block Touch by External PID* instruction so that it can

be coded with the TH value as the last operand for all categories. .

Extended: dcbtctep RA, RB, TH
Equivalent to: dcbtctep for TH values of 0b0000 - 0b0111;
 other TH values are invalid.

dcbtdsep RA, RB, TH
Equivalent to: dcbtctep for TH values of 0b0000 or 0b1000 - 0b1010;
 other TH values are invalid.

Programming Note

This instruction behaves identically to a *dcbt* instruction except for using the EPLC register to provide the translation context, and not supporting the Stream category.

Data Cache Block Flush by External PID X-form

dcbfep RA, RB

0	31	6	///	11	RA	16	RB	21	127	31
---	----	---	-----	----	----	----	----	----	-----	----

Let the effective address (EA) be the sum (RA10)+(RB).

If the block containing the byte addressed by EA is in storage that is Memory Coherence Required, a block containing the byte addressed by EA is in the data cache of any thread, and any locations in the block are considered to be modified there, then those locations are written to main storage. Additional locations in the block may also be written to main storage. The block is invalidated in the data cache of all threads.

If the block containing the byte addressed by EA is in storage that is not Memory Coherence Required, a block containing the byte addressed by EA is in the data cache of this thread, and any locations in the block are considered to be modified there, then those locations are written to main storage. Additional locations in the block may also be written to main storage. The block is invalidated in the data cache of this thread.

The function of this instruction is independent of whether the block containing the byte addressed by EA is in storage that is Write Through Required or Caching Inhibited.

The instruction is treated as a *Load* with respect to translation, memory protection, and is treated as a *Write* with respect to debug events.

This instruction is privileged.

The normal translation mechanism is not used. The contents of the EPLC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

EPLC_{EPR} is used in place of MSR_{PR}
 EPLC_{EAS} is used in place of MSR_{DS}
 EPLC_{EPID} is used in place of PID
 EPLC_{EGS} is used in place of MSR[GS] <E.HV>
 EPLC_{ELPID} is used in place of LPIDR <E.HV>

Special Registers Altered:

None

Programming Note

This instruction behaves identically to a *dcbf* instruction except for using the EPLC register to provide the translation context.

Data Cache Block Touch for Store by External PID *X-form*

dcbtstep TH,RA,RB

0	31	TH	RA	RB	255		31
	6	11	16	21			

Let the effective address (EA) be the sum (RA10)+(RB).

The **dcbtstep** instruction provides a hint that the program will probably soon store to the block containing the byte addressed by EA. If the Cache Specification category is supported, the nature of the hint is affected by TH values of 0b00000 to 0b00111. Values associated with the Stream category are ignored. See Section 4.3.2 of Book II for more information.

If the block is in a storage location that is Caching Inhibited or Guarded, the hint is ignored.

The only operation that is “caused” by the **dcbtstep** instruction is the providing of the hint. The actions (if any) taken in response to the hint are not considered to be “caused by” or “associated with” the **dcbtstep** instruction (e.g., **dcbtstep** is considered not to cause any data accesses). No means are provided by which software can synchronize these actions with the execution of the instruction stream. For example, these actions are not ordered by the memory barrier created by a **sync** instruction.

The **dcbtstep** instruction may complete before the operation it causes has been performed.

The instruction is treated as a *Store*, except that no interrupt occurs if a protection violation occurs.

The instruction is privileged.

The normal address translation mechanism is not used. The contents of the EPLC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

EPLC_{EPR} is used in place of MSR_{PR}
 EPLC_{EAS} is used in place of MSR_{DS}
 EPLC_{EPID} is used in place of PID
 EPLC_{EGS} is used in place of MSR[GS] <E.HV>
 EPLC_{ELPID} is used in place of LPIDR <E.HV>

Special Registers Altered:

None

Extended Mnemonics:

Extended mnemonics are provided for the *Data Cache Block Touch for Store by External PID* instruction so

that it can be coded with the TH value as the last operand for all categories. .

Extended: dcbtstctep RA,RB,TH
Equivalent to: dcbtstep for TH values of 0b0000 - 0b0111; other TH values are invalid.

Programming Note

This instruction behaves identically to a **dcbtst** instruction except for using the EPLC register to provide the translation context, and not supporting the Stream category.

Instruction Cache Block Invalidate by External PID X-form

icbiep RA,RB

Let the effective address (EA) be the sum (RAI0)+(RB).

If the block containing the byte addressed by EA is in storage that is Memory Coherence Required and a block containing the byte addressed by EA is in the instruction cache of any thread, the block is invalidated in those instruction caches.

If the block containing the byte addressed by EA is in storage that is not Memory Coherence Required and a block containing the byte addressed by EA is in the instruction cache of this thread, the block is invalidated in that instruction cache.

The function of this instruction is independent of whether the block containing the byte addressed by EA is in storage that is Write Through Required or Caching Inhibited.

The instruction is treated as a *Load*.

This instruction is privileged.

For *icbiep*, the normal translation mechanism is not used. The contents of the EPLC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

EPLC_{EPR} is used in place of MSR_{PR}
 EPLC_{EAS} is used in place of MSR_{DS}
 EPLC_{EPID} is used in place of PID
 EPLC_{EGS} is used in place of MSR[GS] <E.HV>
 EPLC_{ELPID} is used in place of LPIDR <E.HV>

Special Registers Altered:

None

Programming Note

This instruction behaves identically to an *icbi* instruction except for using the EPLC register to provide the translation context.

Data Cache Block set to Zero by External PID X-form

dcbzep RA,RB

```

if RA = 0 then b ← 0
else          b ← (RA)
EA ← b + (RB)
n ← block size (bytes)
m ← log2(n)
ea ← EA0:63-m || m0
MEM(ea, n) ← n0x00
  
```

Let the effective address (EA) be the sum (RAI0)+(RB).

All bytes in the block containing the byte addressed by EA are set to zero.

This instruction is treated as a *Store*.

This instruction is privileged.

The normal translation mechanism is not used. The contents of the EPSC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

EPSC_{EPR} is used in place of MSR_{PR}
 EPSC_{EAS} is used in place of MSR_{DS}
 EPSC_{EPID} is used in place of PID
 EPSC_{EGS} is used in place of MSR[GS] <E.HV>
 EPSC_{ELPID} is used in place of LPIDR <E.HV>

Special Registers Altered:

None

Programming Note

See the Programming Notes for the *dcbz* instruction.

Programming Note

This instruction behaves identically to a *dcbz* instruction except for using the EPSC register to provide the translation context.

Load Floating-Point Double by External Process ID Indexed X-form

lfdex FRT,RA,RB

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
FRT ← MEM(EA, 8)

```

Let the effective address (EA) be the sum (RA)0+(RB). The doubleword in storage addressed by EA is loaded into FRT.

For **lfdex**, the normal translation mechanism is not used. The contents of the EPLC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

- EPLC_{EPR} is used in place of MSR_{PR}
- EPLC_{EAS} is used in place of MSR_{DS}
- EPLC_{EPID} is used in place of PID
- EPLC_{EGS} is used in place of MSR[GS] <E.HV>
- EPLC_{ELPID} is used in place of LPIDR <E.HV>

This instruction is privileged.

An attempt to execute **lfdex** while MSR_{FP}=0 will cause a Floating-Point Unavailable interrupt.

Corequisite Categories:
Floating-Point

Special Registers Altered:
None

Programming Note

This instruction behaves identically to a **lfdx** instruction except for using the EPLC register to provide the translation context.

Store Floating-Point Double by External Process ID Indexed X-form

stfdex FRS,RA,RB

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
MEM(EA, 8) ← (FRS)

```

Let the effective address (EA) be the sum (RA)0+(RB). (FRS) is stored into the doubleword in storage addressed by EA.

For **stfdex**, the normal translation mechanism is not used. The contents of the EPSC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

- EPSC_{EPR} is used in place of MSR_{PR}
- EPSC_{EAS} is used in place of MSR_{DS}
- EPSC_{EPID} is used in place of PID
- EPSC_{EGS} is used in place of MSR[GS] <E.HV>
- EPSC_{ELPID} is used in place of LPIDR <E.HV>

This instruction is privileged.

An attempt to execute **stfdex** while MSR_{FP}=0 will cause a Floating-Point Unavailable interrupt.

Corequisite Categories:
Floating-Point

Special Registers Altered:
None

Programming Note

This instruction behaves identically to a **stfdx** instruction except for using the EPSC register to provide the translation context.

Vector Load Doubleword into Doubleword by External Process ID Indexed EVX-form

evlddpx RT,RA,RB

0	31	RT	RA	RB	799	/	31
	6	11	16	21			

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
RT ← MEM(EA, 8)

```

Let the effective address (EA) be the sum (RAI0)+(RB). The doubleword in storage addressed by EA is loaded into RT.

For *evlddpx*, the normal translation mechanism is not used. The contents of the EPLC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

EPLC_{EPR} is used in place of MSR_{PR}
 EPLC_{EAS} is used in place of MSR_{DS}
 EPLC_{EPIID} is used in place of PID
 EPLC_{EGS} is used in place of MSR[GS] <E.HV>
 EPLC_{ELPID} is used in place of LPIDR <E.HV>

This instruction is privileged.

An attempt to execute *evlddpx* while MSR_{SPV}=0 will cause an SPE Unavailable interrupt.

Corequisite Categories:

Signal Processing Engine

Special Registers Altered:

None

Programming Note

This instruction behaves identically to a *evlddx* instruction except for using the EPLC register to provide the translation context.

Vector Store Doubleword into Doubleword by External Process ID Indexed EVX-form

evstddpx RS,RA,RB

0	31	RT	RA	RB	927	/	31
	6	11	16	21			

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
MEM(EA, 8) ← (RS)

```

Let the effective address (EA) be the sum (RAI0)+(RB). (RS) is stored into the doubleword in storage addressed by EA.

For *evstddpx*, the normal translation mechanism is not used. The contents of the EPSC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

EPSC_{EPR} is used in place of MSR_{PR}
 EPSC_{EAS} is used in place of MSR_{DS}
 EPSC_{EPIID} is used in place of PID
 EPSC_{EGS} is used in place of MSR[GS] <E.HV>
 EPSC_{ELPID} is used in place of LPIDR <E.HV>

This instruction is privileged.

An attempt to execute *evstddpx* while MSR_{SPV}=0 will cause an SPE Unavailable interrupt.

Corequisite Categories:

Signal Processing Engine

Special Registers Altered:

None

Programming Note

This instruction behaves identically to a *evstddx* instruction except for using the EPSC register to provide the translation context.

Load Vector by External Process ID Indexed X-form

lvepx VRT,RA,RB

0	31	VRT	RA	RB	295	/	31
	6	11	16	21			

```
if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
VRT ← MEM(EA & 0xFFFF_FFFF_FFFF_FFF0, 16)
```

Let the effective address (EA) be the sum (RA10)+(RB). The quadword in storage addressed by the result of EA ANDed with 0xFFFF_FFFF_FFFF_FFF0 is loaded into VRT.

For *lvepx*, the normal translation mechanism is not used. The contents of the EPLC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

- EPLC_{EPR} is used in place of MSR_{PR}
- EPLC_{EAS} is used in place of MSR_{DS}
- EPLC_{EPIID} is used in place of PID
- EPLC_{EGS} is used in place of MSR[GS] <E.HV>
- EPLC_{ELPID} is used in place of LPIDR <E.HV>

This instruction is privileged.

An attempt to execute *lvepx* while MSR_{SPV}=0 will cause a Vector Unavailable interrupt.

Corequisite Categories:

Vector

Special Registers Altered:

None

Programming Note

This instruction behaves identically to a *lvx* instruction except for using the EPLC register to provide the translation context.

Load Vector by External Process ID Indexed LRU X-form

lvepxl VRT,RA,RB

0	31	VRT	RA	RB	263	/	31
	6	11	16	21			

```
if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
VRT ← MEM(EA & 0xFFFF_FFFF_FFFF_FFF0, 16)
mark_as_not_likely_to_be_needed_again_anytime_soon
( EA )
```

Let the effective address (EA) be the sum (RA10)+(RB). The quadword in storage addressed by the result of EA ANDed with 0xFFFF_FFFF_FFFF_FFF0 is loaded into VRT.

lvepxl provides a hint that the quadword in storage addressed by EA will probably not be needed again by the program in the near future.

For *lvepxl*, the normal translation mechanism is not used. The contents of the EPLC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

- EPLC_{EPR} is used in place of MSR_{PR}
- EPLC_{EAS} is used in place of MSR_{DS}
- EPLC_{EPIID} is used in place of PID
- EPLC_{EGS} is used in place of MSR[GS] <E.HV>
- EPLC_{ELPID} is used in place of LPIDR <E.HV>

This instruction is privileged.

An attempt to execute *lvepxl* while MSR_{SPV}=0 will cause a Vector Unavailable interrupt.

Corequisite Categories:

Vector

Special Registers Altered:

None

Programming Note

See the Programming Notes for the *lvxl* instruction in Section 6.7.2 of Book I.

Programming Note

This instruction behaves identically to a *lvxl* instruction except for using the EPLC register to provide the translation context.

Store Vector by External Process ID Indexed *X*-form

stvepx VRS,RA,RB

```
if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
MEM(EA & 0xFFFF_FFFF_FFFF_FFF0, 16) ← (VRS)
```

Let the effective address (EA) be the sum (RAI0)+(RB). The contents of VRS are stored into the quadword in storage addressed by the result of EA ANDed with 0xFFFF_FFFF_FFFF_FFF0.

For *stvepx*, the normal translation mechanism is not used. The contents of the EPSC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

- EPSC_{EPR} is used in place of MSR_{PR}
- EPSC_{EAS} is used in place of MSR_{DS}
- EPSC_{EPIID} is used in place of PID
- EPSC_{EGS} is used in place of MSR[GS] <E.HV>
- EPSC_{ELPID} is used in place of LPIDR <E.HV>

This instruction is privileged.

An attempt to execute *stvepx* while MSR_{SPV}=0 will cause a Vector Unavailable interrupt.

Corequisite Categories:

Vector

Special Registers Altered:

None

Programming Note

This instruction behaves identically to a *stvx* instruction except for using the EPSC register to provide the translation context.

Store Vector by External Process ID Indexed LRU *X*-form

stvepxl VRS,RA,RB

```
if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
MEM(EA & 0xFFFF_FFFF_FFFF_FFF0, 16) ← (VRS)
mark_as_not_likely_to_be_needed_again_anytime_soon
(EA)
```

Let the effective address (EA) be the sum (RAI0)+(RB). The contents of VRS are stored into the quadword in storage addressed by the result of EA ANDed with 0xFFFF_FFFF_FFFF_FFF0.

The *stvepxl* instruction provides a hint that the quadword addressed by EA will probably not be needed again by the program in the near future.

For *stvepxl*, the normal translation mechanism is not used. The contents of the EPSC register are used to provide the context in which translation occurs. The following substitutions are made for just the translation and access control process:

- EPSC_{EPR} is used in place of MSR_{PR}
- EPSC_{EAS} is used in place of MSR_{DS}
- EPSC_{EPIID} is used in place of PID
- EPSC_{EGS} is used in place of MSR[GS] <E.HV>
- EPSC_{ELPID} is used in place of LPIDR <E.HV>

This instruction is privileged.

An attempt to execute *stvepxl* while MSR_{SPV}=0 will cause a Vector Unavailable interrupt.

Corequisite Categories:

Vector

Special Registers Altered:

None

Programming Note

See the Programming Notes for the *lvxl* instruction in Section 6.7.2 of Book I.

Programming Note

This instruction behaves identically to a *stvxl* instruction except for using the EPSC register to provide the translation context.

6.1 Overview

Instruction effective addresses are generated for sequential instruction fetches and for addresses that correspond to a change in program flow (branches, interrupts). Data effective addresses are generated by *Load*, *Store*, and *Cache Management* instructions. *TLB Management* instructions generate effective addresses to determine the presence of or to invalidate a specific TLB entry associated with that address. For a complete discussion of storage addressing and effective address calculation, see Section 1.10 of Book I.

Portions of the context of an effective address are appended to it to form the virtual address. The context is provided by various registers. The virtual address consists of the Logical Partition ID (LPID) <E.HV>, the Guest State <E.HV>, the address space identifier, the process identifier, and the effective address. The virtual address is translated to a real address by a matching “direct” entry in the Translation Lookaside Buffer (TLB) according to procedures described in Section 6.7.3. The Virtual Page Number (VPN) part of the virtual address is compared to the TLB contents to determine a match. The VPN consists of bits of the virtual address with the exception of the low-order effective address bits that correspond to the byte offset within the page. If the Embedded.Page Table category is supported, a virtual address can be translated by the Page Table pointed to by a matching “indirect” TLB entry as described in Section 6.7.4. As a result of a Page Table translation, a direct TLB entry is created, and this direct TLB entry can be used for subsequent translations. All virtual addresses are translated by the Page Table <E.PT> or the TLB, i.e. unlike the Server environment, there is no real mode. The real address that results from the translation is used to access main storage.

The Translation Lookaside Buffer is the hardware resource that also controls protection and storage control attributes. TLB permission bits control user and supervisor read, write and execute capability. If the Embedded.Hypervisor category is supported, the Virtualization Fault bit permits data accesses to pages to be

trapped to the hypervisor, which allows the hypervisor to virtualize data accesses to specific pages, e.g. accesses to memory-mapped I/O. Storage control attributes described in Book II are supported by corresponding TLB bits, as are four optional implementation-dependent user-defined storage control attributes. The organization of the TLB (e.g. associativity, number of entries, number of arrays, etc.) is implementation-dependent. There is MMU configuration and TLB configuration information in various registers to describe this implementation-dependent organization.

Software manages translation directly by installing TLB entries, and indirectly by setting up the page tables, which the TLB will cache. *TLB Management* instructions are used by software to read, write, search and invalidate TLB contents. MMU Assist Registers (MAS) are used to transfer data to and from the TLB arrays by *TLB Management* instructions. If the Embedded.Hypervisor category is not supported, *TLB Management* instructions are privileged instructions.

A different MMU Architecture Version (MAV) is used to indicate that different register layouts and functions are provided. The MMU Architecture Version Number is specified by the read-only MMUCFG register. The Embedded.Hypervisor.LRAT, Embedded TLB Write Conditional, and Embedded.Page Table categories are available only in MMU Architecture Version 2.0.

If the Embedded.Hypervisor category is supported and the Embedded.Hypervisor.LRAT category is not supported, most *TLB Management* instructions are hypervisor instructions. TLB entries contain real addresses, and, to maintain isolation between partitions, guest operating systems are not given access to real addresses. In this case most *TLB Management* instructions trap to the hypervisor. The hypervisor can emulate a *TLB Management* instruction by swapping a Real Page Number for corresponding Logical Page Number (LPN) in the MAS registers or vice versa so that the guest OS only sees LPNs.

However, if the Embedded.Hypervisor.LRAT category is supported, hardware can perform the translation of

an LPN into a corresponding RPN. In this case, a *TLB Write Entry (tlbwe)* instruction can be executed in guest supervisor state. The LPN in the MAS register is translated into a corresponding RPN by a hardware lookup in a Logical to Real Address Translation (LRAT) array, and the RPN is written to the TLB in place of the LPN when *tlbwe* is executed in guest supervisor state.

The Embedded.TLB Write Conditional (E.TWC) category provides a TLB write operation that is conditional on a TLB-reservation where the TLB-reservation is previously established by a *tlbsrx* instruction. The TLB-reservation is cleared by TLB invalidations and TLB writes involving the same virtual page. Thus, without acquiring a software lock, software can use the E.TWC category to write a TLB entry while ensuring that the entry is not a duplicate of an entry created simultaneously by another thread that shares the TLB and is not a stale value for a virtual page that was concurrently invalidated.

Figure 18 gives an overview of address translation if the Embedded.Page Table category is supported. The IND bit in a TLB entry indicates whether the entry is a “direct” entry or “indirect” entry. When a virtual address is translated, the TLB arrays are searched for a matching entry. If there is one and only one matching direct entry, that entry is used to translate the VA. If there is no matching direct TLB entry, but there is one and only one matching indirect entry, the indirect entry is used to access a Page Table Entry (PTE). If the PTE is a valid entry (V bit = 1), the PTE is used to translate the address. If the Embedded.Page Table and Embedded.Hypervisor categories are both supported, the Embedded.Hypervisor.LRAT category is supported. In this case if the TGS bit of the indirect TLB entry is 1, the RPN from the PTE is treated as a Logical Page Number (LPN) and translated by the LRAT into an RPN. If the Embedded.Page Table is supported but the Embedded.Hypervisor category is not supported, supervisor software can create direct and indirect TLB entries and can control the Page Table Entries. If both categories are supported, guest supervisor software can still create direct and indirect TLB entries and control the Page Table Entries if guest execution of *TLB Management* instructions is enabled. However, depending on various factors such as the number of available LRAT entries, performance may be better if guest virtual addresses are translated by a Page Table that is managed by hypervisor software.

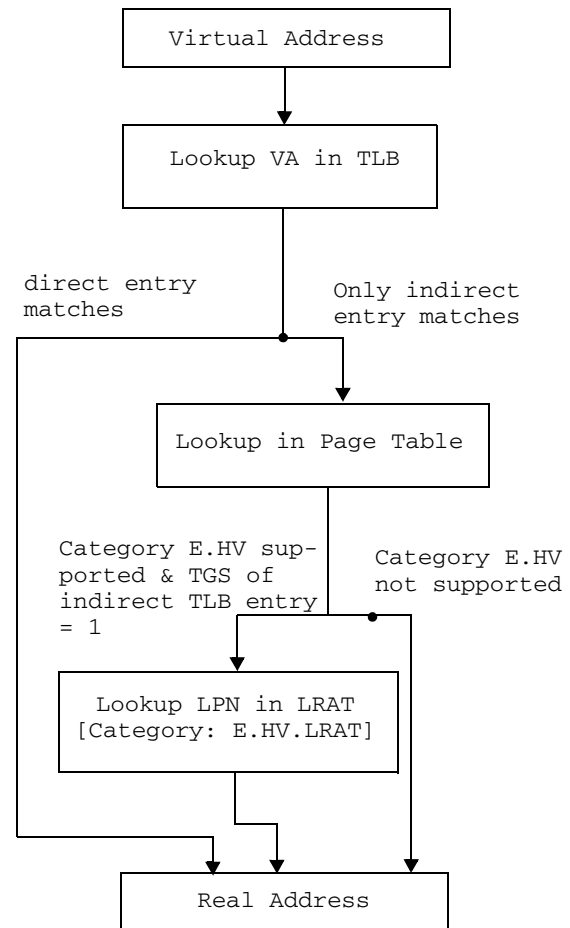

Figure 18. Address translation with page table

Address Size Overview

- Real address space size is 2^m bytes, $m \leq 64$; see Note 1.
- In MMU Architecture Version 1.0, real page sizes are 4^p KB where $0 \leq p \leq 15$ (i.e. 1 KB, 4KB, 16KB, 64KB, 256KB, 1MB, 4MB, 16MB, 64MB, 256MB, 1GB, 4GB, 16GB, 64GB, 256GB, 1TB); see Note 2. In MMU Architecture Version 2.0, real page sizes are 2^p KB where $0 \leq p \leq 31$ (i.e. 1 KB, 2 KB, 4KB, 8 KB, 16KB, 32KB, 64KB, 128KB, 256KB, 512KB, 1MB, 2MB, 4MB, 8MB, 16MB, 32MB, 64MB, 128MB, 256MB, 512MB, 1GB, 2GB, 4GB, 8GB, 16GB, 32GB, 64GB, 128GB, 256GB, 512GB, 1TB, 2TB); see Note 2. However, real pages sizes supported by a Page Table are limited to values of p where $2 \leq p \leq 15$.
- Effective address space size is 2^{64} bytes in 64-bit implementations and 2^{32} bytes in 32-bit implementations.
- The virtual address space size depends on the implementation.

- Virtual address space size in 64-bit implementations is 2^v bytes, where:
 - $66 \leq v \leq 79$ if the Embedded.Hypervisor Category is not supported; see Note 3.
 - $68 \leq v \leq 92$ if the Embedded.Hypervisor Category is supported; see Note 3.
- Virtual address space size in 32-bit implementations is 2^v bytes, where:
 - $34 \leq v \leq 47$ if the Embedded.Hypervisor Category is not supported; see Note 3.
 - $36 \leq v \leq 60$ if the Embedded.Hypervisor Category is supported; see Note 3.
- The number of LPID <E.HV> bits is $1 \leq g \leq 12$; see Note 3.
- There is one GS <E.HV> bit.
- There is one AS bit.
- The number of PID bits is $1 \leq d \leq 14$; see Note 3.
- For any given real page, the virtual page size is the same as the real page size.
- If the Embedded.Hypervisor.LRAT category is supported, the following applies.
 - The logical page sizes allowed by the architecture are the same as the real page sizes. However, an implementation need not support the same logical and real page sizes.
 - The logical address space size is 2^q bytes, where $q \leq 64$; see Note 4.

Notes:

1. The value of m is implementation-dependent (subject to the maximum given above). When used to address storage, the high-order 64- m bits of the “64-bit” real address must be zeros. A maximum of 64 bits of real address can be supported by the TLB. A maximum of 52 bits of real address can be supported by the Page Table <E.PT>.
2. Which of these page sizes are supported is implementation-dependent. If an implementation supports multiple TLB arrays, the page sizes supported by each array may be different. Supported page sizes are indicated by TLB configuration information (see Sections 6.10.3.3 and 6.10.3.4).
3. The values of v , g , and d are implementation-dependent (subject to the range given above). The value of v is a function of g , d , whether the implementation is 32-bit or 64-bit, and whether the Embedded.Hypervisor category is supported.
4. The value of q is implementation-dependent (subject to the maximum given above). A maximum of 64 bits of logical address can be supported by the LRAT. A maximum of 52 bits of logical address can be supported by the Page Table <E.PT>.

Programming Note

[Category: Embedded.Hypervisor.LRAT]: The logical page sizes supported by an implementation are typically larger than the real page sizes supported. This implies that memory blocks must be assigned to a partition with larger granularity than the memory blocks that can be managed within a partition.

6.2 Storage Exceptions

A *storage exception* results when the sequential execution model requires that a storage access be performed but the access is not permitted (e.g., is not permitted by the storage protection mechanism), the access cannot be performed because the effective address cannot be translated to a real address, or the access matches some tracking mechanism criteria (e.g., Data Address Breakpoint).

In certain cases a storage exception may result in the “restart” of (re-execution of at least part of) a Load or Store instruction. See Section 2.1 of Book II and Section 7.7 on page 1054 in this Book.

6.3 Instruction Fetch

For an instruction fetch, MSR_{IS} is appended to the effective address as part of the virtual address. The Address Translation mechanism is described in Section 6.7.2, Section 6.7.3, and, if the Embedded.Page Table category is supported, Section 6.7.4.

6.3.1 Implicit Branch

Explicitly altering certain MSR bits (using *mtmsr*), or explicitly altering TLB entries, certain System Registers and possibly other implementation-dependent registers, may have the side effect of changing the addresses, effective or real, from which the current instruction stream is being fetched. This side effect is called an *implicit branch*. For example, an *mtmsr* instruction that changes the value of MSR_{CM} may change the real address from which the current instruction stream is being fetched. The MSR bits and System Registers (excluding implementation-dependent registers) for which alteration can cause an implicit branch are indicated as such in Chapter 12. “Synchronization Requirements for Context Alterations” on page 1099. Implicit branches are not supported by the Power ISA. If an implicit branch occurs, the results are boundedly undefined.

6.3.2 Address Wrapping Combined with Changing MSR Bit CM

If the current instruction is at effective address 2^{32-4} and is an *mtmsr* instruction that changes the contents of MSR_{CM} , the effective address of the next sequential instruction is undefined.

Programming Note

In the case described in the preceding paragraph, if an interrupt occurs before the next sequential instruction is executed, the contents of $SRR0$, $CSRR0$, or $MCSRR0$, as appropriate to the interrupt, are undefined if the *Embedded.Hypervisor* category is not supported or the interrupt is directed to the hypervisor state. If the *Embedded.Hypervisor* category is supported and the interrupt is directed to the guest state, the contents of $GSRR0$ are undefined.

6.4 Data Access

For a normal *Load* or *Store* instruction, MSR_{DS} is appended to the effective address as part of the virtual address. The Address Translation mechanism is described in Section 6.7.2, Section 6.7.3, and, if the *Embedded.Page Table* category is supported, Section 6.7.4. The *Embedded.External PID* category must be supported. The effective address for an *External Process ID Load* or *Store* instruction data access is processed under control of the *EPLC* or *EPSC*, respectively. See Section 5.3.6.1 and Section 5.3.6.2.

6.5 Performing Operations Out-of-Order

An operation is said to be performed “in-order” if, at the time that it is performed, it is known to be required by the sequential execution model. An operation is said to be performed “out-of-order” if, at the time that it is performed, it is not known to be required by the sequential execution model.

Operations are performed out-of-order on the expectation that the results will be needed by an instruction that will be required by the sequential execution model. Whether the results are really needed is contingent on everything that might divert the control flow away from the instruction, such as *Branch*, *Trap*, *System Call*, and *Return From Interrupt* instructions, and interrupts, and on everything that might change the context in which the instruction is executed.

Typically, operations are performed out-of-order when resources are available that would otherwise be idle, so the operation incurs little or no cost. If subsequent events such as branches or interrupts indicate that the

operation would not have been performed in the sequential execution model, any results of the operation are abandoned (except as described below).

In the remainder of this section, including its subsections, “*Load* instruction” includes the *Cache Management* and other instructions that are stated in the instruction descriptions to be “treated as a *Load*”, and similarly for “*Store* instruction”.

A data access that is performed out-of-order may correspond to an arbitrary *Load* or *Store* instruction (e.g., a *Load* or *Store* instruction that is not in the instruction stream being executed). Similarly, an instruction fetch that is performed out-of-order may be for an arbitrary instruction (e.g., the aligned word at an arbitrary location in instruction storage).

Most operations can be performed out-of-order, as long as the machine appears to follow the sequential execution model. Certain out-of-order operations are restricted, as follows.

■ Stores

Stores are not performed out-of-order (even if the *Store* instructions that caused them were executed out-of-order).

■ Accessing Guarded Storage

The restrictions for this case are given in Section 6.8.1.1.

The only permitted side effects of performing an operation out-of-order are the following.

■ A Machine Check that could be caused by in-order execution may occur out-of-order except that, if category *E.HV* is supported and the Machine Check is the result of multiple TLB entries that translate the same VA, the Machine Check interrupt must occur in the context in which it was caused. Also, if category *E.HV* is supported, a Machine Check interrupt resulting from the following situations must be precise.

- Execution of an *External Process ID* instruction that has an operand that can be translated by multiple TLB entries.

- Execution of a *tlbivax* instruction that isn't a TLB invalidate all and there are multiple entries in a single thread's TLB array(s) that match the complete VPN.

- Execution of a *tlbilx* instruction with $T=3$ and there are multiple entries in the TLB array(s) that match the complete VPN.

- Execution of a *tlbsx* or *tlbsrx* instruction and there are multiple matching TLB entries.

■ Non-Guarded storage locations that could be fetched into a cache by in-order fetching or execution of an arbitrary instruction may be fetched out-of-order into that cache.

6.6 Invalid Real Address

A storage access (including an access that is performed out-of-order; see Section 6.5) may cause a Machine Check if the accessed storage location contains an uncorrectable error or does not exist. See Section 7.6.3 on page 1034.

6.7 Storage Control

This section describes the address translation facility, access control, and storage control attributes.

Demand-paged virtual memory is supported, as well as a variety of other management schemes that depend on precise control of effective-to-real address translation and flexible memory protection. Translation misses and protection faults cause precise exceptions. Sufficient information is available to correct the fault and restart the faulting instruction.

The effective address space is divided into pages. The page represents the granularity of effective address translation, access control, and storage control attributes. In MMU Architecture Version 1.0, up to sixteen page sizes (1KB, 4KB, 16KB, 64KB, 256KB, 1MB, 4MB, 16MB, 64MB, 256MB, 1GB, 4GB, 16GB, 64GB, 256GB, 1TB) may be simultaneously supported. In MMU Architecture Version 2.0, up to 32 page sizes (1 KB, 2 KB, 4KB, 8 KB, 16KB, 32KB, 64KB, 128KB, 256KB, 512KB, 1MB, 2MB, 4MB, 8MB, 16MB, 32MB, 64MB, 128MB, 256MB, 512MB, 1GB, 2GB, 4GB, 8GB, 16GB, 32GB, 64GB, 128GB, 256GB, 512GB, 1TB, 2TB) may be simultaneously supported. In order for an effective to real translation to exist, a valid entry for the page containing the effective address must be in the Translation Lookaside Buffer (TLB). Addresses for which no TLB entry exists cause TLB Miss exceptions.

6.7.1 Translation Lookaside Buffer

The Translation Lookaside Buffer (TLB) is the hardware resource that controls translation, protection, and storage control attributes. The organization of the TLB (e.g. associativity, number of entries, number of arrays, etc.) is implementation-dependent. Thus, the software for updating the TLB is also implementation-dependent. However, MMU configuration and TLB configuration information is provided such that software written to handle various TLB organizations could potentially run on multiple MMU implementations. A unified TLB organization (one to four TLB arrays, called TLB0, TLB1, TLB2 and TLB3, where each contains translations for both instructions and data) is assumed in the following description. For details on how to synchronize TLB updates with instruction execution see Section 6.11.4.3 and Chapter 12.

Maintenance of TLB entries is under software control, except that if the Embedded.Page Table category is supported, hardware will write TLB entries for translations performed via the Page Table. System software determines TLB entry replacement strategy and the format and use of any page state information. If a TLB provides Next Victim (NV) information, software can optionally use NV to choose a TLB entry to be replaced. See Section 6.11.4.7. Some implementations allow software to specify that a hardware generated hash and hardware replacement algorithm should be used to select the entry. See Section 6.11.4.7. The TLB entry contains all the information required to identify the page, to specify the translation, to specify access controls, and to specify the storage control attributes.

A TLB entry is written by copying information from MAS registers, using a *tlbwe* instruction (see page 1010). A TLB entry is read by copying information to MAS registers, using a *tlbre* instruction (see page 1008). Software can also search for specific TLB entries using the *tlbsx* instruction (see page 1005) and, if the Embedded.TLB Write Conditional category is supported, *tlbsrx*. (see page 1007).

Each TLB entry describes a page. Fields in the TLB entry fall into five categories:

- Page identification fields (information required to identify the page to the hardware translation mechanism).
- Address translation fields
- Access control fields
- Storage control attribute fields
- TLB management field

While the fields in the TLB entry are required, unless they are identified as part of a category that is not supported, no particular TLB entry format is formally specified. The *tlbre* and *tlbwe* instructions provide the ability to read or write individual entries. Below are shown the field definitions for the TLB entry. Some fields that are used only for indirect TLB entries can be overlaid with fields that are used only for direct TLB entries. Such overlap is implementation-dependent and an example is shown in Figure 19 on page 949.

Page Identification Fields for direct and indirect entries

Name Description

EPN **Effective Page Number** (up to 54 bits)
Bits 0: $n-1$ of the EPN field are compared to bits 0: $n-1$ of the effective address (EA) of the storage access (where $n=64-\log_2(\text{page size in bytes})$ and *page size* is specified by the SIZE field of the TLB entry). See Table 2 and Table 3.

Note: Bits X:Y of the EPN field are implemented, where X=0 (64-bit implementation) or X=32 (32-bit implementation), and $Y \leq 53$. $Y = p - 1$ where $p = 64 - \log_2(\text{smallest page size in bytes})$ and *smallest page size* is the smallest page size supported by the implementation as specified by TLB array's TLBnCFG or TLBnPS. The number of bits implemented for EPN is not required to be the same number of bits as are implemented for RPN. Implemented bits that represent offsets within a page are ignored for address comparisons performed for translation, invalidation, and searches and software should set these bits to zero. Unimplemented EPN bits are treated as if they contain 0s.

TS Translation Address Space

This bit indicates the address space this TLB entry is associated with. For instruction storage accesses, MSR_{IS} must match the value of TS in the TLB entry for that TLB entry to provide the translation. Likewise, for data storage accesses, MSR_{DS} must match the value of TS in the TLB entry. For the *tlbsrx* <E.TWC> instruction, MAS1_{TS} provides the address space specification that must match the value of TS. For the *tlbsx* instruction, MAS6_{SAS} provides the address space specification that must match the value of TS. For the instructions *tlbilx* <E.HV> with T=3 and *tlbivax* with EA₆₁=0, MAS6_{SAS} provides the address space specification that is compared to the value of TS.

SIZE Page Size

For direct TLB entries, the SIZE field specifies the size of the virtual page associated with the TLB entry. For indirect TLB entries, the SIZE field specifies the maximum amount of virtual storage that can be mapped by the page table to which the indirect TLB entry points. The following applies in both cases:

- For MAV = 1.0, 4^{SIZE}KB , where $0 \leq \text{SIZE} \leq 15$. See Table 2. For TLB arrays that contain fixed-size TLB entries, this field is treated as reserved for *tlbwe* and *tlbre* instructions and is treated as a fixed value for translations. For variable page size TLB arrays, this field must be a value between TLBnCFG_{MIN}SIZE and TLBnCFG_{MAX}SIZE.
- For MAV = 2.0, 2^{SIZE}KB , where $0 \leq \text{SIZE} \leq 31$. See Table 3. This field must be one of the page sizes specified by the corresponding TLBnPS register.

Implementations may support any one or more of the page sizes described above.

TID Translation ID (implementation-dependent size)

Field used to identify a shared page (TID=0) or the owner's process ID of a private page (TID≠0). See Section 6.7.2.

TLPID Translation Logical Partition ID <E.HV>

This field identifies a partition. The Translation Logical Partition ID is compared with LPIDR contents during translation. This allows for an efficient change of address space when a transition between partitions occurs. This number of bits in this field is an implementation-dependent number n , where $1 \leq n \leq 12$. See Section 6.7.2.

TGS Translation Guest State <E.HV>

This 1-bit field indicates whether this TLB entry is valid for the guest space or for the hypervisor space. The Translation Guest Space field is compared with the MSR_{GS} bit during translation. This allows for an efficient change of address space when a transition from guest state to hypervisor state occurs. See Section 6.7.2.

0 Hypervisor space

1 Guest space

V	Valid This bit indicates whether that this TLB entry is valid and may be used for translation. The Valid bit for a given entry can be set or cleared with a <i>tlbwe</i> instruction; alternatively, the Valid bit for an entry may be cleared by a <i>tlbilx</i> <E.HV> or <i>tlbivax</i> instruction or by a MMUCSR0 TLB invalidate all.
IND	Indirect <E.PT> This bit distinguishes between an indirect TLB entry that points to a Page Table (IND=1) and a direct TLB entry that can be used directly to translate a virtual address (IND=0). If a TLB array does not support this bit (TLBnCFG _{IND} = 0), the implied IND value is 0. For the <i>tlbsx</i> instruction, MAS6 _{SIND} provides the direct/indirect specification that must match the value of IND. For the instructions <i>tlbilx</i> <E.HV> with T=3 and <i>tlbivax</i> with EA ₆₁ =0, MAS6 _{SIND} provides the direct/indirect specification that is compared to the value of IND. See Section 6.7.4.

Page Identification Field for indirect entry**Name Description**

SPSIZE	Sub-Page Size (IND=1) <E.PT> SPSIZE is a 5-bit field that specifies the minimum page size that can be specified by each Page Table Entry in the Page Table that is pointed to by the indirect TLB entry. This minimum page size is 2 ^{SPSIZE} KB and must be at least 4 KB. Thus SPSIZE must be at least 2. Valid values are specified by EPTCFG _{SPS2} SPS1 SPS0. See Section 6.7.4
--------	---

Translation Field**Name Description**

RPN	Real Page Number (up to 54 bits) For a direct TLB entry, bits 0:n-1 of the RPN field are used to replace bits 0:n-1 of the effective address to produce the real address for the storage access (where $n=64-\log_2(\text{page size in bytes})$ and <i>page size</i> is specified by the SIZE field of the TLB entry). See Section 6.7.3 for a requirement on unused low-order RPN bits (i.e. bits n:53) being 0. For an indirect TLB entry, bits 0:m-1 of the RPN field followed by 64-m 0s are the real address of the page table pointed to the indirect TLB entry, where $m = 61 - (\text{SIZE} - \text{SPSIZE})$. RPN bits m:53 must be zero. See Section 6.7.4. Note: Bits X:Y of the RPN field are implemented, where $X \geq 0$ and $Y \leq 53$. $X = 64 - \text{MMUCFG}_{\text{RASIZE}}$. Y is the larger of the following applicable values: <ul style="list-style-type: none"> ■ $p - 1$ where $p = 64 - \log_2(\text{smallest_page size in bytes})$ and <i>smallest page size</i> is the smallest page size supported by the implementation as specified by TLB array's TLBnCFG or TLBnPS. ■ 52 if the Embedded.Page Table category is supported and a page table size of 2 KB is supported (EPTCFG_{GPSn} - EPTCFG_{SPSn} = 8 for some value of n). The number of bits implemented for EPN is not required to be the same number of bits as are implemented for RPN. Unimplemented RPN bits are treated as if they contain 0s.

Storage Control Bits (see Section 6.8.3 on page 966)**Name Description**

W	Write-Through Required This bit indicates whether the page is Write-Through Required. See Section 1.6.1 of Book II. 0 This page is not Write-Through Required storage. 1 This page is Write-Through Required storage.
I	Caching Inhibited This bit indicates whether the page is Caching Inhibited. See Section 1.6.2 of Book II. 0 This page is not Caching Inhibited storage. 1 This page is Caching Inhibited storage.

M	<p>Memory Coherence Required This bit indicates whether the page is Memory Coherence Required. See Section 1.6.3 of Book II.</p> <p>0 This page is not Memory Coherence Required storage.</p> <p>1 This page is Memory Coherence Required storage.</p>	<p>Access Control Fields for direct TLB entry</p> <p>Name Description</p> <p>UX User State Execute Enable (IND=0) See Section 6.7.6.1.</p> <p>0 Instruction fetch and execution is not permitted from this page while $MSR_{PR}=1$ and will cause an Execute Access Control exception type Instruction Storage interrupt.</p> <p>1 Instruction fetch and execution is permitted from this page while $MSR_{PR}=1$.</p>
G	<p>Guarded This bit indicates whether the page is Guarded. See Section 1.6.4 of Book II and Section 6.8.1.</p> <p>0 This page is not Guarded storage.</p> <p>1 This page is Guarded storage.</p>	<p>SX Supervisor State Execute Enable (IND=0) See Section 6.7.6.1.</p> <p>0 Instruction fetch and execution is not permitted from this page while $MSR_{PR}=0$ and will cause an Execute Access Control exception type Instruction Storage interrupt.</p> <p>1 Instruction fetch and execution is permitted from this page while $MSR_{PR}=0$.</p>
E	<p>Endian Mode This bit indicates whether the page is accessed in Little-Endian or Big-Endian byte order. See Section 1.10.1 of Book I and Section 1.6.5 of Book II.</p> <p>0 The page is accessed in Big-Endian byte order.</p> <p>1 The page is accessed in Little-Endian byte order.</p>	<p>UW User State Write Enable (IND=0) See Section 6.7.6.2.</p> <p>0 <i>Store</i> operations, including <i>dcba</i>, <i>dcbz</i>, and <i>dcbzep</i> are not permitted to this page when $MSR_{PR}=1$ and will cause a Write Access Control exception. A Write Access Control exception will cause a Data Storage interrupt.</p> <p>1 <i>Store</i> operations, including <i>dcba</i>, <i>dcbz</i>, and <i>dcbzep</i> are permitted to this page when $MSR_{PR}=1$.</p>
U0:U3	<p>User-Definable Storage Control Attributes See Section 6.8.2.</p> <p>Specifies implementation-dependent and system-dependent storage control attributes for the page associated with the TLB entry. The existence of these bits is implementation-dependent.</p>	<p>SW Supervisor State Write Enable (IND=0) See Section 6.7.6.2.</p> <p>0 <i>Store</i> operations, including <i>dcba</i>, <i>dcbi</i>, <i>dcbz</i>, and <i>dcbzep</i> are not permitted to this page when $MSR_{PR}=0$. <i>Store</i> operations, including <i>dcbi</i>, <i>dcbz</i>, and <i>dcbzep</i>, will cause a Write Access Control exception. A Write Access Control exception will cause a Data Storage interrupt.</p> <p>1 <i>Store</i> operations, including <i>dcba</i>, <i>dcbi</i>, <i>dcbz</i>, and <i>dcbzep</i>, are permitted to this page when $MSR_{PR}=0$.</p>
VLE	<p>Variable Length Encoding <E.VLE> This bit specifies whether a page which contains instructions is to be decoded as VLE instructions (see Chapter 1 of Book VLE). See Section 6.8.3 and Chapter 1 of Book VLE.</p> <p>0 Instructions fetched from the page are decoded and executed as non-VLE instructions.</p> <p>1 Instructions fetched from the page are decoded and executed as VLE instructions.</p>	<p>UR User State Read Enable (IND=0) See Section 6.7.6.3.</p> <p>0 <i>Load</i> operations (including load-class <i>Cache Management</i> instructions) are not permitted from this page when $MSR_{PR}=1$ and will cause a Read Access Control exception. A Read Access Control exception will cause a Data Storage interrupt.</p> <p>1 <i>Load</i> operations (including load-class <i>Cache Management</i> instructions) are permitted from this page when $MSR_{PR}=1$.</p>
ACM	<p>Alternate Coherency Mode This bit allows an implementation to employ more than a single coherency method. This allows participation in multiple coherency protocols. If the M attribute (Memory Coherence Required) is not set for a page ($M=0$), the page has no coherency associated with it and the ACM attribute is ignored. If the M attribute is set to 1 for a page ($M=1$), the ACM attribute is used to determine the coherency domain (or protocol) used. The coherency method used in Alternate Coherency Mode is implementation-dependent.</p>	

- SR Supervisor State Read Enable** (IND=0)
See Section 6.7.6.3.
- 0 *Load* operations (including load-class *Cache Management* instructions) are not permitted from this page when $MSR_{PR}=0$ and will cause a Read Access Control exception. A Read Access Control exception will cause a Data Storage interrupt.
- 1 *Load* operations (including load-class *Cache Management* instructions) are permitted from this page when $MSR_{PR}=0$.

Access Control Field for direct and indirect entries

Name	Description
------	-------------

- | | |
|--|---------------------|
| VF Virtualization Fault <E.HV;E.PT> | See Section 6.7.6.4 |
|--|---------------------|
- This 1-bit field specifies whether the TLB entry is used by the hypervisor to virtualize data accesses, e.g. accesses to memory-mapped I/O. A translation of the operand address of a *Load*, *Store*, or *Cache Management* instruction that uses a TLB entry with the Virtualization Fault field equal to 1 causes a Virtualization Fault exception type Data Storage interrupt regardless of the settings of the permission bits. The interrupt is always directed to hypervisor state regardless of the setting of $EPCR_{DSIGS}$.
- 0 A *Load*, *Store*, or *Cache Management* access to this page does not cause a Virtualization Fault exception.
- 1 A *Load*, *Store*, or *Cache Management* access to this page causes a Virtualization Fault exception.

TLB Management Field

Name	Description
------	-------------

- | | |
|--------------------------------------|---|
| IPROT Invalidation Protection | A TLB entry with this bit equal to 1 is protected from all TLB invalidation mechanisms except the explicit writing of a 0 to the V bit. See Section 6.11.4.3. IPROT is implemented only for TLB entries in TLB arrays where $TLBnCFG_{IPROT}$ is indicated. If IPROT = 1, the TLB entry is protected from invalidate operations due to any of the following. <ul style="list-style-type: none"> ■ execution of <i>tlbivax</i> ■ execution of <i>tlbilx</i> <E.HV> ■ <i>tlbivax</i> invalidations from another thread ■ <i>tlbilx</i> <E.HV> invalidations from another thread when the TLB is shared with that thread ■ TLB invalidate all operations This bit is a hypervisor resource. |
|--------------------------------------|---|

Programming Note

Any TLB entry with $IPROT = 0$ is volatile and may be evicted for the following reasons even though software didn't explicitly remove or invalidate the entry.

- Generous TLB invalidations (*tlbivax* and *tlbilx*)
- TLB updates due to Page Table translations <E.PT>
- Hardware replacement algorithm on a *tlbwe* instruction if $MMUCFG_{HES}=1$ and $MAS0_{HES}=1$.

TLB entry with IND=0	TLB entry with IND=1
UX	$SPSIZE_0$
SX	$SPSIZE_1$
UW	$SPSIZE_2$
SW	$SPSIZE_3$
UR	$SPSIZE_4$
SR	RPN_{52}

Figure 19. Overlaid TLB Field Example

6.7.2 Virtual Address Spaces

There are two address spaces and their use is determined by the operating system. Some operating systems use one address space for user programs and one for certain supervisor software such as interrupt handlers. There are two bits in the Machine State Register, the Instruction Address Space bit (IS) and the Data Address Space bit (DS), that control which address space instruction and data storage accesses, respectively, are performed in, and a bit in the TLB entry (TS) that specifies which address space that TLB entry is associated with.

Programming Note

Because MSR_{IS} and MSR_{DS} are set to 0 by the hardware on interrupt, the Operating System software that handles interrupts should be designed to run with $AS=0$. As a result, Operating System software that wishes to, for example, use one address space for user and the other for supervisor should use $AS=0$ for supervisor and $AS=1$ for user.

If the Embedded.Hypervisor category is supported, the above two address spaces exist for each logical partition and for both the guest and non-guest states within each logical partition. The Logical Partition ID Register identifies the partition and a field in the TLB entry (TLPID) specifies which partition that TLB entry is associated with. The Guest State (GS) bit in the Machine State Register identifies the guest state or

non-guest state and a bit in the TLB entry (TGS) specifies which of these states that TLB entry is associated with.

Load, Store, Cache Management, and Branch instructions and next-sequential-instruction fetches produce a 64-bit effective address. A one-bit address space identifier and a process identifier are prepended to the effective address to form the virtual address. If the Embedded.Hypervisor category is supported, this address is also prepended by a Logical Partition ID and

Guest State bit. The Logical Partition ID is provided by the contents of LPIDR and the Guest State bit is provided by the MSR_{GS}. For instruction fetches, the address space identifier is provided by MSR_{IS} and the process identifier is provided by the contents of the Process ID Register. For data storage accesses, the address space identifier is provided by the MSR_{DS} and the process identifier is provided by the contents of the Process ID Register.

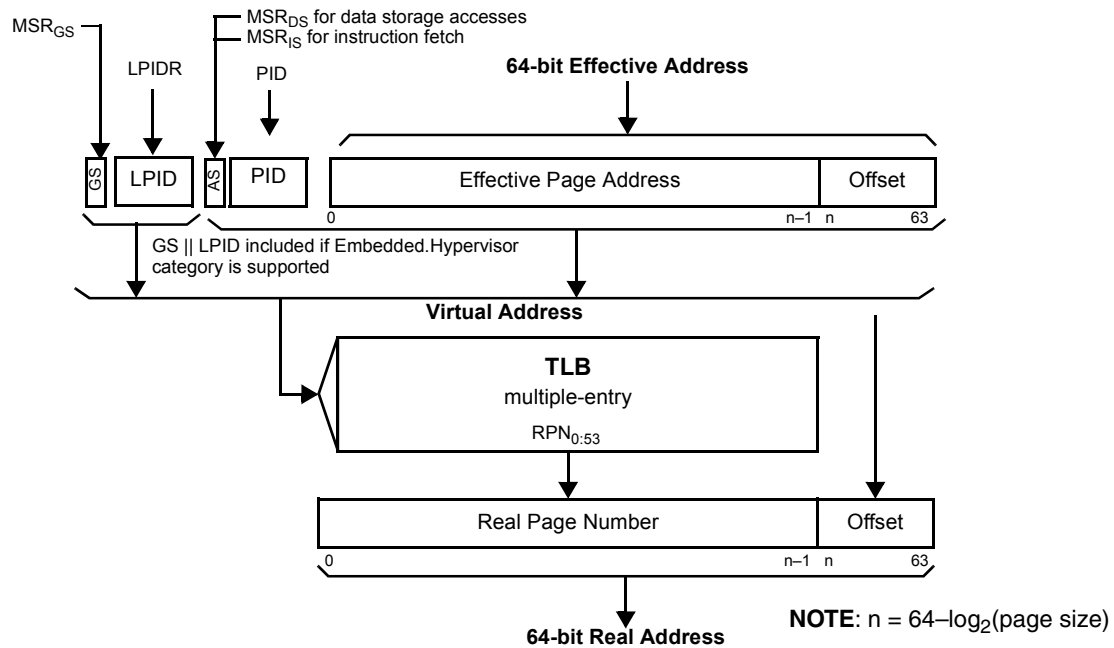

Figure 20. Effective-to-Virtual-to-Real TLB Address Translation Flow

6.7.3 TLB Address Translation

A program references memory by using the effective address computed by the hardware when it executes a *Load, Store, Cache Management, or Branch* instruction, and when it fetches the next instruction. A virtual address is formed from the effective address as described in Section 6.7.2 and the virtual address is translated to a real address according to the procedures described in this section. The storage subsystem uses the real address for the access. All storage access effective addresses are translated to real addresses using the TLB mechanism. See Figure 20.

The virtual address is used to locate the associated entry in the TLB. The address space identifier, the process identifier, and the effective address of the storage access are compared to the Translation Address Space bit (TS), the Translation ID field (TID), and the value in the Effective Page Number field (EPN),

respectively, of each TLB entry. If the Embedded.Hypervisor category is supported, the Logical Partition ID and the Guest State bit are also compared to the Translation Logical Partition ID (TLPID) and Translation Guest State (TGS) of each TLB entry. Figure 21 illustrates the criteria for a virtual address to match a specific TLB entry for a direct TLB entry (IND = 0). See Section 6.7.4 for details on Page Table translation using an indirect TLB entry.

The virtual address of a storage access matches a direct TLB entry if the first four following conditions are true, and, additionally, if the Embedded.Page Table category is supported, the fifth condition is true, and, additionally, if the Embedded.Hypervisor category is supported, the last two conditions are true.

- The Valid bit of the TLB entry is 1.
- The value of the address specifier for the storage access (MSR_{IS} for instruction fetches, MSR_{DS} for

data storage accesses) is equal to the value in the TS bit of the TLB entry.

- The value of the process identifier in the PID register is equal to the value in the TID field of the TLB entry or the value of the TID field of the TLB entry is equal to 0.
- The contents of bits 0:n-1 of the effective address of the storage access are equal to the value of bits 0:n-1 of the EPN field of the TLB entry (where $n=64-\log_2(\text{page size in bytes})$ and *page size* is specified by the value of the SIZE field of the TLB entry). See Table 2 and Table 3.
- One of the following conditions is true.
 - The TLB array supports the IND bit ($\text{TLBnCFG}_{\text{IND}} = 1$) and the IND bit of the TLB entry is equal to 0.
 - The TLB array does not support the IND bit ($\text{TLBnCFG}_{\text{IND}} = 0$).
- Either the value of the logical partition identifier in LPIDR is equal to the value of the TLPID field of the TLB entry, or the value of the TLPID field of the TLB entry is equal to 0.
- The value of the guest state bit (MSR_{GS}) is equal to the value of the TGS bit of the TLB entry.

Table 2: Page Size and Effective Address to TLB EPN Comparison for MAV = 1.0

0b11111	2TB	$\text{EPN}_{0:22} = ? \text{EA}_{0:22}$

Programming Note

An implementation need not support all page sizes.

If the virtual address of the storage access matches a TLB entry in accordance with the selection criteria specified in the preceding paragraph, the value of the Real Page Number field (RPN) of the matching TLB entry provides the real page number portion of the real address. Let $n=64-\log_2(\text{page size in bytes})$ where *page size* is specified by the SIZE field of the TLB entry. Bits n:63 of the effective address are appended to bits 0:n-1 of the 54-bit RPN field of the matching TLB entry to produce the 64-bit real address (i.e. $\text{RA} = \text{RPN}_{0:n-1} \parallel \text{EA}_{n:63}$) that is presented to main storage to perform the storage access. The page size is determined by the value of the SIZE field of the matching TLB entry. See Table 4 and Table 5. Depending on the page size, certain RPN bits of the matching TLB entry must be zero as shown in Table 4 and Table 5. Otherwise, it is implementation-dependent whether the

address translation is performed as if these RPN bits are 0 or as if the corresponding RA bits are undefined values, or either an Instruction Storage exception (for an instruction fetch) or Data Storage exception (for a data access) occurs. If the specified page size is not supported by the implementation's TLB array, it is implementation-dependent whether the address translation is performed as if the page size was a smaller size or either an Instruction Storage exception (for an instruction fetch) or Data Storage exception (for a data access) occurs.

Table 4: Real Address Generation for MAV = 1.0

SIZE	Page Size (4 ^{SIZE} KB)	RPN Bits Required to be Equal to 0	Real Address

A TLB Miss exception occurs if there is no valid matching direct entry in the TLB for the page specified by the virtual address (Instruction or Data TLB Error interrupt) and, if the Embedded Page Table category is supported, there is no matching indirect entry (see Section 6.7.4). A TLB Miss exception for an instruction fetch will result in an Instruction TLB Miss exception type Instruction TLB Error interrupt. A TLB Miss exception for a data storage access will result in a Data TLB Miss exception type Data TLB Error interrupt. Although the possibility exists to place multiple direct and/or multiple indirect entries into the TLB that match a specific virtual address, assuming a set-associative or fully-associative organization, doing so is a programming error. Either one of the matching entries is used or a Machine Check exception occurs if there are multiple matching direct entries or multiple matching indirect entries for an instruction or data access.

The rest of the matching TLB entry provides the access control bits (UX, SX, UW, SW, UR, SR, VF), and stor-

age control attributes (ACM [implementation-dependent], VLE <VLE>, U0, U1, U2, U3, W, I, M, G, E) for the storage access. The access control bits and storage control attribute bits specify whether or not the access is allowed and how the access is to be performed. See Sections 6.7.6 and 6.11.4.

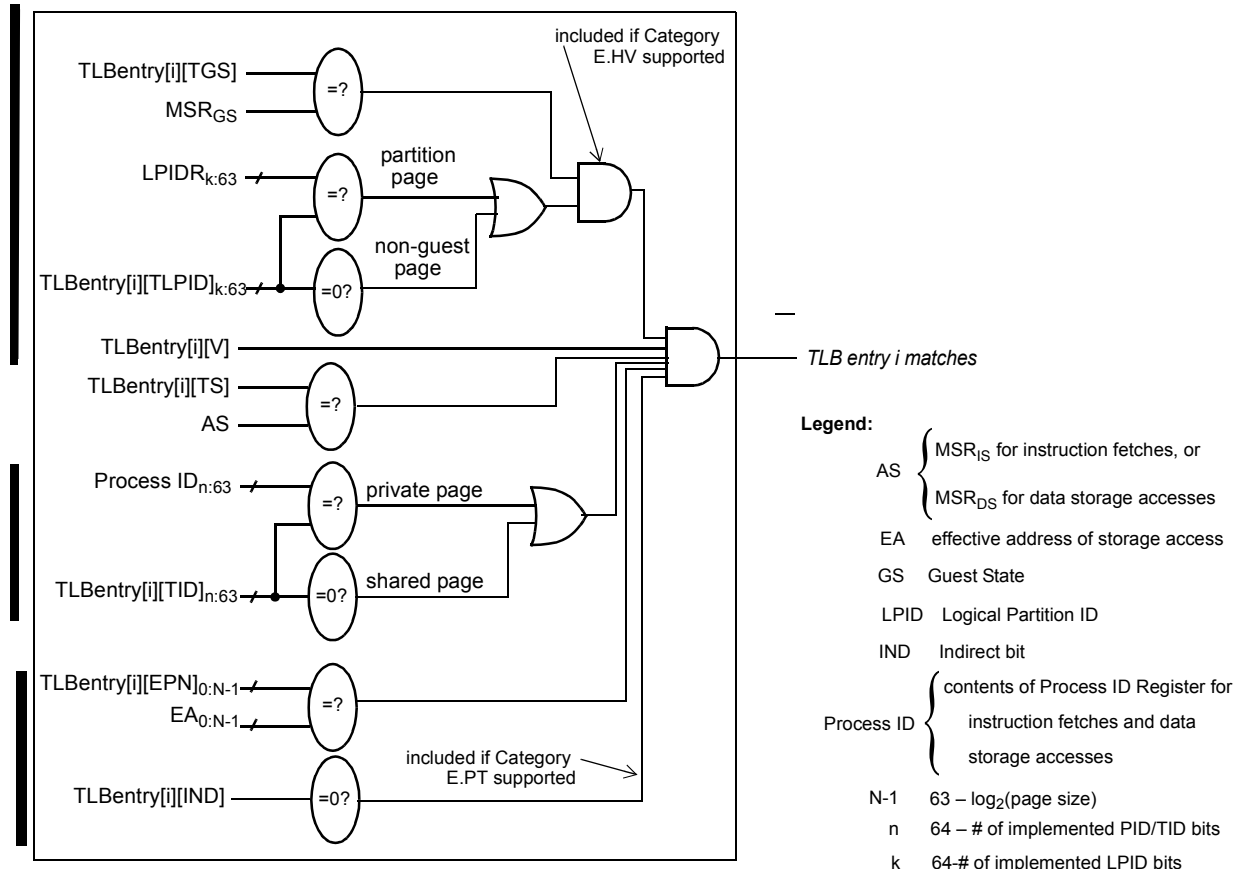

Figure 21. Address Translation: Virtual Address to direct TLB Entry Match Process

6.7.4 Page Table Address Translation [Category: Embedded.Page Table]

A hardware Page Table is a variable-sized data structure that specifies the mapping between virtual page numbers and real page numbers. There can be many hardware Page Tables. Each Page Table is defined by an indirect TLB entry. An indirect TLB entry is an entry that has its IND bit equal to 1.

An indirect TLB entry matches the virtual address if all fields match per Section 6.7.4 except for the IND bit and the IND bit of the TLB entry is 1. If there is no matching direct TLB entry, but there is one and only one matching indirect entry, the indirect entry is used to access a Page Table Entry (PTE) if the VF bit of the indirect TLB entry is 0. If the VF bit of this indirect TLB

entry is 1, a Virtualization Fault exception occurs. If the PTE is a valid entry (V bit = 1), the PTE is used to translate the address. The PTE includes the abbreviated RPN (ARPN), page size (PS), storage control (WIMGE), implementation-dependent bits, and storage access control bits (BAP,R,C) that are used for the access. If the Embedded.Page Table and Embedded.Hypervisor categories are both supported, the Embedded.Hypervisor.LRAT category is supported. In this case, the RPN from the PTE is treated as a Logical Page Number (LPN) and the LPN is translated by the LRAT into an RPN. See Section 6.9. If there is more than one matching direct TLB entry or more than one matching indirect TLB entry, any one of the duplicate entries may be used or Machine Check exception may occur.

See Section 6.7.5 for the rules that software must follow when updating the Page Table.

Programming Note

Even when the Embedded.Hypervisor category is supported, a Page Table can optionally be treated as a guest supervisor resource due to the LRAT.

If the Page Table is treated as a hypervisor resource, the Page Table must be placed in storage to which only the hypervisor has access. Moreover, the contents of the Page Table must be such that non-hypervisor software cannot modify storage that contains hypervisor programs or data. An LRAT identity mapping (LPN=RPN) can be used when the Page Tables are treated as hypervisor resources, especially if only one LRAT entry is provided. If the LRAT identity mapping converts LPNs into RPNs that extend beyond the memory given to the partition, the Page Table Entries still provide the hypervisor with a mechanism to limit a guest's accesses to memory assigned to the partition, assuming guest execution of *TLB Management* instructions is disabled.

Programming Note

If storage accesses are to scattered virtual pages, an Embedded Page Table could be sparsely used, and, in the worst case, there could be only one valid PTE in the Page Table. In this case it would be more efficient for software to directly load TLB entries rather than have both an indirect TLBE and a direct TLBE, which is loaded from the Page Table.

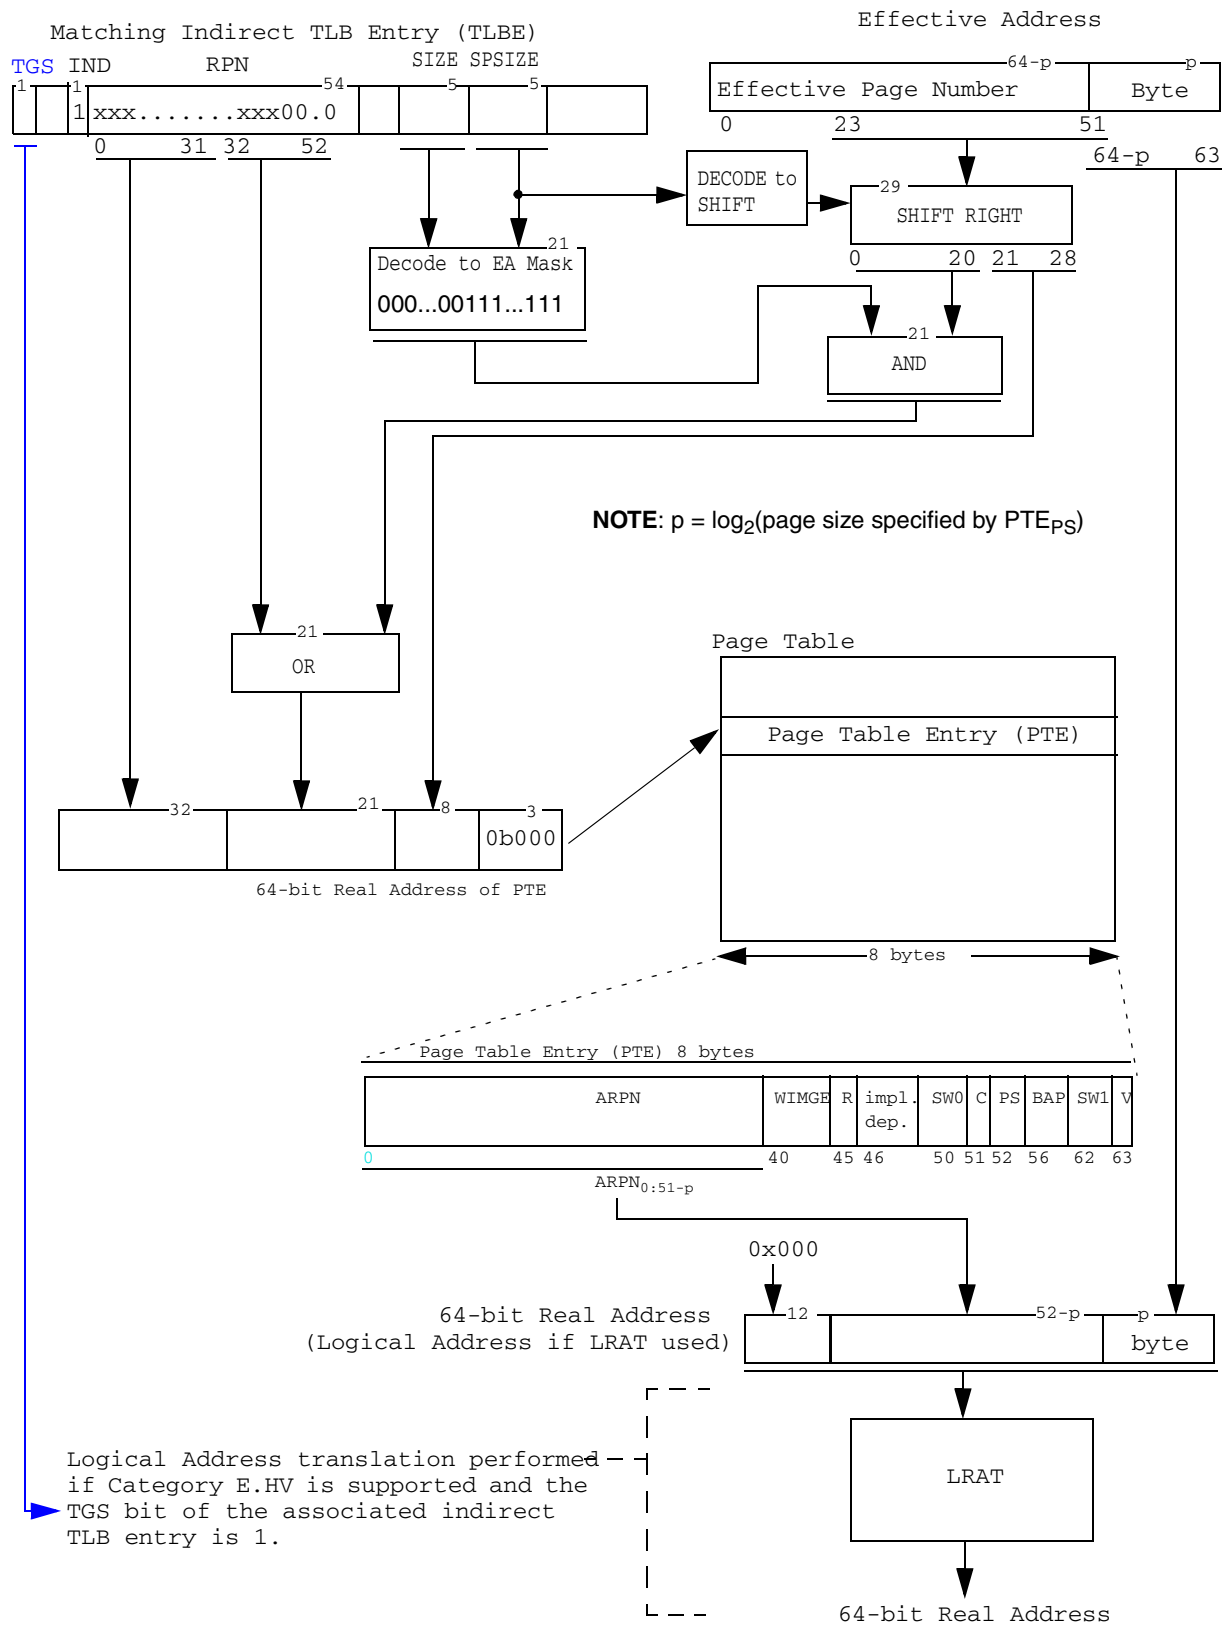

Figure 22. Page Table Translation

Figure 22 depicts the Page Table translation for a matching indirect TLB entry (TLBE). The Page Table Entry that is used to translate the Effective Address is selected by a real address formed from some combination of RPN bits from the TLBE and some EA bits. The low-order m bits of the RPN field in the indirect TLB entry must be zeros, where m is $(\text{SIZE} - \text{SPSIZE}) - 7$.

SIZE minus SPSIZE must be greater than 7 (corresponding to a page table size of at least 2 KB; see below under “Page Table Size and Alignment”). The SIZE and SPSIZE fields of the TLBE determine which bits of the RPN and EA are used in the following manner.

1. $\text{EA}_{23:51}$ are shifted right q bits, according to a decode of SPSIZE , to produce a 29-bit result S . The value of q is $(\text{SPSIZE} - 2)$. Bits shifted out of the rightmost bit position are lost.
2. A 21-bit EA mask is formed based on a decode of SIZE and SPSIZE . The EA mask is $(2^9 - (\text{SIZE} - \text{SPSIZE}))_0 \parallel (\text{SIZE} - \text{SPSIZE})_{8:1}$.
3. The EA mask from step 2 is ANDed with the high-order 21 bits of the shifted EA result ($S_{0:20}$) from step 1 to form a 21-bit result.
4. $\text{RPN}_{32:52}$ from the indirect TLB entry is ORed with the 21-bit result from step 3 to form a 21-bit result R .
5. The real address of the PTE is formed as follows:

$$\text{RA} = \text{TLBE}_{\text{RPN}[0:31]} \parallel R \parallel S_{21:28} \parallel 0b000$$

The doubleword addressed by the real address result from step 5 is the PTE used to translate the EA if the PTE is valid (Valid bit = 1). If the PTE is valid, PTE_{PS} must be greater than or equal to the SPSIZE of the associated indirect TLB entry and must be less than or equal to the SIZE of the associated indirect TLB entry. The real address (RA) result is formed by concatenating $0x000$ with the $\text{ARP}_{\text{N}}_{0:51-p}$ from the PTE and with the low-order p bits of EA, where p is equal to $\log_2(\text{page size specified by } \text{PTE}_{\text{PS}})$.

$$\text{RA} = 0x000 \parallel \text{ARP}_{\text{N}}_{0:51-p} \parallel \text{EA}_{64-p:63}$$

However, if an implementation supports a real address with only r bits, $r < 52$, and either the Embedded.Hypervisor category is not supported or the TGS bit of the corresponding indirect TLB entry is 0, the high-order $52-r$ bits of $\text{PTE}_{\text{ARP}_{\text{N}}}$ are ignored and treated as 0s. If the Embedded.Hypervisor category is supported, an implementation supports a logical address with only q bits, $q < 52$, and the TGS bit of the corresponding indirect TLB entry is 1, the high-order $52-q$ bits of $\text{PTE}_{\text{ARP}_{\text{N}}}$ are ignored and treated as 0s.

If the Embedded.Hypervisor category is supported and the TGS bit of the associated indirect TLB entry is 1, the RA formed from the PTE is treated as a logical real address and translated by the LRAT. If there is no matching entry in the LRAT, an LRAT Miss exception

occurs. See Section 6.9. If an LRAT Error interrupt results from this exception, ESR_{PT} is set to 1.

If the Page Table Entry that is accessed is invalid (Valid bit = 0), a Page Table Fault exception occurs. An Execute, Read, or Write Access Control exception occurs if a valid PTE is found but the access is not allowed by the access control mechanism. These exceptions are types of Instruction Storage exception or Data Storage exception, depending on whether the effective address is for an instruction fetch or for a data access. See Section 7.6.4 and Section 7.6.5 for additional information about these and other interrupt types. For either of these interrupts caused by a Page Table Fault exception or Execute, Read, or Write Access Control exception due to PTE permissions, ESR_{PT} or GESR_{PT} is set to 1 (GESR_{PT} if the Embedded.Hypervisor.LRAT category is supported and the interrupt is directed to the guest. Otherwise, ESR_{PT}).

Programming Note

If PTE_{PS} is greater than the SPSIZE of the associated indirect TLB entry, $2^{(\text{PS} - \text{SPSIZE})}$ PTEs are needed for the virtual page to ensure there is no Page Table Fault exception for accesses to the page regardless of the location of the access within the page. If a Page Table Fault exception for some accesses to the page is acceptable, there is no requirement that all such PTEs for the page be valid.

Programming Note

The computation of the real address of the PTE can be understood as follows. (Some of the facts mentioned below, such as the fact that the minimum Page Table size is 2K, are covered later in the section.)

1. q is the number of EA bits above bit 52 that are part of the byte offset within the effective page. (The minimum size of a page that is mapped by a PTE is 4K, so $EA_{52:63}$ are always part of the byte offset, and $SPSIZE$ must be at least 2.) S is the low-order 29- q bits of the EPN, prepended with q 0s.
2. The EA-mask has a number of low-order 1 bits equal to the difference between $\log_2(\# \text{ PTEs})$ and $\log_2(\text{minimum } \# \text{ PTEs}) = 8$. (The \log_2 of the number of PTEs in a Page Table is $SIZE - SPSIZE$. The minimum Page Table size is 2K and PTE size = 8 bytes, so the minimum number of PTEs is $2^{11} \div 2^3 = 2^8$.) Call this number s ; i.e., $s = (SIZE - SPSIZE) - 8$, and the \log_2 of the number of PTEs in the Page Table is $s+8$.
3. The result is the low-order s bits of the EPN that are immediately above the lowest-order 8 EPN bits (the lowest-order 8 bits are always used to select the PTE), prepended with 21- s 0s. (If s could be greater than $(29-q)-8$, the "EPN" bits included in the result could include 0 bits that were shifted in step 1. However, this would correspond to $(SIZE - SPSIZE) - 8 > (31 - SPSIZE) - 8$, which would imply $SIZE > 31$, which is impossible.)
4. R consists of the high-order 21- s bits of $RPN_{32:52}$ followed by the low-order s bits of the EPN that are immediately above the lowest-order 8 EPN bits.
5. The real address of the PTE thus consists of the high-order 53- s bits of the RPN from the TLB entry, followed by the low-order $s+8$ bits of the EPN (recall that $s+8$ is the number of PTEs in the Page Table), followed by 3 0s.

Storage Control Attributes for the Page Table

A Page Table must be located in storage that is Big-Endian, Memory Coherence Required, not Caching Inhibited and not Guarded. If the translation of a virtual address matches an indirect TLB entry that has its storage control attribute E bit equal to 1, M bit equal to 0, I bit equal to 1, or G bit = 1, it is implementation-dependent whether the translation is performed as if valid values were substituted for the invalid values or as if the entry doesn't match, or either an Instruction Storage exception (for an instruction fetch) or Data Storage exception (for a data access) occurs. The Page Table is allowed to be located in storage that is Write Through Required or Not Write Through Required. However, the

same W value must be used for a single thread's indirect and direct TLB entries that map the same PTE. The Implementations may require specific values for ACM and U0:U3.

Ordering of Implicit Accesses to the Page Table

The definition of "performed" given in Books II and III-E applies also to the implicit accesses to the Page Table by the thread in performing address translation. Accesses for performing address translation are considered to be loads in this respect. These implicit accesses are ordered by the **sync** instruction with $L=0$ as described below.

The *Synchronize* instruction is described in Section 4.4.3 of Book II, but only at the level required by an application programmer (**sync** with $L=0$ or $L=1$). This section describes properties of the instruction that are relevant only to operating system and hypervisor software programmers. The **sync** instruction with $L=0$ (**sync**) has the following additional properties.

- The **sync** instruction provides an ordering function for all stores to the Page Table caused by *Store* instructions preceding the **sync** instruction with respect to lookups of the Page Table that are performed, by the thread executing the **sync** instruction, after the **sync** instruction completes. Executing a **sync** instruction ensures that all such stores will be performed, with respect to the thread executing the **sync** instruction, before any implicit accesses to the affected Page Table Entries, by such Page Table lookups, are performed with respect to that thread.
- In conjunction with the *tlbivax* and *tlbsync* instructions, the **sync** instruction provides an ordering function for TLB invalidations and related storage accesses on other threads as described in the *tlbsync* instruction description on page 1010.

Programming Note

For instructions following a **sync** instruction, the memory barrier need not order implicit storage accesses for purposes of address translation.

Page Table Entry

Each Page Table Entry (PTE) maps a VPN to an RPN. If the corresponding indirect TLB entry has an LPID <E.HV> or PID value of zero, multiple VPNs are mapped by a single PTE in a Page Table pointed to by

such an indirect TLB entry. Figure 23 shows the layout of a PTE.

Bit(s)	Name	Description
0:39	ARPN	Abbreviated Real Page Number
40:44	WIMGE	Storage control attributes
45	R	Reference bit
46:49	impl.-dep.	Implementation-dependent. These bits can be used to support User-Definable Storage Control Attributes, ACM and VLE. These bits are used in any combination of the following or subsets of the following: <ul style="list-style-type: none"> ■ 46:49 - User-Definable Storage Control Attributes (U0:U3) ■ 48 - ACM ■ 49 - VLE <VLE>
50	SW0	Available for software use
51	C	Change bit
52:55	PS	Page Size (real)
56:61	BAP	Base Access Permission bits: <ul style="list-style-type: none"> 0: Base UX 1: Base SX 2: Base UW 3: Base SW 4: Base UR 5: Base SR
62	SW1	Available for software use
63	V	Entry valid (V=1) or invalid (V=0)

Figure 23. Page Table Entry

The Page Size (PS) field encodes page sizes using the same encodes as the TLB_{SIZE} , except that 0b0 is prepended to the 4-bit PS value (0 || PS) to form the equivalent 5-bit encode and PS must specify a page size of 4 KB or larger. See Table 3 on page 951.

The Abbreviated Real Page Number (ARPN) field contains the least significant 40 bits of the RPN. The full RPN associated with the PTE is formed from the ARPN prepended with 0x000, i.e. $RPN = 0x000 || ARPN$. Depending on the page size, certain ARPN bits must be zero. Specifically, if $p > 12$, $ARP_{52-p:39}$ must be zeros, where $p = \log_2(\text{page size specified by } PTE_{PS})$. If an implementation supports a real address with only $r < 52$, and either the Embedded.Hypervisor category is not supported or the TGS bit of the corresponding indirect TLB entry is 0, the high-order $52-r$ bits of $PTE_{ARP_{N}}$ are ignored and treated as 0s for address translation. If the Embedded.Hypervisor category is supported, an implementation supports a logical

address with only q bits, $q < 52$, and the TGS bit of the corresponding indirect TLB entry is 1, the high-order $52-q$ bits of $PTE_{ARP_{N}}$ are ignored and treated as 0s for address translation.

The Base Access Permission (BAP) bits are used together with the Reference (R) and Change (C) bits to derive the storage access control bits that are used for the access. Table 6 shows how the storage access control bits are derived from the BAP, R, and C bits of the Page Table Entry.

Table 6: Storage Access Control Bits Derived from a Page Table Entry

Derived Storage Access Control	Page Table Values
UX	$BAP_0 \& R$
SX	$BAP_1 \& R$
UW	$BAP_2 \& R \& C$
SW	$BAP_3 \& R \& C$
UR	$BAP_4 \& R$
SR	$BAP_5 \& R$

Programming Note

Unlike many architectures, the R and C bits in a Page Table entry are not updated by hardware.

Programming Note

The page size specified by PTE_{PS} must be consistent with the page sizes supported by a direct TLB entry of a TLB array that can be loaded from the Page Table.

An implementation need not support all page sizes.

Page Table Size and Alignment

A Page Table's size is $8 \times 2^{(SIZE - SPSIZE)}$, where $SIZE$ is the page size specified by the $SIZE$ field of the indirect TLB entry used to access the Page Table and $SPSIZE$ is the sub-page size specified by the $SPSIZE$ field of this indirect TLB entry. Page Table sizes smaller than 2 KB are not allowed and $SPSIZE$ must be greater than or equal to 2. This implies that the Page Table size s is $2 \text{ KB} \leq s \leq 4 \text{ GB}$. The Page Table is aligned on a boundary that is a multiple of its size.

TLB Update

As a result of a Page Table translation, a corresponding direct TLB entry is created if no exception occurs, is optionally created if certain exceptions occur, and is not created if certain other exceptions occur.

If no exception occurs, a direct TLB entry is written to create an entry corresponding to the virtual address and the contents of the PTE that was used to translate the virtual address. In this case, hardware selects the TLB array and TLB entry to be written. Any TLB array

that meets all the following criteria can be selected by the hardware.

- The TLB array supports the page size specified by PTE_{PS} .
- The TLB array can be loaded from the Page Table ($TLBnCFG_{PT} = 1$).

If no TLB array can be selected based on these criteria, then a TLB Ineligible exception occurs. Hardware also selects the entry within the TLB array based on some implementation-dependent algorithm. However, a valid TLB entry with $IPROT = 1$ must not be overwritten. If all TLB entries that can be used for a specific virtual page have $IPROT = 1$, then a TLB Ineligible exception occurs. In the absence of a higher priority exception, an Instruction Storage or Data Storage interrupt occurs, depending on whether the Page Table translation was due to an instruction fetch or data access and ESR_{TLBI} is set to 1. An Instruction Storage or Data Storage interrupt resulting from a TLB Ineligible exception is always directed to hypervisor state.

It is implementation-dependent whether a TLB entry is written as a result of a Page Table translation if a Page Table Fault exception occurs, but, if written, the valid bit of the TLB entry is set to 0. It is implementation-dependent whether a TLB entry is written as a result of a Page Table translation if an Execute, Read, or Write Access Control exception occurs.

A TLB entry is not written as a result of a Page Table translation if an LRAT Miss exception occurs or a TLB Ineligible exception occurs.

If a TLB entry is written, the entry is written based on the values shown in Table 7.

Table 7: TLB Update after Page Table Translation

TLB field	Load Value
EPN _{0:p-1}	EA _{0:p-1} , where $p = 64 - \log_2(\text{page size in bytes})$ and page size is specified by PTE _{PS} . Any low-order EPN bits in the TLB entry that correspond to byte offsets with the page are undefined.
TS	TS from indirect TLB entry
SIZE	PTE _{PS}
TLPID [Category: E.HV]	TLPID from indirect TLB entry
TGS [Category: E.HV]	TGS from indirect TLB entry
TID	TID from indirect TLB entry
V	PTE _V
IND	0
RPN	if E.HV.LRAT not supported, then RPN = 0x000 PTE _{ARPN} 0b00 else LPN = 0x000 PTE _{ARPN} 0b00 RPN = result of LRAT translation of LPN & PTE _{PS}
WIMGE	PTE _{WIMGE}
U0:U3, ACM, VLE	PTE _{impl.-dep.} (which of the imple- mentation-dependent TLB bits are loaded and which of the PTE _{46:49} bits is used to load each TLB bit are implementation- dependent)
UR, UW, UX, SR, SW, SX	Derived Storage Access Control from PTE _{BAP} , PTE _R , and PTE _C . See Table 6.
VF	0
IPROT	0

If implementations write TLB entries for out-of-order Page Table translations, a mechanism for disabling such TLB updates must be provided by the implementation in order for software to preload a TLB array without the possibility of creating multiple direct entries for the same virtual address.

Programming Note

As a hardware simplification the architecture allows a TLB entry to be written with the valid bit set to 0 if a Page Table Fault exception occurs. A replacement of a valid TLB entry by an invalid entry is typically not a significant performance impact since software often swaps in the virtual page and creates a valid PTE for the page.

Programming Note

Only software creates indirect TLB entries, but both software and hardware create direct TLB entries. Unless a *TLB Write Conditional* instruction is used, software must avoid creating a direct TLB entry for a VPN that may also be simultaneously translated via a Page Table by a thread sharing the TLB. Otherwise multiple, direct TLB entries could be created. If software is preloading a TLB with a direct TLB entry and there is already an indirect TLB entry that could be used to translate the same VPN, software must ensure that no program on any thread sharing the TLB is accessing the VPN. Otherwise multiple, direct TLB entries could be created. If the Embedded.TLB Write Conditional category is supported, a *TLB Write Conditional* instruction can be used to create a direct TLB entry for the same VPN that may also be mapped by an existing indirect entry and Page Table Entry, assuming the page size specified by the *TLB Write Conditional* and PTE are identical.

6.7.5 Page Table Update Synchronization Requirements [Category: Embedded.Page Table]

This section describes rules that software must follow when updating the Page Table. Otherwise, TLB entries for outdated PTEs may remain valid. This section includes suggested sequences of operations for some representative cases.

In the sequences of operations shown in the following subsections, any alteration of a Page Table Entry (PTE) that corresponds to a single line in the sequence is assumed to be done using a *Store* instruction for which the access is atomic. Appropriate modifications must be made to these sequences if this assumption is not satisfied (e.g., if a store doubleword operation is done using two *Store Word* instructions).

As described in Section 6.5, stores are not performed out-of-order. Moreover, address translations associated with instructions preceding the corresponding Store instructions are not performed again after the stores have been performed. (These address translations must have been performed before the store was determined to be required by the sequential execution model, because they might have caused an exception.) As a result, an update to a PTE need not be preceded by a context synchronizing operation.

All of the sequences require a context synchronizing operation after the sequence if the new contents of the PTE are to be used for address translations associated with subsequent instructions.

As noted in the description of the *Synchronize* instruction in Section 4.4.3 of Book II, address translation

associated with instructions which occur in program order subsequent to the *Synchronize* may actually be performed prior to the completion of the *Synchronize*. To ensure that these instructions and data which may have been speculatively fetched are discarded, a context synchronizing operation is required.

Programming Note

In many cases this context synchronization will occur naturally; for example, if the sequence is executed within an interrupt handler the *rfid* or *hrfid* instruction that returns from the interrupt handler may provide the required context synchronization.

Page Table Entries must not be changed in a manner that causes an implicit branch.

6.7.5.1 Page Table Updates

TLBs are non-coherent caches of the Page Table. TLB entries must be invalidated explicitly with one of the methods described in Section 6.11.4.3.

Unsynchronized lookups in the Page Table continue even while it is being modified. Any thread, including a thread on which software is modifying the Page Table, may look in the Page Table at any time in an attempt to translate a virtual address. When modifying a PTE, software must ensure that the PTE's Valid bit is 0 if the PTE is inconsistent (e.g., if the BAP field is not correct for the current ARPN field).

The sequences of operations shown in the following subsections assume a multi-threaded processor environment. In a system consisting of only a single-threaded processor the *tlbsync* must be omitted, and the *mbar* that separates the *tlbivax* from the *tlbsync* can be omitted. In a multi-threaded processor environment, when *tlbilx* [Category: E.HV] is used instead of *tlbivax* in a Page Table update, the synchronization requirements are the same as when *tlbivax* is used in a system consisting of only a single-threaded processor.

Programming Note

For all of the sequences shown in the following subsections, if it is necessary to communicate completion of the sequence to software running on another thread, the *sync* instruction at the end of the sequence should be followed by a *Store* instruction that stores a chosen value to some chosen storage location X. The memory barrier created by the *sync* instruction ensures that if a *Load* instruction executed by another thread returns the chosen value from location X, the sequence's stores to the Page Table have been performed with respect to that other thread. The *Load* instruction that returns the chosen value should be followed by a context synchronizing instruction in order to ensure that all instructions following the context synchronizing instruction will be fetched and executed using the values stored by the sequence (or values stored subsequently). (These instructions may have been fetched or executed out-of-order using the old contents of the PTE.)

This Note assumes that the Page Table and location X are in storage that is Memory Coherence Required.

6.7.5.1.1 Adding a Page Table Entry

This is the simplest Page Table case. The Valid bit of the old entry is assumed to be 0. The following sequence can be used to create a PTE, maintain a consistent state, and ensure that a subsequent reference to the virtual address translated by the new entry will use the correct real address and associated attributes.

```
PTEARPN, WIMGE, R, SW0, C, PS, BAP, SW1, V ← new values
sync /* order updates before next
      Page Table lookup and before
      next data access. */
```

On a 32-bit implementation, the following sequence can be used.

```
PTEARPN(0:31) ← new value
mbar /* order 1st update before 2nd */
PTEARPN[32:39], WIMGE, R, SW0, C, PS, BAP, SW1, V ← new values
sync /* order updates before next
      Page Table lookup and before
      next data access. */
```

6.7.5.1.2 Deleting a Page Table Entry

The following sequence can be used to ensure that the translation instantiated by an existing entry is no longer available.

```
PTEV ← 0 /* (other fields don't matter) */
sync /* order update before tlbivax and
      before next Page Table lookup */
tlbivax(old_LPID, old_GS, old_PID, old_AS, old_VA,
        old_ISIZE, old_IND)
/*invalidate old translation*/
mbar /* order tlbivax before tlbsync */
tlbsync /* order tlbivax before sync */
sync /* order tlbivax, tlbsync, and update
      before next data access */
```

6.7.5.1.3 Modifying a Page Table Entry

General Case

If a valid entry is to be modified and the translation instantiated by the entry being modified is to be invalidated, the old PTE can be deleted and a new one added using the sequences described in the two preceding sections, in order to ensure that the translation instantiated by the old entry is no longer available, maintain a consistent state, modify the PTE, and ensure that a subsequent reference to the virtual address translated by the new entry will use the correct real address and associated attributes.

Modifying the SW0 and SW1 Fields

If the only change being made to a valid entry is to modify the SW0 or SW1 fields, the following sequence suffices because the SW0 and SW1 fields are not used by the thread.

```
loop: ldarx r1 ← PTE /* load of PTE */
      r1 ← new SW0, SW1 /* replace SW0, SW1 in r1 */
      stdcx. PTE ← r1 /* store of PTE
        if still reserved (new SW0 or SW1
        values, other fields unchanged) */
      bne- loop /* loop if lost reservation */
```

A *lwarx/stwcx*. pair (specifying the low-order word of the PTE) can be used instead of the *ldarx/stdcx*. pair shown above.

Modifying a Reference or Change Bit

If the only change being made to a valid entry is to modify the R bit, the C bit or both, the preceding

sequence suffices if the precise instant that hardware Page Table translations use the new value doesn't matter. Reference, Change, and Valid bits are in different bytes to facilitate the use of a *Store* instruction of a byte to modify a Reference or Change bit instead of a *ldarx* and *stdcx*. However, the correctness of doing so is a software issue beyond the scope of this architecture.

Modifying the Virtual Address

If the virtual address translated by a valid PTE is to be modified and the new virtual address maps to the same PTE as does the old virtual address, the following sequence can be used to modify the PTE, maintain a consistent state, ensure that the translation instantiated by the old entry is no longer available, and ensure that a subsequent reference to the virtual address translated by the new entry will use the correct real address and associated attributes. This instruction sequence depends on an atomic doubleword store of the PTE. In 32-bit mode, the instruction sequence shown for the general case must be used.

```
PTEU0:U3, ARPN, PS, BAP, R, C, WIMGE, SW0:1, V ← new values
/* Set PTE to new values with V=1 */
sync /* order update before tlbivax and
      before next Page Table lookup */
tlbivax(old_LPID, old_GS, old_PID, old_AS, old_VA,
        old_ISIZE, old_IND)
/*invalidate old translation*/
mbar /* order tlbivax before tlbsync */
tlbsync /* order tlbivax before sync */
sync /* order tlbivax, tlbsync, and update
      before next data access */
```

6.7.5.2 Invalidating an Indirect TLB Entry

The following sequence can be used to ensure that translations by a Page Table that is mapped via an indirect entry will no longer occur and that the storage used for the Page Table can then be re-used for other purposes.

```
for all valid PTEs mapped by the indirect TLB entry
PTEV ← 0 /* (other fields don't matter) */
sync /* order stores to PTEs */
for all valid PTEs mapped by the indirect TLB entry
  tlbivax(old_LPID, old_GS, old_PID, old_AS, old_VA,
        old_ISIZE, MAS6SIND = 0)
/*invalidate old PTE translations*/
tlbivax(old_LPID, old_GS, old_PID, old_AS, old_VA,
        old_ISIZE, MAS6SIND = 1)
/*invalidate old indirect TLB entry */
mbar /* order tlbivax before tlbsync */
tlbsync /* order tlbivax before sync */
sync /* order tlbivax, tlbsync, and update
      before next data access to the storage
      locations occupied by the Page Table
      pointed to by the old indirect TLBE */
```

6.7.6 Storage Access Control

After a matching TLB entry has been identified, the access control mechanism selectively grants execute access, read access, and write access separately for user mode versus supervisor mode. If the Embedded.Hypervisor category is supported, the access control mechanism selectively controls an access so that the access can be virtualized by the hypervisor if appropriate. Figure 24 illustrates the access control process and is described in detail in Sections 6.7.6.1 through 6.7.6.6.

An Execute, Read, or Write Access Control exception or Virtualization Fault exception occurs if the appropriate TLB entry is found but the access is not allowed by the access control mechanism (Instruction or Data Storage interrupt). See Section 7.6 for additional information about these and other interrupt types. In certain cases, Execute, Read, and Write Access Control exceptions and Virtualization Fault exceptions may result in the restart of (re-execution of at least part of) a *Load* or *Store* instruction.

Implementations may provide additional access control capabilities beyond those described here.

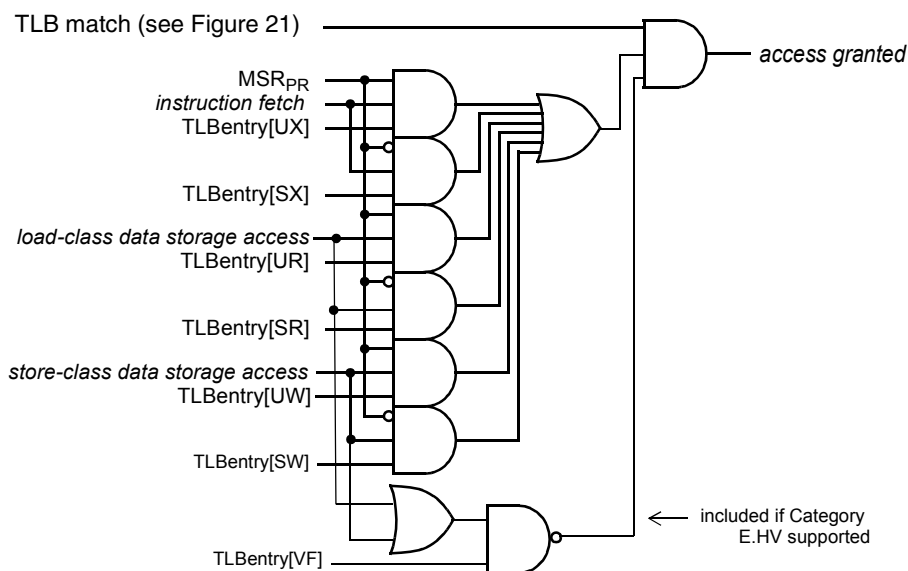

Figure 24. Access Control Process

6.7.6.1 Execute Access

The UX and SX bits of the TLB entry control *execute* access to the page (see Table 8).

Instructions may be fetched and executed from a page in storage while in user state ($MSR_{PR}=1$) if the UX access control bit for that page is equal to 1. If the UX access control bit is equal to 0, then instructions from that page will not be fetched, and will not be placed into any cache as the result of a fetch request to that page while in user state.

Instructions may be fetched and executed from a page in storage while in supervisor state ($MSR_{PR}=0$) if the SX access control bit for that page is equal to 1. If the SX access control bit is equal to 0, then instructions from that page will not be fetched, and will not be placed into any cache as the result of a fetch request to that page while in supervisor state.

Instructions from no-execute storage may be in the instruction cache if they were fetched into that cache

when their effective addresses were mapped to execute permitted storage. Software need not flush a page from the instruction cache before marking it no-execute.

Furthermore, if the sequential execution model calls for the execution of an instruction from a page that is not enabled for execution (i.e. $UX=0$ when $MSR_{PR}=1$ or $SX=0$ when $MSR_{PR}=0$), an Execute Access Control exception type Instruction Storage interrupt is taken.

6.7.6.2 Write Access

The UW and SW bits of the TLB entry control *write* access to the page (see Table 8).

Store operations (including *Store-class Cache Management* instructions) are permitted to a page in storage while in user state ($MSR_{PR}=1$) if the UW access control bit for that page is equal to 1. If the UW access control bit is equal to 0, then execution of the *Store* instruction is suppressed and a Write Access Control exception type Data Storage interrupt is taken.

Store operations (including *Store-class Cache Management* instructions) are permitted to a page in storage while in supervisor state ($MSR_{PR}=0$) if the SW access control bit for that page is equal to 1. If the SW access control bit is equal to 0, then execution of the *Store* instruction is suppressed and a Write Access Control exception type Data Storage interrupt is taken.

6.7.6.3 Read Access

The UR and SR bits of the TLB entry control *read* access to the page (see Table 8).

Load operations (including *Load-class Cache Management* instructions) are permitted from a page in storage while in user state ($MSR_{PR}=1$) if the UR access control bit for that page is equal to 1. If the UR access control bit is equal to 0, then execution of the *Load* instruction is suppressed and a Read Access Control exception type Data Storage interrupt is taken.

Load operations (including *Load-class Cache Management* instructions) are permitted from a page in storage while in supervisor state ($MSR_{PR}=0$) if the SR access control bit for that page is equal to 1. If the SR access control bit is equal to 0, then execution of the *Load* instruction is suppressed and a Read Access Control exception type Data Storage interrupt is taken.

6.7.6.4 Virtualized Access <E.HV>

The VF bit of the TLB entry prevents a Load or Store access to the page (see Table 8).

The translation of a *Load* or *Store* (including *Cache Management* instructions) operand address that uses a TLB entry with the Translation Virtualization Fault field equal to 1 causes a Virtualization Fault exception type Data Storage interrupt regardless of the settings of the permission bits and regardless of whether the TLB entry is a direct or indirect entry. The resulting Data Storage interrupt is directed to the hypervisor state.

6.7.6.5 Storage Access Control Applied to Cache Management Instructions

dcbi, *dcbz*, and *dcbzep* instructions are treated as *Stores* since they can change data (or cause loss of data by invalidating a dirty line). As such, they can cause Write Access Control exception type Data Storage interrupts. If an implementation first flushes a line before invalidating it during a *dcbi*, the *dcbi* is treated as a *Load* since the data is not modified.

dcbi instructions are treated as *Stores* since they can change data. However, they do not cause Write Access Control exceptions. A *dcbi* instruction will not cause a virtualization fault ($TLB_{VF} = 1$).

dcbic, *dcbtls*, *icbi* and *icbiep* instructions are treated as *Loads* with respect to protection. As such, they can cause Read Access Control exception type Data Stor-

age interrupts and Virtualization Fault exception type Data Storage interrupts.

dcbt, *dcbtep*, *dcbtst*, *dcbtstep*, and *icbt* instructions are treated as *Loads* with respect to protection. However, they do not cause Read Access Control exceptions. A virtualization fault on these instructions will not result in a Data Storage interrupt.

It is implementation-dependent whether *dcbtstls* instructions are treated as *Loads* or *Stores* with respect to protection. As such, they can cause either Read Access Control exception type Data Storage interrupts or Write Access Control exception type Data Storage interrupts and can also cause Virtualization Fault exception type Data Storage interrupts.

dcbf, *dcbfep*, *dcbst*, and *dcbstep* instructions are treated as *Loads* with respect to protection. Flushing or storing a line from the cache is not considered a *Store* since the store has already been done to update the cache and the *dcbf*, *dcbfep*, *dcbst*, or *dcbstep* instruction is only updating the copy in main storage. As a *Load*, they can cause Read Access Control exception type Data Storage interrupts and Virtualization Fault exception type Data Storage interrupts.

Table 8: Storage Access Control Applied to Cache Instructions

Instruction	Read Protection Violation	Write Protection Violation	Virtualization Fault ¹
dcbi	No	No	No
dcbf	Yes	No	Yes
dcbfep	Yes	No	Yes
dcbi	Yes ³	Yes ³	Yes
dcbic	Yes	No	Yes
dcbst	Yes	No	Yes
dcbstep	Yes	No	Yes
dcbt	No	No	No
dcbtep	No	No	No
dcbtstls	Yes	No	Yes
dcbtst	No	No	No
dcbtstep	No	No	No
dcbtstls	Yes ⁴	Yes ⁴	Yes ⁴
dcbz	No	Yes	Yes
dcbzep	No	Yes	Yes
dci	No	Yes	Yes
icbi	Yes	No	Yes
icbiep	Yes	No	Yes
icbic	Yes ²	No	Yes
icbt	No	No	No
icbtstls	Yes ²	No	Yes
ici	No	No	No

Table 8: Storage Access Control Applied to Cache Instructions

Instruction	Read Protection Violation	Write Protection Violation	Virtualization Fault ¹
1. Category: Embedded.Hypervisor 2. <i>icbtl</i> s and <i>icblc</i> require execute or read access. 3. <i>dcbl</i> may cause a Read or Write Access Control Exception based on whether the data is flushed prior to invalidation. 4. It is implementation-dependent whether <i>dcbtstls</i> is treated as a <i>Load</i> or a <i>Store</i> .			

6.7.6.6 Storage Access Control Applied to String Instructions

When the string length is zero, neither *lswx* nor *stswx* can cause Data Storage interrupts.

6.8 Storage Control Attributes

This section describes aspects of the storage control attributes that are relevant only to privileged software programmers. The rest of the description of storage control attributes may be found in Section 1.6 of Book II and subsections.

6.8.1 Guarded Storage

Storage is said to be “well-behaved” if the corresponding real storage exists and is not defective, and if the effects of a single access to it are indistinguishable from the effects of multiple identical accesses to it. Data and instructions can be fetched out-of-order from well-behaved storage without causing undesired side effects.

Storage is said to be Guarded if the G bit is 1 in the TLB entry that translates the effective address.

In general, storage that is not well-behaved should be Guarded. Because such storage may represent a control register on an I/O device or may include locations that do not exist, an out-of-order access to such storage may cause an I/O device to perform unintended operations or may result in a Machine Check.

Instruction fetching is not affected by the G bit.

The following rules apply to in-order execution of *Load* and *Store* instructions for which the first byte of the storage operand is in storage that is both Caching Inhibited and Guarded.

- *Load* or *Store* instruction that causes an atomic access

If any portion of the storage operand has been accessed and an asynchronous or imprecise inter-

rupt is pending, the instruction completes before the interrupt occurs.

- *Load* or *Store* instruction that causes an Alignment exception, a Data TLB Error exception, or that causes a Data Storage exception.

The portion of the storage operand that is in Caching Inhibited and Guarded storage is not accessed.

Programming Note

Instruction fetching from Guarded storage is permitted. If instruction fetches from Guarded storage must be prevented, software must set access control bits for such pages to no-execute (i.e. UX=0 and SX=0).

6.8.1.1 Out-of-Order Accesses to Guarded Storage

In general, Guarded storage is not accessed out-of-order. The only exception to this rule is the following.

Load Instruction

If a copy of any byte of the storage operand is in a cache then that byte may be accessed in the cache or in main storage.

6.8.2 User-Definable

User-definable storage control attributes control user-definable and implementation-dependent behavior of the storage system. The existence of these bits is implementation-dependent. These bits are both implementation-dependent and system-dependent in their effect. These bits may be used in any combination and also in combination with the other storage control attribute bits.

6.8.3 Storage Control Bits

Storage control attributes are specified on a per-page basis. These attributes are specified in storage control bits in the TLB entries. The interpretation of their values is given in Figure 25.

Bit	Storage Control Attribute
W ^{1,6}	0 - not Write Through Required 1 - Write Through Required
I ⁶	0 - not Caching Inhibited 1 - Caching Inhibited
M ²	0 - not Memory Coherence Required 1 - Memory Coherence Required
G	0 - not Guarded 1 - Guarded
E ³	0 - Big-Endian 1 - Little-Endian
U0-U3 ⁴	User-Definable
VLE ⁵	0 - non Variable Length Encoding (VLE). 1 - VLE
ACM ⁷	0 - not Alternate Coherency Mode 1 - Alternate Coherency Mode (if M=1)
<p>¹ Support for the 1 value of the W bit is optional. Implementations that do not support the 1 value treat the bit as reserved and assume its value to be 0.</p> <p>² Support of the 1 value is optional for implementations that do not support multiprocessing, implementations that do not support this storage control attribute assume the value of the bit to be 0, and setting M=1 in a TLB entry will have no effect.</p> <p>³ [Category: Embedded.Little-Endian]</p> <p>⁴ Support for these attributes is optional.</p> <p>⁵ [Category: VLE]</p> <p>⁶ [Category: SAO] The combination WIMG = 0b1110 has behavior unrelated to the meanings of the individual bits. See Section 6.8.3.1, "Storage Control Bit Restrictions" for additional information.</p> <p>⁷ The coherency method used in Alternate Coherency Mode is implementation-dependent.</p>	

Figure 25. Storage control bits

In Section 6.8.3.1 and 6.8.3.2, "access" includes accesses that are performed out-of-order.

Programming Note

In a system consisting of only a single-threaded processor that has caches, correct coherent execution does not require storage to be accessed as Memory Coherence Required, and accessing storage as not Memory Coherence Required may give better performance.

6.8.3.1 Storage Control Bit Restrictions

All combinations of W, I, M, G, and E values are permitted except those for which both W and I are 1 and MIIG ≠ 0b10.

The combination WIMG = 0b1110 is used to identify the Strong Access Ordering (SAO) storage attribute (see Section 1.7.1, "Storage Access Ordering", in Book II). Because this attribute is not intended for general purpose programming, it is provided only for a single combination of the attributes normally identified using the WIMG bits. That combination would normally be indicated by WIMG = 0b0010.

References to Caching Inhibited storage (or storage with I=1) elsewhere in the Power ISA have no application to SAO storage or its WIMG encoding, despite the fact that the encoding uses using I=1. Conversely, references to storage that is not Caching Inhibited (or storage with I=0) apply to SAO storage or its WIMG encoding. References to Write Through Required storage (or storage with W=1) elsewhere in the Power ISA have no application to SAO storage or its WIMG encoding, despite the encoding using W=1. Conversely, references to storage that is not Write Through Required (or storage with W=0) apply to SAO storage or its WIMG encoding.

If a given real page is accessed concurrently as SAO storage and as non-SAO storage, the result may be characteristic of the weakly consistent model.

Programming Note

If an application program requests both the Write Through Required and the Caching Inhibited attributes for a given storage location, the operating system should set the I bit to 1 and the W bit to 0. For implementations that support the SAO category, the operating system should provide a means by which application programs can request SAO storage, in order to avoid confusion with the preceding guideline (since SAO is encoded using WI=0b11).

Accesses to the same storage location using two effective addresses for which the W bit differs meet the memory coherence requirements described in Section 1.6.3 of Book II if the accesses are performed by a single thread. If the accesses are performed by two or more threads, coherence is enforced by the hardware only if the W bit is the same for all the accesses.

At any given time, the value of the I bit must be the same for all accesses to a given real page.

At any given time, data accesses to a given real page may use both Endian modes. When changing the Endian mode of a given real page for instruction fetching, care must be taken to prevent accesses while the change is made and to flush the instruction cache(s) after the change has been completed.

Setting the VLE attribute to 1 and setting the E attribute to 1 is considered a programming error and an attempt to fetch instructions from a page so marked produces an Instruction Storage Interrupt Byte Ordering Excep-

tion and sets ESR_{BO} or $GESR_{BO}$ to 1 ($GESR_{BO}$ if the Embedded.Hypervisor category is supported and the interrupt is directed to the guest. Otherwise, ESR_{BO}).

At any given time, the value of the VLE bit must be the same for all accesses to a given real page.

Programming Note

When changing the Endian mode of a given real page used for instruction fetching and the instruction cache is shared between threads, care must be taken to prevent accesses from any thread that shares the instruction cache while the change is made until the instruction cache flush has been completed.

When changing the value of the VLE bit for a given real page, software must set the VLE bit to the new value, then, if the page was not Caching Inhibited, invalidate copies of all locations in the page from instruction cache using *icbi* or *icbiep*, and then execute an *isync* instruction before permitting any other accesses to the page.

6.8.3.2 Altering the Storage Control Bits

When changing the value of the W bit for a given real page from 0 to 1, software must ensure that no thread modifies any location in the page until after all copies of locations in the page that are considered to be modified in the data caches have been copied to main storage using *dcbst*, *dcbstep*, *dcbf*, *dcbfep*, or *dcbi*.

When changing the value of the I bit for a given real page from 0 to 1, software must set the I bit to 1 and then flush all copies of locations in the page from the caches using *dcbf*, *dcbfep*, or *dcbi*, and *icbi* or *icbiep* before permitting any other accesses to the page.

Programming Note

The storage control bit alterations described above are examples of cases in which the directives for application of statements about the W and I bits to SAO given in the third paragraph of the preceding subsection must be applied. A transition from the typical $WIMG=0b0010$ for ordinary storage to $WIMG=0b1110$ for SAO storage does not require the flush described above because both $WIMG$ combinations indicate storage that is not Caching Inhibited.

When changing the value of the M bit for a given real page, software must ensure that all data caches are consistent with main storage. The actions required to do this to are system-dependent.

Programming Note

For example, when changing the M bit in some directory-based systems, software may be required to execute *dcbf* or *dcbfep* on each thread to flush all storage locations accessed with the old M value before permitting the locations to be accessed with the new M value.

The actions required when changing the ACM bit for a given real page are system-dependent.

Programming Note

This Note suggests one example for managing reference and change recording.

When performing physical page management, it is useful to know whether a given physical page has been referenced or altered. Note that this may be more involved than knowing whether a given TLB entry has been used to reference or alter memory, since multiple TLB entries may translate to the same physical page. If it is necessary to replace the contents of some physical page with other contents, a page which has been referenced (accessed for any purpose) is more likely to be retained than a page which has never been referenced. If the contents of a given physical page are to be replaced, then the contents of that page must be written to the backing store before replacement, if anything in that page has been changed. Software must maintain records to control this process.

Similarly, when performing TLB management, it is useful to know whether a given TLB entry has been referenced. When making a decision about which entry to cast-out of the TLB, an entry which has been referenced is more likely to be retained in the TLB than an entry which has never been referenced.

Execute, Read and Write Access Control exceptions may be used to allow software to maintain reference information for a TLB entry and for its associated physical page. The entry is built, with its UX, SX, UR, SR,

UW, and SW bits off, and the index and effective page number of the entry retained by software. The first attempt of application code to use the page will cause an Access Control exception (because the entry is marked “No Execute”, “No Read”, and “No Write”). The Instruction or Data Storage interrupt handler records the reference to the TLB entry and to the associated physical page in a software table, and then turns on the appropriate access control bit. An initial read from the page could be handled by only turning on the appropriate UR or SR access control bits, leaving the page “read-only”.

In a demand-paged environment, when the contents of a physical page are to be replaced, if any storage in that physical page has been altered, then the backing storage must be updated. The information that a physical page is dirty is typically recorded in a “Change” bit for that page.

Write Access Control exceptions may be used to allow software to maintain change information for a physical page. For the example just given for reference recording, the first write access to the page via the TLB entry will create a Write Access Control exception type Data Storage interrupt. The Data Storage interrupt handler records the change status to the physical page in a software table, and then turns on the appropriate UW and SW bits.

6.9 Logical to Real Address Translation [Category: Embedded.Hypervisor.LRAT]

In a partitioned environment, a guest operating system is not allowed to manipulate real page numbers. Instead the hypervisor virtualizes the real memory and the guest operating system manages the virtualized memory using logical page numbers (LPNs). In MMU Architecture Version 2.0, a Logical to Real Address Translation (LRAT) array facilitates this virtualization by providing a hardware translation from an LPN to an RPN without trapping to the hypervisor for every TLB update.

LRAT Entry

Below are shown the field definitions for an LRAT entry.

Name	Description
V	<p>Valid</p> <p>This bit indicates that this LRAT entry is valid and may be used for translation of an LPN to an RPN. The Valid bit for a given entry can be set or cleared with a tlbwe instruction.</p>
LPID	<p>Logical Partition ID</p> <p>This optional field identifies a partition. The Logical Partition ID is compared with LPIDR contents during an LRAT translation. This field is required if category E.PT is supported or if threads that share an LRAT can be in different partitions. Whether the LPID field is supported is indicated by LRATCFG_{LPID}.</p> <p>Note: The number of bits implemented for this field is required to be the same as the TLPID field in a TLB.</p>
LPN	<p>Logical Page Number (up to 54 bits)</p> <p>Bits 64-<i>q</i>:<i>n</i>-1 of the LPN field are compared to bits 64-<i>q</i>:<i>n</i>-1 of the Logical Page Number (LPN) for the tlbwe instruction or Page Table translation (where <i>q</i> = LRATCFG_{LSIZE} and <i>n</i> = 64 - log₂(<i>logical page size</i> in bytes) and <i>logical page size</i> is specified by the LSIZE field of the LRAT entry). See Section 6.7.2. Software must set unused low-order LPN bits to 0.</p> <p>Note: Bits X:Y of the LPN field are implemented, where X ≥ 0 and Y ≤ 53. The bits implemented for LPN are not required to be the same as those implemented for TLB_{RPN}. Unimplemented LRPN bits are treated as if they contain 0s.</p>

LSIZE Logical Page Size

The LSIZE field specifies the size of the logical page associated with the LRAT entry as $2^{\text{LSIZE}}\text{KB}$, where $0 \leq \text{LSIZE} \leq 31$. Implementations may support any one or more of these logical page sizes (see Section 6.10.3.6), and these logical page sizes need not be the same as the real page sizes that are implemented. However, the smallest logical page is no smaller than the smallest real page. The encodes for LSIZE are the same as the encodes for the TLB SIZE. See Section 6.7.2. This field must be one of the logical pages sizes specified by the LRATPS register.

LRPN LRAT Real Page Number (up to 54 bits)

Bits 0:*n*-1 of the LRPN field are used to replace bits 0:*n*-1 of the LPN to produce the RPN that is written to TLB_{RPN} by a **tlbwe** instruction or a Page Table translation (where *n*=64-log₂(*logical page size* in bytes) and *logical page size* is specified by the LSIZE field of the LRAT entry). Software must set unused low-order LRPN bits to 0.

Note: Bits X:Y of the LRPN field are implemented, where X ≥ 0 and Y ≤ 53. X = 64 - MMUCFG_{RASIZE}. Y = p - 1 where p = 64 - log₂(*smallest logical page size* in bytes) and *smallest logical page size* is the smallest page size supported by the implementation as specified by the LRATPS register. Unimplemented LRPN bits are treated as if they contain 0s.

An LRAT entry can be written by the hypervisor using the **tlbwe** instruction with MAS0_{ATSEL} equal to 1. The contents of the LRAT entry specified by MAS0_{ESEL}, and MAS2_{EPN} are written from MAS registers. See the **tlbwe** instruction description in Section 6.11.4.9.

An LRAT entry can be read by the hypervisor using the **tlbre** instruction with MAS0_{ATSEL} equal to 1. The contents of the LRAT entry specified by MAS0_{ESEL} and MAS2_{EPN} are read and placed into the MAS registers. See the **tlbre** instruction description in Section 6.11.4.9.

Maintenance of LRAT entries is under hypervisor software control. Hypervisor software determines LRAT entry replacement strategy. There is no Next Victim support for the LRAT array.

The LRAT array is a hypervisor resource.

There is at most one LRAT array per thread.

Programming Note

Hypervisor software should not create an LRAT entry that maps any real memory regions for which a TLB entry should have VF equal to 1. Otherwise, a guest operating system could incorrectly create TLB entries, for this memory, with VF=0, assuming hypervisor software normally sets MAS8_{VF}=0 before giving control to a guest operating system.

TLB Write

When the guest operating system manipulates the values of RPN fields of MAS registers, the values are treated as forming an LPN. When guest supervisor software attempts to execute **tlbwe** on an implementation that supports MMU Architecture Version 1, **tlbre**, and **tlbsx**, which operate on a TLB entry's real page number (RPN) or when guest supervisor software attempts to execute a **TLB Management** instruction with guest execution of **TLB Management** instructions disabled (EPCR_{DGTMI}=1), an Embedded Hypervisor Privilege exception occurs. Also, if TLBnCFG_{GTWE} = 0 for a TLB array and the guest supervisor executes a **tlbwe** to the TLB array, an Embedded Hypervisor Privilege exception occurs. If a **tlbwe** caused the exception, the hypervisor can replace the LPN value in the MAS registers with the corresponding RPN, execute a **tlbwe**, and restore the LPN in the MAS registers before returning to the guest operating system. If a **tlbre** or **tlbsx** caused the exception, the hypervisor can execute the exception-causing instruction and replace the RPN value in the MAS registers with the corresponding LPN before returning to the guest operating system.

A Logical to Real Address Translation (LRAT) array provides a mechanism that allows a guest operating system to write the TLB without trapping to the hypervisor. When guest supervisor software executes **tlbwe** on an implementation that supports MMU Architecture Version 2, guest execution of **TLB Management** instructions is enabled (EPCR_{DGTMI}=0), and TLBnCFG_{GTWE} = 1 for the TLB array to be written, an LPN is formed. If MAS7 is implemented, LPN = MAS7_{RPNU} || MAS3_{RPNL}. Otherwise, LPN = ³²0 || MAS3_{RPNL}. The LPN is translated into an RPN by the LRAT if a matching LRAT entry is found. A matching LRAT entry exists if the following conditions are all true for some LRAT entry.

- The Valid bit of the LRAT entry is one.
- Either the LPID field is not supported in the LRAT (LRATCFG_{LPID}=0) or the value of LPIDR_{LPID} is equal to the value of the LPID field of the LRAT entry.
- Bits 64-q:n-1 of the LPN match the corresponding bits of the LPN field of the LRAT entry where $n = 64 - \log_2(\text{logical page size in bytes})$, *logical page size* is specified by the LSIZE field of the LRAT entry, and q is specified by LRATCFG_{LASIZE}.
- Either of the following is true.

- MAS1_{IND} = 0 and the value of MAS1_{TSIZE} is less than or equal to the value of the LSIZE field of the LRAT entry.
- MAS1_{IND} = 1 and the value of (3 + (MAS1_{TSIZE} - MAS3_{SPSIZE})) is less than or equal to the value of the (10 + LRAT entry_{LSIZE}).

If a matching LRAT entry is found, the LRPN from that LRAT entry provides the upper bits of the RPN that is written to the TLB, and the LPN provides the low order RPN bits written to the TLB. Let $n=64 - \log_2(\text{logical page size in bytes})$ where *logical page size* is specified by the LSIZE field of the LRAT entry. Bits n:53 of the LPN are appended to bits 0:n-1 of the LRPN field of the selected LRAT entry to produce the RPN (i.e. RPN = LRPN_{0:n-1} || LPN_{n:53}). The page size specified by the LSIZE of the LRAT entry used to translate the LPN must be one of the values supported by the implementation's LRAT array. If the LRAT does not contain a matching entry for the LPN, an LRAT Miss exception occurs.

When the hypervisor executes a **tlbwe** instruction, no LRAT translation is performed and the RPN formed from MAS7_{RPNU} and MAS3_{RPNL} is written to the TLB.

Page Table

A Logical to Real Address Translation (LRAT) array provides a mechanism that allows guest Page Table management and translation without direct hypervisor involvement. When an instruction fetch address or a *Load, Store, or Cache Management* instruction operand address is translated by the Page Table, the Embedded.Hypervisor category is supported, and the TGS bit of the associated indirect TLB entry is 1, the RPN result of the Page Table translation is treated as an LPN that is translated into an RPN by the LRAT if a matching LRAT entry is found. A matching LRAT entry exists if the following conditions are all true for some LRAT entry.

- The Valid bit of the LRAT entry is one.
- Either the LPID field is not supported in the LRAT (LRATCFG_{LPID}=0) or the value of LPIDR_{LPID} is equal to the value of the LPID field of the LRAT entry.
- Bits 64-q:n-1 of the LPN match the corresponding bits of the LPN field of the LRAT entry where $n = 64 - \log_2(\text{logical page size in bytes})$, *logical page size* is specified by the LSIZE field of the LRAT entry, and q is specified by LRATCFG_{LASIZE}.
- The value of PTE_{PS} is less than or equal to the value of the LSIZE field of the LRAT entry.

If a matching LRAT entry is found, the LRPN from that LRAT entry provides the upper bits of the RPN of the translation result and the LPN provides the low order RPN bits of the translation result. Let $n=64 - \log_2(\text{logical page size in bytes})$ where *logical page size* is specified by the LSIZE field of the LRAT entry. Bits

$n:51$ of the LPN are appended to bits $0:n-1$ of the LRPN field of the selected LRAT entry to produce the RPN (i.e. $RPN = LRPN_{0:n-1} \parallel LPN_{n:51}$). The page size specified by the LSIZE of the LRAT entry used to translate the LPN must be one of the values supported by the implementation's LRAT array. If the LRAT does not contain a matching entry for the LPN, an LRAT Miss exception occurs.

6.10 Storage Control Registers

In addition to the registers described below, the Machine State Register provides the IS and DS bits, that specify which of the two address spaces the respective instruction or data storage accesses are directed towards. MSR_{PR} bit is also used by the storage access control mechanism. If the Embedded.Hypervisor category is supported, the MSR_{GS} bit is used to identify guest state. The guest supervisor state exists when $MSR_{PR} = 0$ and $MSR_{GS} = 1$. MSR_{GS} is used to form the virtual address. Also, see Section 5.3.6 for the registers in the Embedded.External PID category.

6.10.1 Process ID Register

The Process ID Registers are 32-bit registers as shown in Figure 26. Process ID Register bits are numbered 32 (most-significant bit) to 63 (least-significant bit). The number of bits implemented in a PID register is indicated by the value of the $MMUCFG_{PIDSIZE}$. The Process ID Register provides a value that is used to construct a virtual address for accessing storage.

The Process ID Register is a privileged register. This register can be read using *mtspr* and can be written using *mtspr*. An implementation may opt to implement only the least-significant n bits of the Process ID Register, where $1 \leq n \leq 14$, and n must be the same as the number of implemented bits in the TID field of the TLB entry. The most-significant $32-n$ bits of the Process ID Register are treated as reserved.

Figure 26. Processor ID Register (PID)

The PID register fields are described below.

Bit	Description
50:63	Processor ID (PID) Identifies a unique process (except for the value of 0) and is used to construct a virtual address for storage accesses.

All other fields are reserved.

Programming Note

The PID register was referred to as PID0 in the Type FSL Storage Control appendix of previous versions of the architecture.

6.10.2 MMU Assist Registers

The MMU Assist Registers (MAS) are used to transfer data to and from the TLB arrays. If the Embedded.Hypervisor.LRAT category is supported, MAS registers are also used to transfer data to and from the LRAT array. MAS registers can be read and written by software using *mfspir* and *mtspir* instructions. Execution of a *tlbre* instruction with $MAS0_{ATSEL}=0$ causes the TLB entry specified by $MAS0_{TLBSEL}$, $MAS0_{ESEL}$, and $MAS2_{EPN}$ to be copied to the MAS registers if $TLBnCFG_{HES} = 0$ for the TLB array specified by $MAS0_{TLBSEL}$ whereas the TLB entry is specified by $MAS0_{ESEL}$, $MAS0_{TLBSEL}$, and a hardware generated hash based on $MAS2_{EPN}$, $MAS1_{TID}$, and $MAS1_{TSIZE}$ if $TLBnCFG_{HES}=1$. Execution of a *tlbwe* instruction with $MAS0_{ATSEL}=0$ (or in hypervisor state) causes the TLB entry specified by $MAS0_{TLBSEL}$, $MAS0_{ESEL}$, and $MAS2_{EPN}$ to be written with contents of the MAS registers if $TLBnCFG_{HES} = 0$ for the TLB array specified by $MAS0_{TLBSEL}$. If $TLBnCFG_{HES} = 1$ for a *tlbwe*, the TLB entry is selected by $MAS0_{TLBSEL}$, a hardware generated hash based on $MAS2_{EPN}$, $MAS1_{TID}$, and $MAS1_{TSIZE}$, and either a hardware replacement algorithm if $MAS0_{HES}=1$ or $MAS0_{ESEL}$ if $MAS0_{HES}=0$. MAS registers may also be updated by hardware as the result of any of the following.

- a *tlbsx* instruction
- the occurrence of an Instruction or Data TLB Error interrupt if any of the following is true.
 - The Embedded.Hypervisor category is not supported.
 - MAS Register updates are enabled for interrupts directed to the hypervisor ($EPCR_{DMIUH} = 0$).
 - The interrupt is directed to the guest state ($EPCR_{ITLBGS} = 1$ for Instruction TLB Error interrupt and $EPCR_{DTLBGS} = 1$ for Data TLB Error interrupt).

All MAS registers are privileged, except MAS5 and MAS8, which are hypervisor privileged and are only provided if category Embedded.Hypervisor is supported. All MAS registers with the exception of MAS7 and, if Embedded.Hypervisor category is not supported, MAS5 and MAS8, must be implemented. MAS7 is not required to be implemented if the hardware supports 32 bits or less of real address.

The necessary bits of any multi-bit field in a MAS register must be implemented such that only the resources supported are represented. Any non-implemented bits in a field should have no effect when writing and should always read as zero. For example, if only 2 TLB arrays

are implemented, then only the lower-order bit of the $MAS0_{TLBSEL}$ field is implemented.

6.10.3 MMU Configuration and Control Registers

6.10.3.1 MMU Configuration Register (MMUCFG)

The read-only MMUCFG register provides information about the MMU and its arrays. MMUCFG is a privileged register except that if the Embedded.Hypervisor category is supported, MMUCFG is a hypervisor resource. The layout of the MMUCFG register is shown in Figure 27 for MAV=1.0 and in Figure 28 for MAV=2.0.

Figure 27. MMU Configuration Register [MAV=1.0]

Figure 28. MMU Configuration Register [MAV=2.0]

The MMUCFG fields are described below.

Bit	Description
36:39	LPID Register Size (LPIDSIZE) The value of LPIDSIZE is the number of bits in LPIDR that are implemented. Only the least significant LPIDSIZE bits in LPIDR are implemented. The Embedded.Hypervisor category is supported if and only if LPIDSIZE > 0.
40:46	Real Address Size (RASIZE) Number of bits in a real address supported by the implementation.
47	LRAT Translation Supported (LRAT) [Category: Embedded.Hypervisor.LRAT] Indicates LRAT translation is supported. 0 LRAT translation is not supported. A <i>tlbwe</i> executed in guest supervisor state results in an Embedded Hypervisor Privilege exception. 1 LRAT translation is supported by one or more TLB arrays. See $TLBnCFG_{GTWE}$. The LRATCFG and LRATPS registers are supported.
48	TLB Write Conditional (TWC) [MAV=2.0] Indicates whether the Embedded.TLB Write Conditional category is supported.

- 0 E.TWC category is not supported
- 1 E.TWC category is supported. See Section 6.11.4.2.1 for a description of conditional TLB writes. This category also includes support for the *tlbsrx*. instruction, $MAS0_{WQ}$, and $MAS6_{ISIZE}$.

- 53:57 **PID Register Size** (PIDSIZE)
The value of PIDSIZE is one less than the number of bits implemented for each of the PID registers implemented. Only the least significant PIDSIZE+1 bits in the PID registers are implemented. The maximum number of PID register bits that may be implemented is 14.
- 60:61 **Number of TLBs** (NTLBS)
The value of NTLBS is one less than the number of software-accessible TLB structures that are implemented. NTLBS is set to one less than the number of TLB structures so that its value matches the maximum value of $MAS0_{TLBSEL}$.
- 00 1 TLB
 - 01 2 TLBs
 - 10 3 TLBs
 - 11 4 TLBs
- 62:63 **MMU Architecture Version Number** (MAVN)
Indicates the version number of the architecture of the MMU implemented.
- 00 Version 1.0
 - 01 Version 2.0
 - 10 Reserved
 - 11 Reserved

All other fields are reserved.

6.10.3.2 TLB Configuration Registers (TLBnCFG)

Each $TLBnCFG$ read-only register provides configuration information about each corresponding TLB array that is implemented. There is one $TLBnCFG$ register implemented for each TLB array that is implemented. $TLBnCFG$ corresponds to $TLBn$ for $0 \leq n \leq MMUCFG_{NTLBS}$. $TLBnCFG$ registers are privileged registers except that if the Embedded.Hypervisor category is supported, $TLBnCFG$ registers are hypervisor resources. The layout of the $TLBnCFG$ registers is

shown in Figure 29 for MAV=1.0 and in Figure 30 for MAV=2.0.

Figure 29. TLB Configuration Register [MAV=1.0]

Figure 30. TLB Configuration Register [MAV=2.0]

The TLB_nCFG fields are described below.

Bit	Description
32:39	Associativity (ASSOC) Total number of entries in a TLB array which can be used for translating addresses with a given EPN. This number is referred to as the associativity level of the TLB array. A value equal to NENTRY or 0 indicates the array is fully-associative.
40:43	Minimum Page Size (MINSIZE) [MAV=1.0] This field defines the minimum page size of the TLB array. Page size encoding is defined in Section 6.7.2.
44:47	Maximum Page Size (MAXSIZE) [MAV=1.0] This field defines the maximum page size of the TLB array. Page size encoding is defined in Section 6.7.2.
45	Page Table (PT) [MAV=2.0 and Category: E.PT] Indicates that the TLB array can be loaded from the hardware Page Table. 0 TLB array cannot be loaded from the Page Table. 1 TLB array can be loaded from the Page Table.
46	Indirect (IND) [MAV=2.0 and Category: E.PT] Indicates that an indirect TLB entry can be created in the TLB array and that there is a corresponding EPTCFG register that defines the SIZE and Sub-Page Size values that are supported. 0 The TLB array treats the IND bit as reserved. 1 The TLB array supports indirect entries.
47	Guest TLB Write Enabled (GTWE) [MAV=2.0 and Category: Embedded.Hypervisor.LRAT] Indicates that a guest supervisor can write the

TLB array because LRAT translation is supported for the TLB array.

- 0 A guest supervisor cannot write the TLB array. A *tlbwe* executed in guest supervisor state results in an Embedded Hypervisor Privilege exception.
- 1 A guest supervisor can write the TLB array if guest execution of *TLB Management* instructions is enabled (EPCR_{DGTM}=0).
- 48 **Invalidate Protection** (IPROT)
Invalidate protect capability of the TLB array.
0 Indicates invalidate protection capability not supported.
1 Indicates invalidate protection capability supported.
- 49 **Page Size Availability** (AVAIL) [MAV=1.0]
This defines the page size availability of the TLB array. If the Embedded.Page Table category is supported, this also defines the virtual address space size availability of TLB array. Otherwise, this field is reserved.
0 Fixed selectable page size from MINSIZE to MAXSIZE (all TLB entries are the same size).
1 Variable page size from MINSIZE to MAXSIZE (each TLB entry can be sized separately).
- 50 **Hardware Entry Select** (HES) [MAV=2.0]
Indicates whether the TLB array supports MAS_{0HES} and the associated method for hardware selecting a TLB entry based on MAS_{1TID} TSIZE and MAS_{2EPN} for a *tlbwe* instruction.
0 MAS_{0HES} is not supported.
1 MAS_{0HES} is supported for *tlbwe*. See Section 6.10.3.8. For *tlbre*, MAS_{0ESEL} selects among the TLB entries that can be used for translating addresses with a given MAS_{1TID} TSIZE and MAS_{2EPN}. The set of TLB entries is determined by a hardware generated hash based on MAS_{1TID} TSIZE and MAS_{2EPN}. The hash is the same for *tlbwe* and *tlbre* for a given TLB array but could be different for each TLB array.
- 52:63 **Number of Entries** (NENTRY)
Number of entries in the TLB array.

All other fields are reserved.

6.10.3.3 TLB Page Size Registers (TLB_nPS) [MAV=2.0]

Each TLB_nPS read-only register provides page size information about each corresponding TLB array that is implemented in MMU Architecture Version 2.0. Each

Page Size bit (PS0-PS31) that is a one indicates that a specific page size is supported by the array. Multiple 1 bits indicate that multiple page sizes are supported concurrently. TLB n PS registers are privileged registers except that if the Embedded.Hypervisor category is supported, TLB n PS registers are hypervisor resources. The layout of the TLB n PS registers is shown in Figure 31.

Figure 31. TLB n Page Size Register

The TLB n PS fields are described below.

Bit	Description
32:63	Page Size 31 - Page Size 0 (PS31-PS0) PS m indicates whether a direct TLB entry page size of 2^m KB is supported by the TLB array. PS m corresponds to bit TLB n PS $_{63-m}$ for $m = 0$ to 31.
0	Direct TLB entry page size of 2^m KB is not supported.
1	Direct TLB entry page size of 2^m KB is supported.

Table 9 shows the relationship between the Page Size (PS m) bits in TLB n PS and page size. The existence and type of mechanism for configuring the use of a subset of supported page sizes is implementation-dependent.

Table 9: Relationship of TLB n PS PS bits and LRATPS PS bits to page size

TLB n PS or LRATPS bit	PS m	Page Size
32	PS31	2TB
33	PS30	1TB
34	PS29	512GB
35	PS28	256GB
36	PS27	128GB
37	PS26	64GB
38	PS25	32GB
39	PS24	16GB
40	PS23	8GB
41	PS22	4GB
42	PS21	2GB
43	PS20	1GB
44	PS19	512MB
45	PS18	256MB
46	PS17	128MB
47	PS16	64MB
48	PS15	32MB
49	PS14	16MB
50	PS13	8mb
51	PS12	4MB
52	PS11	2MB
53	PS10	1MB
54	PS9	512KB
55	PS8	256KB
56	PS7	128KB
57	PS6	64KB
58	PS5	32KB
59	PS4	16KB
60	PS3	8KB
61	PS2	4KB
62	PS1	2KB
63	PS0	1KB

6.10.3.4 Embedded Page Table Configuration Register (EPTCFG)

This read-only register consists of 3 pairs of page size (PS i) and sub-page size (SPS i) values, where $i = 0$ to 2. These combinations are supported for Page Table translations. The page size and sub-page size encodings for PS i and SPS i are the same the MAS1 $_T$ SIZE encodings, except that an SPS i value of 0b00001 is reserved and a value of zero for the SPS i field means there is no page size and sub-page size combination information supplied by that field. If SPS i is zero, PS i is zero. Zero values of PS i and SPS i pairs are the left-most fields. See Table 3. For nonzero values of SPS i , PS i minus SPS i is greater than 7.

The EPTCFG register is a privileged register except that if the Embedded.Hypervisor category is supported,

EPTCFG register is a hypervisor resource. The layout of the EPTCFG register is shown in Figure 32.

//	PS2	SPS2	PS1	SPS1	PS0	SPS0
32 34	39	44	49	54	59	63

Figure 32. Embedded Page Table Configuration Register

The EPTCFG fields are described below.

Bit	Description
34:38	Page Size 2 (PS2) PS2 indicates whether an indirect TLB entry with a page size of 2^{PS2} KB combined with the sub-page size specified by SPS2 is supported.
39:43	Sub-Page Size 2 (SPS2) SPS2 indicates whether an indirect TLB entry with a sub-page size of 2^{SPS2} KB combined with the page size specified by PS2 is supported.
44:48	Page Size 1 (PS1) PS1 indicates whether an indirect TLB entry with a page size of 2^{PS1} KB combined with the sub-page size specified by SPS1 is supported.
49:53	Sub-Page Size 1 (SPS1) SPS1 indicates whether an indirect TLB entry with a sub-page size of 2^{SPS1} KB combined with the page size specified by PS1 is supported.
54:58	Page Size 0 (PS0) PS0 indicates whether an indirect TLB entry with a page size of 2^{PS0} KB combined with the sub-page size specified by SPS0 is supported.
59:63	Sub-Page Size 0 (SPS0) SPS0 indicates whether an indirect TLB entry with a sub-page size of 2^{SPS0} KB combined with the page size specified by PS0 is supported.

6.10.3.5 LRAT Configuration Register (LRATCFG) [Category: Embedded.Hypervisor.LRAT]

The LRATCFG read-only register provides configuration information about the LRAT array. LRATCFG is a hypervisor resource. The layout of the LRATCFG registers is shown in Figure 33.

ASSOC	LASIZE	///	 /	NENTRY
32	40	47	50 51 52	63

Figure 33. LRAT Configuration Register

The LRATCFG fields are described below.

Bit	Description
32:39	Associativity (ASSOC) Total number of entries in the LRAT array which can be used for translating addresses with a given EPN. This number is referred to as the associativity level of the LRAT array. A value equal to NENTRY or 0 indicates the array is fully-associative.
40:46	Logical Address Size (LASIZE) Number of bits in a logical address supported by the implementation.
50	LPID Supported (LPID) Indicates whether the LPID field in the LRAT is supported. 0 The LPID field in the LRAT is not supported. 1 The LPID field in the LRAT is supported.
52:63	Number of Entries (NENTRY) Number of entries in LRAT array. At least one entry is supported.

All other fields are reserved.

6.10.3.6 LRAT Page Size Register (LRATPS) [Category: Embedded.Hypervisor.LRAT]

LRATPS is a read-only register that provides page size information about the LRAT that is implemented if the Embedded.Hypervisor.LRAT category is supported in MMU Architecture Version 2.0. Each Page Size bit (PS0-PS31) that is a one indicates that a specific logical page size is supported by the array. Multiple 1 bits indicate that multiple page sizes are supported concurrently. LRATPS is a hypervisor resource. The layout of the LRATPS registers is shown in Figure 34.

PS31 - PS0	
32	63

Figure 34. LRAT Page Size Register

The LRATPS fields are described below.

Bit	Description
32:63	Page Size 31 - Page Size 0 (PS31-PS0) PS _m indicates whether a logical page size of 2^m KB is supported by the LRAT array. PS _m corresponds to bit LRATPS _{64-m} for $m = 0$ to 31. 0 Logical page size of 2^m KB is not supported. 1 Logical page size of 2^m KB is supported.

All other fields are reserved.

Table 9 on page 976 shows the relationship between the Page Size (PS_m) bits in LRATPS and the logical page size.

6.10.3.7 MMU Control and Status Register (MMUCSR0)

The MMUCSR0 register is used for general control of the MMU including page sizes for programmable fixed size TLB arrays [MAV=1.0] and invalidation of the TLB array. For TLB arrays that have programmable fixed sizes, the TLB_n_PS fields [MAV=1.0] allow software to specify the page size. MMUCSR0 is a privileged register except that if the Embedded.Hypervisor category is supported, MMUCSR0 is a hypervisor resource.

The layout of the MMUCSR0 is shown in Figure 35 for MAV=1.0 and in Figure 36 for MAV=2.0.

Figure 35. MMU Control and Status Register 0 [MAV=1.0]

Figure 36. MMU Control and Status Register 0 [MAV=2.0]

The MMUCSR0 fields are described below.

Bit Description

41:56 **TLB_n Array Page Size** [MAV=1.0]
A 4-bit field specifies the page size for TLB_n array. Page size encoding is defined in Section 6.7.2. If the value of TLB_n_PS is not between TLB_nCFG_{MIN}SIZE and TLB_nCFG_{MAX}SIZE, the page size is set to TLB_nCFG_{MIN}SIZE. A TLB_n_PS field is implemented only for a TLB array that can be programmed to support only one of several fixed page sizes. For each TLB array *n* (for $0 \leq n < \text{MMUCFG}_{\text{NTLBS}}$), this field is implemented only if the following are all true.

- TLB_nCFG_{AVAIL} = 0.
- TLB_nCFG_{MIN}SIZE ≠ TLB_nCFG_{MAX}SIZE.

Bit Description

41:44 **TLB3 Array Page Size** (TLB3_PS)
Page size of the TLB3 array.
45:48 **TLB2 Array Page Size** (TLB2_PS)
Page size of the TLB2 array.
49:52 **TLB1 Array Page Size** (TLB1_PS)
Page size of the TLB1 array.
53:56 **TLB0 Array Page Size** (TLB0_PS)
Page size of the TLB0 array.

Programming Note

Changing the fixed page size of an entire array must be done with great care. If any entries in the array are valid, changing the page size may cause those entries to overlap, creating a serious programming error. It is suggested that the entire TLB array be invalidated and any entries with IPROT have their V bits set to zero before changing page size.

- 57:62 **TLB_n Invalidate All**
TLB invalidate all bit for the TLB_n array.
- 0 If this bit reads as a 1, an invalidate all operation for the TLB_n array is in progress. Hardware will set this bit to 0 when the invalidate all operation is completed. Writing a 0 to this bit during an invalidate all operation is ignored.
- 1 TLB_n invalidation operation. Hardware initiates a TLB_n invalidate all operation. When this operation is complete, this bit is cleared. Writing a 1 during an invalidate all operation produces an undefined result. If the TLB array supports IPROT, entries that have IPROT set will not be invalidated.
- 57 **TLB2 Invalidate All** (TLB2_FI)
TLB invalidate all bit for the TLB2 array.
- 58 **TLB3 Invalidate All** (TLB3_FI)
TLB invalidate all bit for the TLB3 array.
- 61 **TLB0 Invalidate All** (TLB0_FI)
TLB invalidate all bit for the TLB0 array.
- 62 **TLB1 Invalidate All** (TLB1_FI)
TLB invalidate all bit for the TLB1 array.

All other fields are reserved.

6.10.3.8 MAS0 Register

The MAS0 register contains fields for identifying and selecting a TLB entry. If the Embedded.Hypervisor.LRAT category is supported, the MAS0 register is also used to select an LRAT entry as well as select between a TLB array and the LRAT array. MAS0 register fields are loaded by the execution of the *tlbsx* instruction and by the occurrence of an Instruction or Data TLB Error interrupt under certain conditions.

MAS0 is a privileged register. The layout of the MAS0 register is shown in Figure 37.

Figure 37. MAS0 register

The MAS0 fields are described below.

Bit	Description
32	Array Type Select (ATSEL) [Category: Embedded.Hypervisor.LRAT] Selects LRAT or TLB for access for <i>tlbwe</i> and <i>tlbre</i> . In guest state, MAS0 _{ATSEL} is treated as if it were zero such that a TLB array is always selected.
	0 TLB 1 LRAT
34:35	TLB Select (TLBSEL) If ATSEL=0 or MSR _{GS} =1, selects TLB for access. If ATSEL=1, TLBSEL is treated as reserved.
	00 TLB0 01 TLB1 10 TLB2 11 TLB3
36:47	Entry Select (ESEL) Identifies an entry in the selected array to be used for <i>tlbwe</i> and <i>tlbre</i> . Valid values for ESEL are from 0 to TLBnCFG _{ASSOC} - 1 for a TLB array and 0 to LRATCFG _{ASSOC} - 1 for the LRAT. That is, ESEL selects the entry in the selected array from the set of entries which can be used for translating addresses with the EPN (if TLBnCFG _{HES} =0 and either MAS0 _{ATSEL} =0 or MSR _{GS} =1), the combination of EPN, SIZE, and PID (for <i>tlbwe</i> if TLBnCFG _{HES} =1 and either MAS0 _{ATSEL} =0 or MSR _{GS} =1), or the LPN (if MAS0 _{ATSEL} =1 and MSR _{GS} =0) specified by MAS2 _{EPN} . For fully-associative TLB or LRAT arrays, ESEL ranges from 0 to TLBnCFG _{NENTRY} - 1 or 0 to LRATCFG _{NENTRY} - 1, respectively.
49	Hardware Entry Select (HES) [MAV=2.0] Determines how the TLB entry within the selected TLB array is selected by <i>tlbwe</i> if a TLB entry is to be written (MAS0 _{ATSEL} =0 or MSR _{GS} =1). If an LRAT entry is to be written (MAS0 _{ATSEL} =1 and MSR _{GS} =0) by a <i>tlbwe</i> , HES must be 0. Otherwise the result is undefined. This field has no effect on other <i>TLB Management</i> instructions. Whether an implementation supports this bit for a TLB array is indicated by TLBnCFG _{HES} . If TLBnCFG _{HES} = 0, HES is ignored and treated as 0 for <i>tlbwe</i> .

- 0 The entry is selected by MAS0_{ESEL} and a hardware generated hash based on MAS1_{TID} *T*SIZE, and MAS2_{EPN}.
- 1 The entry is selected by a hardware replacement algorithm and a hardware generated hash based on MAS1_{TID} *T*SIZE, and MAS2_{EPN}.

- 50:51 **Write Qualifier (WQ)** [MAV=2.0 and Category: Embedded.TLB Write Conditional]
Qualifies the TLB write operation performed by *tlbwe* if a TLB entry is to be written (MAS0_{ATSEL}=0 or MSR_{GS}=1). If an LRAT entry is to be written (MAS0_{ATSEL}=1 and MSR_{GS}=0) by a *tlbwe* and the Embedded.TLB Write Conditional category is supported, WQ must be 0b00. Otherwise the result is undefined. This field has no effect on other *TLB Management* instructions. Whether an implementation supports this field is indicated by MMUCFG_{TWC}. If MMUCFG_{TWC} = 0, WQ is ignored and treated as 0b00 for *tlbwe*.
- 00 The selected TLB entry is written regardless of the TLB-reservation. The TLB-reservation is cleared.
 - 01 The selected TLB entry is written if and only if the TLB reservation exists. A *tlbwe* with this value is called a *TLB Write Conditional*. The TLB-reservation is cleared.
 - 10 The TLB-reservation is cleared; no TLB entry is written.
 - 11 Reserved

- 52:63 **Next Victim (NV)**
NV is a hint to software to identify the next victim to be targeted for a TLB miss replacement operation for those TLBs that support the NV function. If the TLB selected by MAS0_{TLBSEL} does not support the NV function, this field is undefined. The method of determining the next victim is implementation-dependent. NV is updated on *tlbsx* hit and miss cases as shown in Table 11 on page 986, on execution of *tlbre* if the TLB array being accessed supports the NV field, and on TLB Error interrupts if the Embedded.Hypervisor category is not supported, MAS Register updates are enabled for interrupts directed to the hypervisor (EPCR_{DMIUH} = 0), or the interrupt is directed to the guest state. When NV is updated by a supported TLB array, the NV field will always present a value that can be used in the MAS0_{ESEL} field. The LRAT array does not support Next Victim.

All other fields are reserved.

6.10.3.9 MAS1 Register

The MAS1 register contains fields used for reading and writing an LRAT <E.HV.LRAT> or TLB entry. MAS1

register fields are also loaded by the execution of the *tlbsx* instruction and by the occurrence of an Instruction or Data TLB Error interrupt under certain conditions. TLB fields loaded from the MAS1 register are used for selecting a TLB entry during translation. If the Embedded.Hypervisor.LRAT category is supported, LRAT fields V and LSIZE, which are loaded from MAS1_V TSIZE, are used for selecting an LRAT entry for translating LPNs when *tlbwe* is executed in guest supervisor state and, if the Embedded.Page Table category is supported, during page table lookups performed when the PTE_{ARPN} is treated as an LPN (The Embedded.Hypervisor.LRAT category is supported and the TGS bit of the corresponding indirect TLB entry is 1). MAS1 is a privileged register. The layout of the MAS1 register is shown in Figure 38 for MAV=1.0 and in Figure 39 for MAV=2.0.

Figure 38. MAS1 register [MAV=1.0]

Figure 39. MAS1 register [MAV=2.0]

The MAS1 fields are described below.

Bit	Definition
32	Valid Bit (V) See the corresponding TLB bit definition in Section 6.7.1 and the corresponding LRAT bit definition in Section 6.9.
33	Invalidate Protect (IPROT) See the corresponding TLB bit definition in Section 6.7.1.
34:47	Translation Identity (TID) See the corresponding TLB field definition in Section 6.7.1.
50	Indirect (IND) [MAV=2.0 and Category: Embedded.Page Table] See the corresponding TLB bit definition in Section 6.7.1.
51	Translation Space (TS) See the corresponding TLB bit definition in Section 6.7.1.
52:55	Translation Size (TSIZE) [MAV=1.0] See the TLB SIZE field definition in Section 6.7.1.
52:56	Translation Size (TSIZE) [MAV=2.0] See the TLB SIZE field definition in Section 6.7.1 and the LRAT LSIZE field definition in Section 6.9.

All other fields are reserved.

6.10.3.10 MAS2 Register

The MAS2 register is a 64-bit register in 64-bit implementations and a 32-bit register in 32-bit implementations. The MAS2 register contains fields used for reading and writing an LRAT <E.HV.LRAT> or TLB entry. MAS2 register fields are also loaded by the execution of the *tlbsx* instruction and by the occurrence of an Instruction or Data TLB Error interrupt under certain conditions. The register contains fields for specifying the effective page address and the storage control attributes for a TLB entry. If the Embedded.Hypervisor.LRAT category is supported, the MAS2 register EPN field can also be used for specifying the logical page number for an LRAT entry. The only MAS2 field used for the LRAT array is EPN. MAS2 is a privileged register. The layout of the MAS2 register is shown in Figure 40 for MAV=1.0 and in Figure 41 for MAV=2.0.

Figure 40. MAS2 register [MAV = 1.0]

Figure 41. MAS2 register [MAV = 2.0]

The MAS2 fields are described below.

Bit	Description
0:51	Effective Page Number (EPN) [MAV=1.0] See the corresponding TLB bit definition in Section 6.7.1. Bits that correspond to an offset within the smallest virtual page implemented need not be implemented. Unimplemented EPN bits are treated as 0s. EPN _{0:31} are implemented only in 64-bit implementations as the upper 32 bits of the effective address of the page.
0:53	Effective Page Number (EPN) [MAV=2.0] See the corresponding TLB bit definition in Section 6.7.1 and the LRAT LPN field definition in Section 6.9. Bits that correspond to an offset within the smallest virtual page implemented need not be implemented. Unimplemented EPN bits are treated as 0s. EPN _{0:31} are implemented only in 64-bit implementations as the upper 32 bits of the effective address of the page.
57	Alternate Coherency Mode (ACM) See the corresponding TLB bit definition in Section 6.7.1. If ACM is not supported by the implementation, this bit is treated as reserved.

Programming Note

Some previous implementations may have a TLB storage bit accessed via this bit position and labeled as X0. Software should not use the presence of this bit (the ability to set to 1 and read a 1) to determine if the implementation supports the Alternate Coherency Mode.

- 58 **VLE Mode (VLE)** [Category: VLE]
See the corresponding TLB bit definition in Section 6.7.1. If the VLE category is not supported, this bit is treated as reserved.

Programming Note

Some previous implementations may have a TLB storage bit accessed via this position and labeled as X1. Software should not use the presence of this bit (the ability to set to 1 and read a 1) to determine if the implementation supports the VLE.

- 59 **Write Through (W)**
See the corresponding TLB bit definition in Section 6.7.1.
- 60 **Caching Inhibited (I)**
See the corresponding TLB bit definition in Section 6.7.1.
- 61 **Memory Coherence Required (M)**
See the corresponding TLB bit definition in Section 6.7.1.
- 62 **Guarded (G)**
See the corresponding TLB bit definition in Section 6.7.1.
- 63 **Endianness (E)**
See the corresponding TLB bit definition in Section 6.7.1.

All other fields are reserved.

6.10.3.11 MAS3 Register

The MAS3 register contains fields used for reading and writing an LRAT <E.HV.LRAT> or TLB entry. MAS3 register fields are also loaded by the execution of the **tlbsx** instruction and by the occurrence of an Instruction or Data TLB Error interrupt under certain conditions. The MAS3 register contains fields for specifying the real page address, user defined attributes, and the permission attributes for a TLB entry. If the Embedded.Page Table category is supported, MAS3 also contains a field specifying the minimum page size specified by each Page Table Entry that is mapped by the indirect TLB entry. If the Embedded.Hypervisor.LRAT category is supported, the low-order LRPN bits of the LRAT array can be read into or written from MAS3_{RPNL} by hypervisor software. If the Embedded.Hypervisor.LRAT

category is supported, the RPN specified by MAS7 and MAS3 is treated as an LPN for **tlbwe** executed in guest supervisor state (see Section 6.9). MAS3 is a privileged register. If the Embedded.Page Table category is supported, MAS3 has different meanings depending on the MAS1_{IND} value. For MAS1_{IND} = 0, the layout of the MAS3 register is shown in Figure 42 for MAV=1.0 and in Figure 43 for MAV=2.0.

Figure 42. MAS3 register for MAS1_{IND}=0 [MAV=1.0]

Figure 43. MAS3 register for MAS1_{IND}=0 [MAV=2.0]

For MAS1_{IND} = 1, the layout of the MAS3 register is shown in Figure 44.

Figure 44. MAS3 register for MAS1_{IND}=1 [MAV=2.0 and Category: E.PT]

The MAS3 fields are described below.

Bit	Description
32:51	Real Page Number (bits 32:51) (RPNL or RPN _{32:51}) [MAV=1.0] The real page number is formed by the upper n bits of (MAS7 _{RPNU} MAS3 _{RPNL}), where n = 64 - log ₂ (page size in bytes) and page size is specified by MAS1 _{TFSIZE} for a tlbwe instruction and by the SIZE field of the TLB entry if a TLB entry is being read by a tlbre or tlbsx instruction. RPN _{0:31} are accessed through MAS7. RPNL bits corresponding to bits that are not implemented in the RPN field of the TLB are treated as reserved.
32:53	Real Page Number (bits 32:53) (RPNL or RPN _{32:53}) [MAV=2.0] The real page number is formed by the upper n bits of (MAS7 _{RPNU} MAS3 _{RPNL}), where n = 64 - log ₂ (page size in bytes) and page size is specified by MAS1 _{TFSIZE} for a tlbwe instruction, by the SIZE field of the TLB entry if a TLB entry is being read by a tlbre or tlbsx instruction or by the LSIZE field of the LRAT entry if an LRAT entry is being read by a tlbre instruction. RPNL bits corresponding to bits that are not implemented in the RPN field of the TLB are treated as reserved.

54:57 **User Bits (U0:U3)**

See the corresponding TLB bit definition in Section 6.7.1. If one or more of these bits is not implemented in the TLB, the corresponding MAS3 bit is treated as reserved.

If MAS1_{IND} = 0, MAS3_{58:63} are defined as follows:58 **User State Execute Enable (UX)**

See the corresponding TLB bit definition in Section 6.7.1.

59 **Supervisor State Execute Enable (SX)**

See the corresponding TLB bit definition in Section 6.7.1.

60 **User State Write Enable (UW)**

See the corresponding TLB bit definition in Section 6.7.1.

61 **Supervisor State Write Enable (SW)**

See the corresponding TLB bit definition in Section 6.7.1.

62 **User State Read Enable (UR)**

See the corresponding TLB bit definition in Section 6.7.1.

63 **Supervisor State Read Enable (SR)**

See the corresponding TLB bit definition in Section 6.7.1.

If MAS1_{IND} = 1, MAS3_{58:63} are defined as follows:58:62 **Sub-Page Size (SPSIZE)**

See the corresponding TLB field definition in Section 6.7.1.

63 **Undefined) (UND)**

The value of this bit is undefined after a *tlbre* or *tlbsx*.

All other fields are reserved.

6.10.3.12 MAS4 Register

The MAS4 register contains fields for specifying default information to be pre-loaded on an Instruction or Data TLB Error interrupt if the Embedded.Hypervisor category is not supported, MAS Register updates are enabled for interrupts directed to the hypervisor (EPCR_{DMIUH} = 0), or the interrupt is directed to the guest state. See Section 6.11.4.7 for more information. MAS4 is a privileged register. The layout of the MAS4 register is shown in Figure 45 for MAV=1.0 and in Figure 46 for MAV=2.0.

Figure 45. MAS4 register [MAV=1.0]

Figure 46. MAS4 register [MAV=2.0]

The MAS4 fields are described below.

Bit Description

- 34:35 **TLBSEL Default Value (TLBSEL)**
Specifies the default value loaded in MAS0_{TLBSEL} on the interrupt.
- 48 **IND Default Value (INDD)**
Specifies the default value loaded in MAS1_{IND} and MAS6_{SIND} on the interrupt.
- 52:55 **Default TSIZE Value (TSIZED) [MAV=1.0]**
Specifies the default value loaded into MAS1_{TSIZE} on a TLB miss exception.
- 52:56 **Default TSIZE Value (TSIZED) [MAV=2.0]**
Specifies the default value loaded into MAS1_{TSIZE} on a TLB miss exception. If MMUCFG_{TWC} = 1, TSIZED is also the default value loaded into MAS6_{ISIZE} on the interrupt.
- 57 **Default ACM Value (ACMD)**
Specifies the default value loaded into MAS2_{ACM} on the interrupt.
- 58 **Default VLE Value (VLED) [Category: VLE]**
Specifies the default value loaded into MAS2_{VLE} on the interrupt.
- 59 **Default W Value (WD)**
Specifies the default value loaded into MAS2_W on the interrupt.
- 60 **Default I Value (ID)**
Specifies the default value loaded into MAS2_I on the interrupt.
- 61 **Default M Value (MD)**
Specifies the default value loaded into MAS2_M on the interrupt.
- 62 **Default G Value (GD)**
Specifies the default value loaded into MAS2_G on the interrupt.
- 63 **Default E Value (ED)**
Specifies the default value loaded into MAS2_E on the interrupt.

All other fields are reserved.

6.10.3.13 MAS5 Register [Category: Embedded.Hypervisor]

The MAS5 register contains fields for specifying LPID and GS values to be used when searching TLB entries with the *tlbsrx*. <E.TWC> and *tlbsx* instructions. The

SLPID and SGS fields are used to match TLPID and TGS fields in the TLB entry. The MAS5 fields are also used for selecting TLB entries to be invalidated by the *tlbilx* <E.HV> or *tlbivax* instructions. MAS5 is a hypervisor resource. The layout of the MAS5 register is shown in Figure 47.

Figure 47. MAS5 register

The MAS5 fields are described below.

Bit	Description
32	Search GS (SGS) Specifies the GS value used when searching the TLB during execution of <i>tlbsrx</i> . <E.TWC> and <i>tlbsx</i> and for selecting TLB entries to be invalidated by <i>tlbilx</i> <E.HV> or <i>tlbivax</i> . The SGS field is compared with the TGS field of each TLB entry to find a matching entry.
52:63	Search Logical Partition ID (SLPID) Specifies the LPID value used when searching the TLB during execution of <i>tlbsrx</i> . <E.TWC> and <i>tlbsx</i> and for selecting TLB entries to be invalidated by <i>tlbilx</i> <E.HV> or <i>tlbivax</i> . The SLPID field is compared with the TLPID field of each TLB entry to find a matching entry. Only the least significant MMUCFG _{LPIDSIZE} bits of SLPID are implemented.

All other fields are reserved.

Programming Note

Hypervisor software should generally treat MAS5 as part of the partition state.

6.10.3.14 MAS6 Register

The MAS6 register contains fields for specifying PID, IND, and AS values to be used when searching TLB entries with the *tlbsx* instruction and, if MMUCFG_{TWC} = 1 or TLBnCFG_{HES} = 1, for specifying the PID, IND, AS, and size of the virtual address space to be used for selecting TLB entries to be invalidated by the *tlbilx* <E.HV> or *tlbivax* instructions. MAS6 is a privileged

register. The layout of the MAS6 register is shown in Figure 48 for MAV=1.0 and in Figure 49 for MAV=2.0.

Figure 48. MAS6 register [MAV = 1.0]

Figure 49. MAS6 register [MAV = 2.0]

The MAS6 fields are described below.

Bit	Description
34:47	Search PID (SPID) Specifies the value of PID used when searching the TLB during execution of <i>tlbsrx</i> . <E.TWC> and <i>tlbsx</i> . It also defines the PID of the TLB entry to be invalidated by <i>tlbilx</i> <E.HV> with T=1 or T=3 and <i>tlbivax</i> with EA ₆₁ =0. The number of bits implemented is the same as the number of bits implemented in the PID register.

Programming Note

The SPID field was referred to as SPID0 in previous versions of the architecture.

52:56	Invalidation Size (ISIZE) [MAV=2.0] ISIZE defines the size of the virtual address space mapped by the TLB entry to be invalidated by <i>tlbilx</i> T=3 <E.HV> and <i>tlbivax</i> . This field is only supported if MMUCFG _{TWC} = 1 or, for any TLB array, TLBnCFG _{HES} = 1. Otherwise this field is reserved.
-------	---

Programming Note

To make code more portable across implementations, software should always set ISIZE before executing *tlbilx* T=3 <E.HV> and *tlbivax*.

62	Indirect Value for Searches (SIND) [MAV=2.0 and Category: Embedded.Page Table] Specifies the value of IND used when searching the TLB during execution of <i>tlbsrx</i> . <E.TWC> and <i>tlbsx</i> . It also defines the Indirect (IND) value of the TLB entry to be invalidated by <i>tlbilx</i> T=3 <E.HV> and <i>tlbivax</i> .
63	Address Space Value for Searches (SAS) Specifies the value of AS used when searching the TLB during execution of <i>tlbsrx</i> . <E.TWC> and <i>tlbsx</i> . It also defines the TS value of the TLB entry to be invalidated by <i>tlbilx</i> T=3 <E.HV> and <i>tlbivax</i> .

All other fields are reserved.

6.10.3.15 MAS7 Register

The MAS7 register contains a field used for reading and writing an LRAT <E.HV.LRAT> or TLB entry. MAS7 register field is also loaded by the execution of the *tlbsx* instruction. The MAS7 register contains the high order address bits of the RPN for a TLB entry in implementations that support more than 32 bits of physical address. If the Embedded.Hypervisor.LRAT category is supported by such implementations, the high-order LRPN bits of the LRAT array can be read into or written from MAS7 by hypervisor software. If the Embedded.Hypervisor.LRAT category is supported, the RPN specified by MAS7 and MAS3 is treated as an LPN for *tlbwe* executed in guest supervisor state (see Section 6.9). If no more than 32 bits of physical addressing are supported, it is implementation-dependent whether MAS7 is implemented. MAS7 is a privileged register. The layout of the MAS7 is shown in Figure 50.

Figure 50. MAS7 register

The MAS7 fields are described below.

Bit	Description
32:63	Real Page Number (bits 0:31) (RPNU or RPN _{0:31}) RPN _{32:53} are accessed through MAS3. RPNU bits corresponding to bits that are not implemented in the RPN field of the TLB are treated as reserved.

6.10.3.16 MAS8 Register [Category: Embedded.Hypervisor]

The MAS8 register contains fields used for reading and writing an LRAT <E.HV.LRAT> or TLB entry. The MAS8 register fields are also loaded from a matching TLB entry by execution of a *tlbsx* instruction that is successful. The associated TLB fields are used to select a TLB entry during TLB address translation and TLB searches, and to force a Data Storage Interrupt to be directed to the hypervisor state. MAS8 is an hypervisor resource. The LPID field of the LRAT is used to select an LRAT entry during LRAT translation. The layout of the MAS8 register is shown in Figure 51.

Figure 51. MAS8 register

The MAS8 fields are described below.

Bit	Description
-----	-------------

- | | |
|-------|---|
| 32 | Translation Guest State (TGS)
See the corresponding TLB bit definition in Section 6.7.1. |
| 33 | Translation Virtualization Fault (VF)
See the corresponding TLB bit definition in Section 6.7.1. |
| 52:63 | Translation Logical Process ID (TLPID)
See the corresponding TLB bit definition in Section 6.7.1 and the LRAT LPID field definition in Section 6.9. |

All other fields are reserved.

Programming Note

Hypervisor software should generally treat MAS8 as part of the partition state. After executing *tlbsx* and *tlbre*, hypervisor software may need to restore MAS8 before returning to guest state. This is especially important if the Embedded.Hypervisor.LRAT category is supported because a guest can execute a *tlbwe* instruction that writes a TLB entry with the MAS8 values.

Programming Note

For a TLB entry with VF=1, hypervisor software should have the execution permission bits set so that an instruction fetch of the page is prevented.

The VF bit can be used to force a Data Storage interrupt for virtualization of MMIO.

6.10.3.17 Accesses to Paired MAS Registers

In 64-bit mode, certain MAS registers can be accessed in pairs with a single *mtspr* or *mfspr* instruction. The registers that can be accessed this way are shown in Table 10. These register pairs are treated as if they are a single 64-bit register by a *mtspr* or *mfspr* instruction.

Table 10: MAS Register Pairs

64-bit Pairs	SPR Number	Privileged <i>mtspr</i> & <i>mfspr</i>	Cat ²
MAS5 MAS6	348	hypv ¹	E.HV; 64
MAS8 MAS1	349	hypv ¹	E.HV; 64
MAS7 MAS3	372	yes	64
MAS0 MAS1	373	yes	64

1 This register is a hypervisor resource, and can be accessed by one of these instructions only in hypervisor state (see Chapter 2).

2 See Section 1.3.5 of Book I. If multiple categories are listed, the register pair is only provided if all categories are supported. Otherwise the SPR number is treated as reserved.

6.10.3.18 MAS Register Update Summary

Table 11 summarizes how MAS registers are modified by Instruction TLB Error interrupt, Data TLB Error interrupt and the *TLB Management* instructions.

Table 11: MAS Register Update Summary for TLB operations

MAS Field Updated	Value Loaded on Event

1. If MSR_{CM}=0 (32-bit mode) at the time of the exception, EPN_{0:31} are set to 0.
2. If the E.HV category is not supported, MAS Register updates are enabled for interrupts directed to the hypervisor (EPCR_{DMIUH} = 0), or the interrupt is directed to the guest state.
3. MAS5 and MAS8 are not updated on a Data or Instruction TLB Error interrupt. The hypervisor should ensure they already contain values appropriate to the partition.

6.11 Storage Control Instructions

6.11.1 Cache Management Instructions

This section describes aspects of cache management that are relevant only to privileged software programmers.

For a *dcbz* or *dcba* instruction that causes the target block to be newly established in the data cache without being fetched from main storage, the hardware need not verify that the associated real address is valid. The existence of a data cache block that is associated with an invalid real address (see Section 6.6) can cause a

delayed Machine Check interrupt or a delayed Check-stop.

Each implementation provides an efficient means by which software can ensure that all blocks that are considered to be modified in the data cache have been copied to main storage before the thread enters any power conserving mode in which data cache contents are not retained.

Data Cache Block Invalidate *X-form*

dcbi RA, RB

	31	///	RA	RB	470	/
0	6		11	16	21	31

```
if RA=0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
InvalidateDataCacheBlock( EA )
```

Let the effective address (EA) be the sum (RA)0+(RB).

If the block containing the byte addressed by EA is in storage that is Memory Coherence Required and a block containing the byte addressed by EA is in the data cache of any thread, then the block is invalidated in those data caches. On some implementations, before the block is invalidated, if any locations in the block are considered to be modified in any such data cache, those locations are written to main storage and additional locations in the block may be written to main storage.

If the block containing the byte addressed by EA is in storage that is not Memory Coherence Required and a block containing the byte addressed by EA is in the data cache of this thread, then the block is invalidated in that data cache. On some implementations, before the block is invalidated, if any locations in the block are considered to be modified in that data cache, those locations are written to main storage and additional locations in the block may be written to main storage.

The function of this instruction is independent of whether the block containing the byte addressed by EA is in storage that is Write Through Required or Caching Inhibited.

This instruction is treated as a *Store* (see Section 6.7.6.5) on implementations that invalidate a block without first writing to main storage all locations in the block that are considered to be modified in the data cache, except that the invalidation is not ordered by

mbar. On other implementations this instruction is treated as a *Load* (see the section cited above).

If a thread holds a reservation and some other thread executes a *dcbi* that specifies a location in the same reservation granule, the reservation may be lost only if the *dcbi* is treated as a *Store*.

dcbi may cause a cache locking exception, the details of which are implementation-dependent.

This instruction is privileged.

Special Registers Altered:

None

6.11.2 Cache Locking [Category: Embedded Cache Locking]

The *Embedded Cache Locking* category defines instructions and methods for locking cache blocks for frequently used instructions and data. Cache locking allows software to instruct the cache to keep latency sensitive data readily available for fast access. This is accomplished by marking individual cache blocks as locked.

A locked block differs from a normal block in the cache in the following way:

- blocks that are locked in the cache do not participate in the normal replacement policy when a block must be replaced.

6.11.2.1 Lock Setting and Clearing

Blocks are locked into the cache by software using *Cache Locking* instructions. The following instructions are provided to lock data items into the data and instruction cache:

- ***dcbtls*** - Data cache block touch and lock set.
- ***dcbtstls*** - Data cache block touch for store and lock set.
- ***icbtls*** - Instruction cache block touch and lock set.

The RA and RB operands in these instructions are used to identify the block to be locked. The CT field indicates which cache in the cache hierarchy should be targeted. (See Section 4.3 of Book II.)

These instructions are similar in nature to the ***dcbt***, ***dcbst***, and ***icbt*** instructions, but are not hints and thus locking instructions do not execute speculatively and may cause additional exceptions. For unified caches, both the instruction lock set and the data lock set target the same cache.

Similarly, blocks are unlocked from the cache by software using *Lock Clear* instructions. The following instructions are provided to unlock instructions and data in their respective caches:

- ***dcblc*** - Data cache block lock clear.
- ***icblc*** - Instruction cache block lock clear.

The RA and RB operands in these instructions are used to identify the block to be unlocked. The CT field indicates which cache in the cache hierarchy should be targeted.

Additionally, an implementation-dependent method can be provided for software to clear all the locks in the cache.

An implementation is not required to unlock blocks that contain data that has been invalidated unless it is explicitly unlocked with a ***dcblc*** or ***icblc*** instruction; if the implementation does not unlock the block upon invalidation, the block remains locked even though it contains invalid data. If the implementation does not clear locks when the associated block is invalidated,

the method of locking is said to be *persistent*; otherwise it is *not persistent*. An implementation may choose to implement locks as persistent or not persistent; however, the preferred method is persistent.

It is implementation-dependent if cache blocks are implicitly unlocked in the following ways:

- A locked block is invalidated as the result of a ***dcbi***, ***dcbf***, ***dcbfep***, ***icbi***, or ***icbiep*** instruction.
- A locked block is evicted because of an overlocking condition.
- A snoop hit on a locked block that requires the block to be invalidated. This can occur because the data the block contains has been modified external to the thread, or another thread has explicitly invalidated the block.
- The entire cache containing the locked block is invalidated.

6.11.2.2 Error Conditions

Setting locks in the cache can fail for a variety of reasons. A *Lock Set* instruction addressing a byte in storage that is not allowed to be accessed by the storage access control mechanism (see Section 6.7.6) will cause a Data Storage interrupt (DSI). Addresses referenced by *Cache Locking* instructions are always translated as data references; therefore, ***icbtls*** instructions that fail to translate or are not allowed by the storage access control mechanism cause Data TLB Error interrupts and Data Storage interrupts, respectively. Additionally, cache locking and clearing operations can fail due to non-privileged access. The methods for determining other failure conditions such as unable-to-lock or overlocking (see below), is implementation-dependent.

If the Embedded.Hypervisor category is supported and $MSR_{P_{UCLEP}} = 1$, an attempt to execute a *Cache Locking* instruction in guest state results in an Embedded Hypervisor Privilege exception if $MSR_{PR} = 0$ or a cache locking exception if $MSR_{PR} = 1$. When the Embedded.Hypervisor category is not supported, $MSR_{P_{UCLEP}} = 0$, or $MSR_{GS} = 0$, then if a *Cache Locking* instruction is executed in user mode and MSR_{UCLE} is 0, a cache locking exception occurs. If a Data Storage interrupt occurs as a result of a cache locking exception, one of the following ESR or GESR bits is set to 1 (GESR if the Embedded.Hypervisor category is supported and the interrupt is directed to the guest. Otherwise, ESR).

Bit	Description
42	<i>DLK₀</i>
0	Default setting.
1	A <i>dcbtls</i> , <i>dcbstls</i> , or <i>dcblc</i> instruction was executed in user mode.

- 43 **DLK₁**
- 0 Default setting.
 - 1 An **icbtl**s or **icblc** instruction was executed in user mode.

[Category:Embedded.Hypervisor]

The behavior of cache locking instructions in guest privileged state (**dcbtls**, **dcbtstls**, **dcblc**, **icbtls**, **icblc**) is dependent on the setting of MSRP_{UCLEP}. When MSRP_{UCLEP} = 0, cache locking instructions are permitted to execute normally in the guest privileged state. When MSRP_{UCLEP} = 1, cache locking instructions are not permitted to execute in the guest privileged state and cause an Embedded Hypervisor Privilege exception when executed. See Section 4.2.2, “Machine State Register Protect Register (MSRP)”.

6.11.2.2.1 Overlocking

If no exceptions occur for the execution of an **dcbtls**, **dcbtstls**, or **icbtls** instruction, an attempt is made to lock the specified block into the cache. If all of the available cache blocks into which the specified block may be loaded are already locked, an overlocking condition occurs. The overlocking condition may be reported in an implementation-dependent manner.

If an overlocking condition occurs, it is implementation-dependent whether the specified block is not locked into the cache or if another locked block is evicted and the specified block is locked.

The selection of which block is replaced in an overlocking situation is implementation-dependent. The overlocking condition is still said to exist, and is reflected in any implementation-dependent overlocking status.

An attempt to lock a block that is already present and valid in the cache will not cause an overlocking condition.

If a cache block is to be loaded because of an instruction other than a *Cache Management* or *Cache Locking* instruction and all available blocks into which the block can be loaded are locked, the instruction executes and completes, but no cache blocks are unlocked and the block is not loaded into the cache.

Programming Note

Since caches may be shared among threads, an overlocking condition may occur when loading a block even though a given thread has not locked all the available cache blocks. Similarly, blocks may be unlocked as a result of invalidations by other threads.

- The target address is marked Caching Inhibited, or the storage control attributes of the address use a coherency protocol that does not support locking.
- The target cache is disabled or not present.
- The CT field of the instructions contains a value not supported by the implementation.
- Any other implementation-specific error conditions are detected.

If an unable-to-lock or unable-to-unlock condition occurs, the lock set or unlock instruction is treated as a no-op and the condition may be reported in an implementation-dependent manner.

6.11.2.2.2 Unable-to-lock and Unable-to-unlock Conditions

If no exceptions occur and no overlocking condition exists, an attempt to set or unlock a lock may fail if any of the following are true:

6.11.2.3 Cache Locking Instructions

Data Cache Block Touch and Lock Set **X-form**

dcbtls CT,RA,RB

0	31	/	CT	RA	RB	166	/	31
	6	7	11	16	21			

Let the effective address (EA) be the sum (RAI0)+(RB).

The **dcbtls** instruction provides a hint that the program will probably soon load from the block containing the byte addressed by EA, and that the block containing the byte addressed by EA is to be loaded and locked into the cache specified by the CT field. (See Section 4.3 of Book II.) If the CT field is set to a value not supported by the implementation, no operation is performed.

If the block already exists in the cache, the block is locked without accessing storage. An unable-to-lock condition may occur (see Section 6.11.2.2.2), or an overlocking condition may occur (see Section 6.11.2.2.1).

The **dcbtls** instruction may complete before the operation it causes has been performed.

The instruction is treated as a *Load*.

This instruction is privileged unless the Embedded Cache Locking.User Mode category is supported. If the Embedded Cache Locking.User Mode category is supported, this instruction is privileged only if MSR_{UCLE}=0.

Special Registers Altered:

None

Instruction Cache Block Touch and Lock Set **X-form**

icbtls CT,RA,RB

0	31	/	CT	RA	RB	486	/	31
	6	7	11	16	21			

Let the effective address (EA) be the sum (RAI0)+(RB).

The **icbtls** instruction causes the block containing the byte addressed by EA to be loaded and locked into the instruction cache specified by CT, and provides a hint that the program will probably soon execute code from the block. See Section 4.3 of Book II for a definition of the CT field.

If the block already exists in the cache, the block is locked without refetching from memory.

Data Cache Block Touch for Store and Lock Set **X-form**

dcbtstls CT,RA,RB

0	31	/	CT	RA	RB	134	/	31
	6	7	11	16	21			

Let the effective address (EA) be the sum (RAI0)+(RB).

The **dcbtstls** instruction provides a hint that the program will probably soon store to the block containing the byte addressed by EA, and that the block containing the byte addressed by EA is to be loaded and locked into the cache specified by the CT field. (See Section 4.3 of Book II.) If the CT field is set to a value not supported by the implementation, no operation is performed.

If the block already exists in the cache, the block is locked without accessing storage. An unable-to-lock condition may occur (see Section 6.11.2.2.2), or an overlocking condition may occur (see Section 6.11.2.2.1).

The **dcbtstls** instruction may complete before the operation it causes has been performed.

The instruction is treated as a *Store*.

This instruction is privileged unless the Embedded Cache Locking.User Mode category is supported. If the Embedded Cache Locking.User Mode category is supported, this instruction is privileged only if MSR_{UCLE}=0.

Special Registers Altered:

None

This instruction treated as a *Load* (see Section 4.3 of Book II).

If an unable-to-lock condition occurs (see Section 6.11.2.2.2) no operation is performed.

This instruction is privileged unless the Embedded Cache Locking.User Mode category is supported. If the Embedded Cache Locking.User Mode category is supported, this instruction is privileged only if MSR_{UCLE}=0.

Special Registers Altered:

None

Instruction Cache Block Lock Clear *X-form*

icblc CT,RA,RB

0	31	/	CT	RA	RB	230	/	31
	6	7	11	16	21			

Let the effective address (EA) be the sum (RAI0)+(RB).

The block containing the byte addressed by EA in the instruction cache specified by the CT field is unlocked.

The instruction is treated as a *Load*.

If an unable-to-lock condition occurs (see Section 6.11.2.2.2) no operation is performed. If the block containing the byte addressed by EA is not locked in the specified cache, no cache operation is performed.

This instruction is privileged unless the Embedded Cache Locking.User Mode category is supported. If the Embedded Cache Locking.User Mode category is supported, this instruction is privileged only if MSR_{UCLE}=0.

Special Registers Altered:

None

Data Cache Block Lock Clear *X-form*

dcblc CT,RA,RB

0	31	/	CT	RA	RB	390	/	31
	6	7	11	16	21			

Let the effective address (EA) be the sum (RAI0)+(RB).

The block containing the byte addressed by EA in the data cache specified by the CT field is unlocked.

The instruction is treated as a *Load*.

If an unable-to-lock condition occurs (see Section 6.11.2.2.2) no operation is performed. If the block containing the byte addressed by EA is not locked in the specified cache, no cache operation is performed.

This instruction is privileged unless the Embedded Cache Locking.User Mode category is supported. If the Embedded Cache Locking.User Mode category is supported, this instruction is privileged only if MSR_{UCLE}=0.

Special Registers Altered:

None

Programming Note

The *dcblc* and *icblc* instructions are used to remove locks previously set by the corresponding lock set instructions.

6.11.3 Synchronize Instruction

The *Synchronize* instruction is described in Section 4.3 of Book II, but only at the level required by an application programmer (*sync* with L=0 or L=1). Also see Section , “Ordering of Implicit Accesses to the Page Table” on page 957.

In conjunction with the *tlbivax* and *tlbsync* instructions, the *sync* instruction provides an ordering function for TLB invalidations and related storage accesses on other threads as described in the *tlbsync* instruction description on page 1010.

6.11.4 LRAT [Category: Embedded.Hypervisor.LRAT] and TLB Management

Unless the Embedded.Page Table category is supported, no format for the Page Tables or the Page Table Entries is implied. Software has significant flexibility in implementing a custom replacement strategy. For example, software may choose to set IPROT=1 for TLB entries that correspond to frequently used storage, so that those entries are never cast out of the TLB and TLB Miss exceptions to those pages never occur. At a minimum, software must maintain a TLB entry or entries for the Instruction and Data TLB Error interrupt handlers.

TLB management is performed in software with some hardware assist. This hardware assist consists of a minimum of:

- Automatic recording of the effective address causing a TLB Error interrupt. For Instruction TLB Error interrupts, the address is saved in the Save/Restore Register 0. For Data TLB Error interrupts, the address is saved in the Data Exception Address Register.
- Automatic updating of the MAS register on the occurrence of a TLB Error interrupt if the Embedded.Hypervisor category is not supported, MAS Register updates are enabled for interrupts directed to the hypervisor ($EPCR_{DMIUH} = 0$), or the interrupt is directed to the guest state.
- Instructions for reading, writing, searching, invalidating, and synchronizing the TLB. If the Embedded.Hypervisor.LRAT category is supported, a subset of these instructions can also be used for reading and writing the LRAT.

Programming Note

If the Embedded.Hypervisor category is supported and if $EPCR_{TLBGS} DTLBGS = 0b00$, the hypervisor can virtualize the physical TLB by keeping a software copy of at least the guest operating system TLB entries with IPROT=1 and avoid keeping the guest Instruction and Data TLB Error interrupt handlers in the physical TLB.

6.11.4.1 Reading TLB or LRAT Entries

TLB entries can be read by executing *tlbre* instructions. If the Embedded.Hypervisor.LRAT category is supported, LRAT entries can be read by also executing *tlbre* instructions. At the time of *tlbre* execution, a TLB array is selected if $MAS0_{ATSEL}=0$ or $MSR_{GS}=1$. The LRAT array is selected if $MAS0_{ATSEL}=1$ and $MSR_{GS}=0$. The LRAT can be read only when in hypervisor state.

If a TLB array is selected, $MAS0_{TLBSEL}$ selects the TLB array to be written. If $TLBnCFG_{HES}=0$, the TLB entry in the selected TLB array is selected by $MAS0_{ESEL}$ and $MAS2_{EPN}$. In this case, $MAS0_{ESEL}$ selects one of the possible entries that can be used for a given $MAS2_{EPN}$. If $TLBnCFG_{HES}=1$, the TLB entry in the selected TLB array is selected by $MAS0_{ESEL}$ and by a hardware generated hash based on $MAS1_{TID}$ T_{SIZE} , and $MAS2_{EPN}$. In this case, $MAS0_{ESEL}$ selects one of the possible entries that can be used for a given $MAS1_{TID}$ T_{SIZE} and $MAS2_{EPN}$.

If an LRAT array is selected, the LRAT entry is selected by $MAS0_{ESEL}$ and $MAS2_{EPN}$. In this case, $MAS0_{ESEL}$ selects one of the possible entries that can be used for a given $MAS2_{EPN}$.

Specifying invalid values for $MAS0_{TLBSEL}$, $MAS0_{ESEL}$, $MAS2_{EPN}$ or, if $TLBnCFG_{HES}=1$, $MAS1_{TID}$ or $MAS1_{T_{SIZE}}$, results in $MAS1_V$ being set to 0 and undefined results in the other MAS register fields that are loaded by the *tlbre* instruction. Which values are invalid is implementation-dependent. For example, even though an implementation has only one TLB array, the implementation could simply ignore $MAS0_{TLBSEL}$, read the selected entry in the TLB array, and load the MAS registers from the TLB entry regardless of the $MAS0_{TLBSEL}$ value.

Programming Note

When reading TLB entries, $MAS2_{EPN}$ or a subset of the bits in $MAS2_{EPN}$ is used to form the index for accessing the TLB array, i.e. $MAS2_{EPN}$ isn't necessarily an effective page number.

6.11.4.2 Writing TLB or LRAT Entries

TLB entries can be written by executing *tlbwe* instructions. If the Embedded.Hypervisor.LRAT category is supported, LRAT entries can also be written by execut-

ing *tlbwe* instructions. At the time of *tlbwe* execution, a TLB array is selected if $MAS0_{ATSEL}=0$ or $MSR_{GS}=1$. The LRAT array is selected if $MAS0_{ATSEL}=1$ and $MSR_{GS}=0$. The LRAT can be written only when in hypervisor state.

If a TLB array is selected, $MAS0_{TLBSEL}$ selects the TLB array to be written. If $TLBnCFG_{HES}=0$, the TLB entry in the selected TLB array is selected by $MAS0_{ESEL}$ and $MAS2_{EPN}$. In this case, $MAS0_{ESEL}$ selects one of the possible entries that can be used for a given $MAS2_{EPN}$. If $TLBnCFG_{HES}=1$ and $MAS0_{HES}=0$, the TLB entry in the selected TLB array is selected by a hardware generated hash based on $MAS1_{TID}$, $TSIZE$, $MAS2_{EPN}$, and $MAS0_{ESEL}$. In this case, $MAS0_{ESEL}$ selects one of the possible entries that can be used for a given $MAS0_{TLBSEL}$, $MAS1_{TID}$, $TSIZE$, and $MAS2_{EPN}$. If $TLBnCFG_{HES}=1$ and $MAS0_{HES}=1$, the TLB entry in the selected TLB array is selected by a hardware replacement algorithm and a hardware generated hash based on $MAS1_{TID}$, $TSIZE$ and $MAS2_{EPN}$.

If an LRAT array is selected, the LRAT entry is selected by $MAS0_{ESEL}$ and $MAS2_{EPN}$. In this case, $MAS0_{ESEL}$ selects one of the possible entries that can be used for a given $MAS2_{EPN}$. LRAT entries can be written only with $MAS0_{HES}=0$.

At the time of *tlbwe* execution, the MAS registers contain the contents to be written to the indexed TLB entry. Upon completion of the *tlbwe* instruction, the contents of the MAS registers corresponding to TLB entry fields will be written to the indexed TLB entry, except that if the Embedded.Hypervisor.LRAT category is supported, guest execution of *TLB Management* instructions is enabled ($EPCR_{DGTMI}=0$), $MSR_{PR}=0$, $MSR_{GS}=1$, and, for the TLB array to be written, $TLBnCFG_{GTWE}=1$, the RPN from the MAS registers is treated like an LPN and translated by the LRAT, and the RPN from the LRAT is written to the TLB entry if the translation is successful. See Section 6.9. If the LRAT translation fails, an LRAT Miss exception occurs.

If the Embedded.Hypervisor.LRAT category is supported and a guest supervisor executes a *tlbwe* instruction with $MAS1_{IPROT}=1$ or for which the entry to be overwritten has $IPROT=1$, an Embedded Hypervisor Privilege exception occurs. However, if $MAS0_{WQ}=0b01$, it is implementation-dependent whether the Embedded Hypervisor Privilege exception occurs.

If the Embedded.Hypervisor.LRAT category is supported and a guest supervisor executes a *tlbwe* instruction with $MAS0_{HES}=0$, it is implementation-dependent whether the Embedded Hypervisor Privilege exception occurs.

If a TLB entry is being written with $MAS0_{HES}=1$, the hardware replacement algorithm picks an entry in the selected array from the set of entries which can be used for translating addresses with the specified TID, TSIZE and EPN. Whenever possible, an entry with

$IPROT$ equal to 0 is selected. However, an Embedded Hypervisor Privilege exception occurs on a *tlbwe* if all the following conditions are met.

- The Embedded.Hypervisor.LRAT category is supported.
- The *tlbwe* is executed in guest supervisor state.
- $IPROT=1$ for all entries which can be used for translating addresses with the specified TID, TSIZE and EPN.
- $MAS0_{WQ}=0b00$

If $MAS0_{WQ}=0b01$, $MAS0_{HES}=1$, and the first three of the above conditions are met, it is implementation-dependent whether an Embedded Hypervisor Privilege exception occurs.

For TLBs with $TLBnCFG_{HES}=1$, the relationship between the TLB entry selected by a *tlbwe* with $MAS0_{HES}=0$ versus the TLB entry selected by a *tlbwe* with $MAS0_{HES}=1$ is implementation-dependent and may depend on the history of TLB use.

If an invalid value is specified for $MAS0_{TLBSEL}$, $MAS0_{ESEL}$ or $MAS2_{EPN}$, either no TLB entry is written by the *tlbwe*, or the *tlbwe* is performed as if some implementation-dependent, valid value were substituted for the invalid value, or an Illegal Instruction exception occurs. If the page size specified by $MAS1_{TSIZE}$ is not supported by the specified array, the *tlbwe* may be performed as if TSIZE were some implementation-dependent value, or an Illegal Instruction exception occurs.

If the Embedded.Hypervisor category is supported but the Embedded.Hypervisor.LRAT category is not supported, the *tlbwe* instruction is hypervisor privileged. Otherwise, this instruction is privileged.

Programming Note

Since a hardware replacement algorithm selects the entry for a *tlbwe* instruction with $MAS0_{HES}=1$, it is typically not possible to write the same entry using a second *tlbwe* instruction with $MAS0_{HES}=1$. Doing so might create multiple entries for the same virtual page. If software needs to change the value of any of the TLB fields, software should generally invalidate the original entry before executing the second *tlbwe* instruction with the new values.

6.11.4.2.1 TLB Write Conditional [Embedded.TLB Write Conditional]

The *tlbsrx*. <E.TWC> instruction and *tlbwe* instruction with $MAS0_{WQ}=0b01$ together permit a convenient way for software to write a TLB entry while ensuring that the entry is not a duplicate entry and is not a stale, invalid value. Without the *TLB Write Conditional* facility, software must hold a software lock during the process of creating a TLB entry in order to prevent other threads from updating a shared TLB or invalidating a TLB entry.

The **tlbsrx**. <E.TWC> instruction has two effects that occur either at the same time or in the following order.

1. A TLB-reservation is established for a virtual address, and, if the Embedded Page Table category is supported, an associated IND value.
2. A search of the selected TLB array is performed.

The TLB-reservation is used by a subsequent **tlbwe** instruction that writes a TLB entry (i.e. $MAS0_{ATSEL} = 0$ or $MSR_{GS} = 1$) with $MAS0_{WQ} = 0b01$. The TLB is only written by this **tlbwe** if the TLB-reservation still exists at the instant the TLB is written. A **tlbwe** that writes the TLB is said to “succeed”. *TLB Write Conditional* cannot be used for the LRAT.

TLB-reservation

A TLB-reservation is set by a **tlbsrx**. <E.TWC> instruction. The TLB-reservation has an associated IND <E.PT> and virtual address consisting of AS, PID, $EA_{0:53}$, LPID <E.HV>, and GS <E.HV>. These values come from $MAS1_{IND}$ <E.PT>, $MAS1_{TS}$, $MAS1_{TID}$, $MAS2_{EPN}$, $MAS8_{TLPID}$ <E.HV>, and $MAS8_{TGS}$ <E.HV>, respectively. There is no specific page size associated with the TLB-reservation. The TLB-reservation applies to any virtual page that contains the virtual address. There is only one TLB-reservation in a thread.

The TLB-reservation is cleared by any of the following.

- The thread holding the TLB-reservation executes another **tlbsrx**. <E.TWC>: This clears the first TLB-reservation and establishes a new one.
- A **tlbivax** is executed by any thread and all the following conditions are met.
 - Either the Embedded.Hypervisor category is not supported or the $MAS5_{SGS}$ and $MAS5_{SLPID}$ values used by the **tlbivax** match the GS and LPID values associated with the TLB-reservation.
 - The $MAS6_{SPID}$ and $MAS6_{SAS}$ values used by the **tlbivax** match the PID and AS values associated with the TLB-reservation.
 - The $EA_{0:n-1}$ values of the **tlbivax** match the $EA_{0:n-1}$ values associated with the TLB-reservation, where $n = 64 - \log_2(\text{page size in bytes})$ and *page size* is specified by the $MAS6_{ISIZE}$.
- The thread holding the TLB-reservation or another thread that shares the TLB with this thread executes a **mtspr** to MMUCSR0 that performs a TLB invalidate all operation and LPIDR contents of the thread executing the **mtspr** matches the LPID value associated with the TLB-reservation.
- If category Embedded.Hypervisor is supported, and a **tlbilx** with $T = 0$ <E.HV> is executed by the thread holding the TLB-reservation or by a thread that shares the TLB with this thread, and the $MAS5_{SLPID}$ value used by the **tlbilx** <E.HV> matches the LPID value associated with the TLB-reservation.
- If category Embedded.Hypervisor is supported, and a **tlbilx** with $T = 1$ <E.HV> is executed by the thread holding the TLB-reservation or by a thread that shares the TLB with this thread, and the $MAS5_{SLPID}$ and $MAS6_{SPID}$ values used by the **tlbilx** <E.HV> match the LPID and PID values associated with the TLB-reservation.
- If category Embedded.Hypervisor is supported, and a **tlbilx** with $T = 3$ <E.HV> is executed by the thread holding the TLB-reservation or by a thread that shares the TLB with this thread, the $MAS5_{SGS}$, $MAS5_{SLPID}$, $MAS6_{SPID}$, and $MAS6_{SAS}$ values used by the **tlbilx** <E.HV> match the GS, LPID, PID, and AS values associated with the TLB-reservation, and $EA_{0:n-1}$ values of the **tlbilx** <E.HV> match the $EA_{0:n-1}$ values associated with the TLB-reservation, where $n = 64 - \log_2(\text{page size in bytes})$ and *page size* is specified by the $MAS6_{ISIZE}$.
- A **tlbwe** instruction is executed by the thread holding the TLB-reservation or by a thread that shares the TLB with this thread, and all the following are true.
 - An interrupt does not occur as a result of the **tlbwe** instruction.
 - The Embedded.Hypervisor category is not supported or the $MAS8_{TLPID}$ value used by the **tlbwe** match the LPID value associated with the TLB-reservation.
 - The Embedded.Hypervisor category is not supported or the $MAS8_{TGS}$ value used by the **tlbwe** match the GS value associated with the TLB-reservation.
 - The $MAS1_{TID}$ value used by the **tlbwe** matches the PID value associated with the TLB-reservation.
 - The Embedded.Page Table category is not supported or the $MAS1_{IND}$ value used by the **tlbwe** matches the IND value associated with the TLB-reservation.
 - The $MAS1_{TS}$ value used by the **tlbwe** matches the AS value associated with the TLB-reservation.
 - Bits 0:(n-1) of $MAS2_{EPN}$ used by the **tlbwe** match the $EA_{0:n-1}$ values associated with the TLB-reservation, where $n = 64 - \log_2(\text{page size in bytes})$ and *page size* is specified by the $MAS1_{TSIZE}$ used by the **tlbwe**.
 - Either of the following conditions are met.
 - The $MAS0_{WQ}$ used by the **tlbwe** instruction is 0b00.
 - The $MAS0_{WQ}$ used by the **tlbwe** instruction is 0b01 and the TLB-reservation for the thread executing the **tlbwe** exists.
- The thread that has the TLB-reservation or another thread that shares the TLB with this thread that, as a result of a Page Table translation, writes a TLB entry and all the following conditions are met.
 - The TS and $EA_{0:n-1}$ values for the new TLB entry match the corresponding values associ-

ated with the TLB-reservation where $n = 64 - \log_2(\text{page size in bytes})$, where *page size* is specified by the SIZE value written to the TLB entry.

- The Embedded.Hypervisor category is not supported or TLPID for the new TLB entry matches the LPID associated with the TLB-reservation.
- The Embedded.Hypervisor category is not supported or TGS for the new TLB entry matches the GS associated with the TLB-reservation.
- The TID for the new TLB entry matches the PID associated with the TLB-reservation.
- The Valid bit for the new TLB entry is 1.
- The IND value associated with the TLB-reservation is 0.

Implementations are allowed to clear a TLB-reservation for conditions other than those specified above. The architecture assures that a TLB-reservation will be cleared when required per the above requirements, but does not guarantee that these are the only conditions for clearing a TLB-reservation. However, the occurrence of an interrupt does not clear a TLB-reservation.

Programming Note

Software running on two threads that share a TLB should not attempt to create two TLB entries that would both translate a specific virtual address and where the TID or LPID values differ, i.e. one of the values is zero and the other is nonzero. The TLB-reservation will not protect against this case, since a TLB-reservation is not cleared by a *tlbwe* unless there is an exact match on the PID and LPID values.

Likewise software should not attempt to create a Page Table entry and a TLB entry where both entries would translate a specific virtual address, where the TLB array written by the Page Table translation is used by the same thread that uses this TLB entry, and where the TID or LPID values of the PTE and TLB entry differ, i.e. one of the values is zero and the other is nonzero. The TLB-reservation will not protect against this case, since a TLB-reservation is not cleared by a TLB write resulting from a Page Table translation unless there is an exact match on the PID and LPID values.

Synchronization of TLB-reservation

The side-effect of a *tlbsrx*. <E.TWC> instruction setting the TLB-reservation can be synchronized by a context synchronizing instruction or event.

Programming Note

A common operation is to ensure that the TLB-reservation has been set by a *tlbsrx*. <E.TWC> instruction before executing a subsequent *Load* instruction of a software page table entry in order to ensure the TLB-reservation detects an invalidation of the entry that was accessed. Beside using a context synchronizing instruction, software can also ensure the TLB-reservation has been set by a *tlbsrx*. <E.TWC> instruction by reading the CR0 field or CR with a *mfocrf* or *mfcrr* instruction after the *tlbsrx*. <E.TWC> and creating a dependency between the data read from CR0 or CR and the address used for the subsequent *Load* instruction.

Serialization of TLB operations

Regardless of which threads initiated the operations, all operations (reads, writes, invalidates, and searches) involving a single TLB are defined to be serialized such that only one operation occurs at a time. This also applies to a TLB that is shared by multiple threads. Even if there is no matching TLB entry on a *tlbivax*, the TLB is still searched to determine there is no matching entry and this search is still referred to as the TLB invalidation.

If two threads share a TLB and both simultaneously execute a *tlbsrx*. <E.TWC> instruction for a virtual address in a virtual page V, and then both threads execute a *TLB Write Conditional* to create a TLB entry for the virtual page V, at most one of these *tlbwe* instructions succeeds.

If, after thread P1 establishes a TLB-reservation for a virtual address in a virtual page V, another thread P2 executes a *tlbivax* that invalidates a TLB entry for the virtual page V and thread P1 does a *TLB Write Conditional* to create a TLB entry for the virtual page V, then one of the following occurs.

- The TLB invalidation occurs before the TLB write. Thus the TLB-reservation is lost and the *TLB Write Conditional* does not succeed.
- The TLB write occurs before the TLB invalidation. Thus the *TLB Write Conditional* succeeds and the resulting TLB entry created by the *tlbwe* is invalidated by the *tlbivax*.

Forward progress

Forward progress in loops that use *tlbsrx*. <E.TWC> and *tlbwe* with $MAS0_{WQ} = 0b01$ is achieved by a cooperative effort among hardware and system software.

The architecture guarantees that when a thread executes a *tlbsrx*. <E.TWC> to set a TLB-reservation for virtual address X and then a *TLB Write Conditional* to write a TLB entry, either

1. the *TLB Write Conditional* succeeds and the TLB entry is written, or

2. the *TLB Write Conditional* fails because the TLB-reservation was reset because some other thread invalidated all TLB entries in the system for the virtual page containing the virtual address X or some other thread wrote a shared TLB entry for the virtual page containing the virtual address X, or
3. the *TLB Write Conditional* fails because the thread's TLB-reservation was lost for some other reason.

In Case 1 forward progress is made in the sense that the thread successfully wrote the TLB entry. In Case 2, the system as a whole makes progress in the sense that either some thread successfully invalidated TLB entries for virtual address X or some thread that shares the TLB wrote a TLB entry for the virtual page containing virtual address X. Case 3 covers TLB-reservation loss required for correct operation of the rest of the system. This includes TLB-reservation loss caused by some other thread invalidating all entries in a shared TLB, as well as TLB-reservation loss caused by system software invalidating all entries for the PID value associated with virtual address X. It may also include implementation-dependent causes of reservation loss.

An implementation may make a forward progress guarantee, defining the conditions under which the system as a whole makes progress. Such a guarantee must specify the possible causes of TLB-reservation loss in Case 3. While the architecture alone cannot provide such a guarantee, the characteristics listed in Cases 1 and 2 are necessary conditions for any forward progress guarantee. An implementation and operating system can build on them to provide such a guarantee.

Programming Note

The architecture does not include a “fairness guarantee”. In competing for a TLB-reservation, two threads can indefinitely lock out a third.

6.11.4.3 Invalidating TLB Entries

TLB entries may be invalidated by three different methods or if the Embedded.Hypervisor category is supported, by four different methods.

- The TLB entry can be invalidated as the result of a *tlbwe* instruction that sets the MAS1_V bit in the entry to 0.
- TLB entries may be invalidated as a result of a *tlbivax* instruction or from an invalidation resulting from a *tlbivax* on another thread.
- TLB entries may be invalidated as a result of an invalidate all operation specified through appropriate settings in the MMUCSR0.
- If the Embedded.Hypervisor category is supported, TLB entries may be invalidated as a result of a *tlbilx* <E.HV> instruction.

See Section 6.11.4.4 for the effects of the above methods on TLB lookaside information.

In systems consisting of a single-threaded processor as well as in systems consisting of multi-threaded processors, invalidations can occur on a wider set of TLB entries than intended. That is, a virtual address presented for invalidation may cause not only the intended TLB targeted for invalidation to be invalidated, but may also invalidate other TLB entries depending on the implementation. This is because parts of the translation mechanism may not be fully specified to the hardware at invalidate time. This is especially true in SMP systems, where the invalidation address must be supplied to all threads in the system, and there may be other limitations imposed by the hardware implementation. This phenomenon is known as generous invalidates. The architecture assures that the intended TLB will be invalidated, but does not guarantee that it will be the only one. A TLB entry invalidated by writing the V bit of the TLB entry to 0 by use of a *tlbwe* instruction is guaranteed to invalidate only the selected TLB entry. Invalidates occurring from *tlbilx* <E.HV> or *tlbivax* instructions or from *tlbivax* instructions on another thread may cause generous invalidates.

The architecture provides a method to protect against generous invalidations. This is important since there are certain virtual memory regions that must be properly mapped to make forward progress. To prevent this, the architecture specifies an IPROT bit for TLB entries. If the IPROT bit is set to 1 in a given TLB entry, that entry is protected from invalidations resulting from *tlbilx* <E.HV> and *tlbivax* instructions, or from invalidate all operations. TLB entries with the IPROT field set may only be invalidated by explicitly writing the TLB entry and specifying a 0 for the V (MAS1_V) field.

To invalidate one or more individual virtual pages from all TLB arrays in all threads without the involvement of software running on other threads, software can execute the following sequence of instructions.

```

one or more tlbivax instructions
mbar or sync
tlbsync
sync

```

Other instructions, excluding *tlbivax*, may be interleaved with the instruction sequence shown above, but the instructions in the sequence must appear in the order shown. On systems consisting of only a single-threaded processor, the *tlbsync* and the preceding *mbar* or *sync* can be omitted.

Programming Note

For the preceding instruction sequence, the *mbar* or first *sync* instruction prevents the reordering of *tlbivax* instructions previously executed by the thread with respect to the subsequent *tlbsync* instruction. The *tlbsync* instruction and the subsequent *sync* instruction together ensure that all storage accesses for which the address was translated using the translations being invalidated will be performed with respect to any thread or mechanism, to the extent required by the associated Memory Coherence Required and Alternate Coherency Mode attributes, before any data accesses caused by instructions following the *sync* instruction are performed with respect to that thread or mechanism.

Programming Note

Implementations are permitted to have a restriction on the number of threads doing a *tlbivax-mbar/sync-tlbsync-sync* sequence. This restriction could be imposed by the system or the hardware.

Programming Note

The most obvious issue with generous invalidations is the code memory region that serves as the exception handler for MMU faults. If this region does not have a valid mapping, an MMU exception cannot be handled because the first address of the exception handler will result in another MMU exception.

Programming Note

Not all TLB arrays in a given implementation will implement the IPROT attribute. It is likely that implementations that are suitable for demand page environments will implement it for only a single array, while not implementing it for other TLB arrays.

Programming Note

Operating systems and hypervisors need to use great care when using protected (IPROT) TLB entries, particularly in SMP systems. A system that contains TLB entries on other threads will require a cross thread interrupt or some other synchronization mechanism to assure that each thread performs the required invalidation by writing its own TLB entries.

Programming Note

For MMU Architecture Version 1.0, to ensure a TLB entry that is not protected by IPROT is invalidated if software does not know which TLB array the entry is in, software should issue a *tlbivax* instruction targeting each TLB in the implementation with the EA to be invalidated.

Programming Note

The preferred method of invalidating entire TLB arrays is invalidation using MMUCSR0.

Programming Note

Invalidations using MMUCSR0 only affect the TLB array on the thread that performs the invalidation. To perform invalidations on all threads in a coherence domain on a multi-threaded processor or on a system containing multiple single-threaded processors, software should use *tlbivax*. If a large number of TLB entries need to be invalidated, using MMUCSR0 or, if the Embedded.Hypervisor category is supported, *tlbilx* <E.HV>, on each thread may be more efficient.

Programming Note

Since a hardware replacement algorithm selects the entry for a *tlbwe* instruction with $MAS0_{HES} = 1$, it is typically not possible to invalidate the entry using a second *tlbwe* instruction with $MAS0_{HES} = 1$ and $MAS1_V = 0$. If software needs to invalidate a single entry that was written with $MAS0_{HES} = 1$, software should generally invalidate the entry using *tlbilx* with $T=3$ <E.HV> or *tlbivax*.

6.11.4.4 TLB Lookaside Information

For performance reasons, most implementations also have implementation-specific lookaside information that is used in address translation. This lookaside information is a cache of recently used TLB entries.

If $TLBnCFG_{HES}=0$, lookaside information for the associated TLB array is kept coherent with the TLB and is invisible to software. Any write to the TLB array that displaces or updates an entry will be reflected in the lookaside information, invalidating the lookaside information corresponding to the previous TLB entry. Any type of invalidation of an entry in TLB will also invalidate the corresponding entry in the lookaside information.

If $TLBnCFG_{HES}=1$, lookaside information for the associated TLB array is not required to be kept coherent with the TLB. Only in the following conditions will the lookaside information be kept coherent with the TLB. The MMUCSR0 TLB invalidate all will invalidate all lookaside information. The *tlbilx* <E.HV> and *tlbivax*

instructions invalidate lookaside information corresponding to TLB entry values that they are specified to invalidate as well as those TLB entry values that would have been invalidated except for their IPROT=1 value.

The same instructions that synchronize invalidations of TLB entries also synchronize invalidation of TLB lookaside information.

Programming Note

If TLBnCFG_{HES}=1 for a TLB array and it is important that the lookaside information corresponding to a TLB entry be invalidated, software should use *tlbilx* <E.HV> or *tlbivax* to invalidate the virtual address.

6.11.4.5 Invalidating LRAT Entries

There is only one mechanism for invalidating LRAT entries. An LRAT entry can be invalidated as the result of a *tlbwe* instruction that overwrites the LRAT entry with a new valid entry or that sets LRAT_V = 0. Only one LRAT entry is invalidated by a single *tlbwe*.

6.11.4.6 Searching TLB Entries

Software may search the MMU by using the *tlbsx* instruction, and, if Category: TLB Write Conditional category is supported, the *tlbsrx*. <E.TWC> instruction. The *tlbsrx*. <E.TWC> and *tlbsx* instructions use IND, PID, and AS values from the MAS registers instead of the PID registers and the MSR, and, if the Embedded.Hypervisor category is supported, these instructions use an LPID and GS value from the MAS registers instead LPIDR and MSR. This allows software to search address spaces that differ from the current address space defined by the PID registers. This is useful for TLB fault handling.

6.11.4.7 TLB Replacement Hardware Assist

The architecture provides mechanisms to assist software in creating and updating TLB entries when certain MMU related exceptions occur. This is called TLB Replacement Hardware Assist. Hardware will update the MAS registers on the occurrence of a Data TLB Error Interrupt or Instruction TLB Error interrupt if the Embedded.Hypervisor category is not supported, MAS Register updates are enabled for interrupts directed to the hypervisor (EPCR_{DMIUH} = 0), or the interrupt is directed to the guest state.

When a Data or Instruction TLB Error interrupt (TLB miss) occurs and if the Embedded.Hypervisor category is not supported, MAS Register updates are enabled for interrupts directed to the hypervisor (EPCR_{DMIUH} = 0), or the interrupt is directed to the guest state, then MAS0, MAS1, and MAS2 are automatically updated using the defaults specified in MAS4 as well as the AS

and EPN values corresponding to the access that caused the exception. MAS6 is updated to set MAS6_{SPID} to the value of PID, MAS6_{SIND} to the value of MAS4_{INDD}, and MAS6_{SAS} to the value of MSR_{DS} or MSR_{IS} depending on the type of access (data or instruction) that caused the error. In addition, if MAS4_{TLBSELD} identifies a TLB array that supports NV (Next Victim), MAS0_{ESEL} is loaded with a value that hardware predicts represents the best TLB entry to victimize to create a new TLB entry and MAS0_{NV} is updated with the TLB entry index of what hardware predicts to be the next victim for the set of entries which can be used for translating addresses with the EPN that caused the exception. Thus MAS0_{ESEL} identifies the current TLB entry to be replaced, and MAS0_{NV} points to the next victim. When software writes the TLB entry, the MAS0_{NV} field is written to the TLB array's set of next victim values. The algorithm used by the hardware to determine which TLB entry should be targeted for replacement is implementation-dependent.

Next Victim support is provided for TLB arrays that are set associative and that have TLBnCFG_{HES}=0. Next Victim support is not provided for TLB arrays that are fully associative.

The automatic update of the MAS registers sets up all the necessary fields for creating a new TLB entry with the exception of RPN, the U0-U3 attribute bits, and the permission bits. With the exception of the upper 32 bits of RPN and the page attributes (should software desire to specify changes from the default attributes), all the remaining fields are located in MAS3, requiring only the single MAS register manipulation by software before writing the TLB entry.

For Instruction Storage interrupt (ISI) and Data Storage interrupt (DSI) related exceptions, the MAS registers are not updated. Software must explicitly search the TLB to find the appropriate entry.

The update of MAS registers through TLB Replacement Hardware Assist is summarized in Table 11 on page 986.

Programming Note

Next Victim support is not provided for a fully associative array because such an array is intended for mostly static mappings of addresses.

6.11.4.8 32-bit and 64-bit Specific MMU Behavior

MMU behavior is largely unaffected by whether the thread is in 32-bit computation mode (MSR_{CM}=0) or 64-bit computation mode (MSR_{CM}=1). The only differences occur in the EPN field of the TLB entry and the EPN field of MAS2. The differences are summarized here.

- Executing a *tlbwe* instruction in 32-bit mode will set bits 0:31 of the TLB EPN field to 0, regardless of the value of bits 0:31 of the EPN field in MAS2.
- For an update to MAS registers via TLB Replacement Hardware Assist (see Section 6.11.4.7), an update to bits 0:53 of the EPN field occurs regardless of the computation mode of the thread at the time of the exception or the interrupt computation mode in which the interrupt is taken. If the instruction causing the exception was executing in 32-bit mode, bits 0:31 of the EPN field in MAS2 will be set to 0.
- Executing a *tlbre* instruction in 32-bit mode will set bits 0:31 of the MAS2 EPN field to an undefined value.

Programming Note

This allows a 32-bit OS to operate seamlessly in 32-bit mode on a 64-bit implementation and a 64-bit OS to easily support 32-bit applications.

6.11.4.9 TLB Management Instructions

The *tlbivax* instruction is used to invalidate TLB entries. Additional instructions are used to read and write, and search TLB entries, and to provide an order-

ing function for the effects of *tlbivax*. If the Embedded.Hypervisor category is supported, the *tlbilx* instruction is used to invalidate TLB entries in the thread executing the *tlbilx*.

TLB Invalidate Virtual Address Indexed X-form

tlbivax RA, RB

0	31	///	RA	RB	786	/
	6		11	16	21	31

```

if RA = 0 then b ← 0
else b ← (RA)
EA ← b + (RB)
for each thread
  if MAV = 1.0 then for TLB array = EA59:60
  if MAV = 2.0 then for each TLB array
    for each TLB entry
      if MMUCFGTWC = 1 or TLBnCFGHES = 1 then
        c ← MAS6ISIZE
      else
        c ← entrySIZE
      if MAV = 1.0 then
        m ← ¬((1 << (2 × c)) - 1)
      else
        m ← ¬((1 << c) - 1)
      if ((EA0:53 & m) = (entryEPN & m)) &
        entryTID = MAS6SPID & entryTS = MAS6SAS &
        (E.PT not supported | entryIND = MAS6SIND) &
        (E.HV not supported |
          (entryTLPID = MAS5SLPID &
            entryTGS = MAS5SGS) |
          ((MAV = 1.0) & (EA61 = 1)))
        then
          if entryIPROT = 0 then entryV ← 0

```

Let the effective address (EA) be the sum (RA|0)+(RB). The EA is interpreted as show below.

EA_{0:53} EA_{0:53}

EA_{54:58} Reserved

EA_{59:60} TLB array selector [MAV = 1.0]

00 TLB0

01 TLB1

10 TLB2

11 TLB3

EA₆₁ TLB invalidate all [MAV = 1.0]

EA_{62:63} Reserved

If EA₆₁=0, all TLB entries on all threads that have all of the following properties are made invalid. The MAS registers listed are those in the thread executing the *tlbivax*.

- The MMU architecture version is 2.0 or the entry is in the TLB array targeted by EA_{59:60}.

- The logical AND of EA_{0:53} and m is equal to the logical AND of the EPN value of the TLB entry and m, where m is based on the following.
 - If MMUCFG_{TWC} = 1 or TLBnCFG_{HES} = 1, c is equal MAS6_{ISIZE}. Otherwise, c is equal to entry_{SIZE}.
 - If MMU Architecture Version 1.0 is supported, m is equal to the logical NOT of ((1 << (2 × c)) - 1). Otherwise, m is equal to the logical NOT of ((1 << c) - 1).
- The TID value of the TLB entry is equal to MAS6_{SPID} and the TS value of the TLB entry is equal to MAS6_{SAS}.
- The implementation does not support the Embedded.Page Table category or the IND value of the TLB entry is equal to MAS6_{SIND}.
- Either of the following is true:
 - The implementation does not support the Embedded.Hypervisor category.
 - The TLPID value of the TLB entry is equal to MAS5_{SLPID} and the TGS value of the TLB entry is equal to MAS5_{SGS}.
- entry_{IPROT} = 0.

In MMU Architecture Version 1.0 if EA₆₁=1, all entries in all threads not protected by the IPROT attribute in the TLB array targeted by EA_{59:60} are made invalid.

If the instruction specifies a TLB array that does not exist, the instruction is treated as if the instruction form is invalid. If the implementation requires the page size to be specified by MAS6_{ISIZE} (MMUCFG_{TWC} = 1 or, for the specified TLB array, TLBnCFG_{HES} = 1) and the page size specified by MAS6_{ISIZE} is not supported by the implementation, the instruction is treated as if the instruction form is invalid.

If the operation isn't a TLB invalidate all and there are multiple entries in a single thread's TLB array(s) that match the complete VPN, then zero or more matching entries with IPROT=0 are invalidated or a Machine Check interrupt occurs. If the Embedded.Hypervisor category is supported, this Machine Check interrupt must be precise.

The operation performed by this instruction is ordered by the *mbar* (or *sync*) instruction with respect to a subsequent *tlbsync* instruction executed by the thread executing the *tlbivax* instruction. The operations caused by *tlbivax* and *tlbsync* are ordered by *mbar* as a set of operations which is independent of the other sets that *mbar* orders.

The effects of the invalidation on this thread are not guaranteed to be visible to the programming model

until the completion of a context synchronizing operation.

Invalidations may occur for other TLB entries in the designated array, but in no case will any TLB entries with the IPROT attribute set be made invalid.

If RA does not equal 0, it is implementation-dependent whether an Illegal Instruction exception occurs.

If the Embedded.Hypervisor category is supported, this instruction is hypervisor privileged. Otherwise, this instruction is privileged.

Special Registers Altered:

None

Programming Note

Care must be taken not to invalidate any TLB entry that contains the mapping for any interrupt vector.

For backward compatibility, implementations may ignore a TLB entry's TS and TID fields when determining whether an entry should be invalidated. Since this and other such generous invalidation can be performed, consideration should be given to protecting a TLB entry that maps an interrupt vector by setting $TLB_{IPROT} = 1$.

Programming Note

The *tlbilx* <E.HV> instruction is the preferred way of performing TLB invalidations for operating systems running as a guest to the hypervisor since the invalidations are partitioned and do not require hypervisor privilege.

Programming Note

The TLB invalidate all function ($EA_{61}=1$) only exists in MMU Architecture Version 1.0 implementations. It should only be used when running existing software is deemed important.

TLB Invalidate Local Indexed**X-form**

tlbilx RA, RB [Category: Embedded.Hypervisor]]

31	///	T	RA	RB	18	/
0	6	9	11	16	21	31

```

if RA = 0 then b ← 0
else b ← (RA)
EA ← b + (RB)
for each TLB array
  for each TLB entry
    if MMUCFGTWC = 1 or TLBnCFGHES = 1 then
      c ← MAS6ISIZE
    else
      c ← entrySIZE
    if MAV = 1.0 then
      m ← ¬((1 << (2 × c)) - 1)
    else
      m ← ¬((1 << c) - 1)
    if (entryIPROT = 0) & (entryTLPID = MAS5SLPID) then
      if T = 0 then entryV ← 0
      if T = 1 & entryTID = MAS6SPID then entryV ← 0
      if T = 3 & entryTGS = MAS5SGS &
        ((EA0:53 & m) = (entryEPN & m)) &
        entryTID = MAS6SPID & entryTS = MAS6SAS &
        (E.PT not supported | entryIND = MAS6SIND)
      then
        entryV ← 0

```

Let the effective address (EA) be the sum (RA) + (RB).

The **tlbilx** instruction invalidates TLB entries in the thread that executes the **tlbilx** instruction. TLB entries which are protected by the IPROT attribute (entry_{IPROT} = 1) are not invalidated.

If T = 0, all TLB entries that have all of the following properties are made invalid on the thread executing the **tlbilx** instruction.

- The TLPID of the entry matches MAS5_{SLPID}.
- The IPROT of entry is 0.

If T = 1, all TLB entries that have all of the following properties are made invalid on the thread executing the **tlbilx** instruction.

- The TLPID of the entry matches MAS5_{SLPID}.
- The TID of the entry matches MAS6_{SPID}.
- The IPROT of entry is 0.

If T = 3, all TLB entries in the thread executing the **tlbilx** instruction that have all of the following properties are made invalid.

- The TLPID value of the TLB entry is equal to MAS5_{SLPID} and the TGS value of the TLB entry is equal to MAS5_{SGS}.
- The logical AND of EA_{0:53} and m is equal to the logical AND of the EPN value of the TLB entry and m, where m is based on the following.
 - If MMUCFG_{TWC} = 1 or TLBnCFG_{HES} = 1, c is equal MAS6_{ISIZE}. Otherwise, c is equal to entry_{SIZE}.

- If MMU Architecture Version 1.0 is supported, m is equal to the logical NOT of ((1 << (2 × c)) - 1). Otherwise, m is equal to the logical NOT of ((1 << c) - 1).
- The TID value of the TLB entry is equal to MAS6_{SPID} and the TS value of the TLB entry is equal to MAS6_{SAS}.
- The implementation does not support the Embedded.Page Table category or the IND value of the TLB entry is equal to MAS6_{SIND}.
- The IPROT of entry is 0.

The effects of the invalidation are not guaranteed to be visible to the programming model until the completion of a context synchronizing operation.

Invalidations may occur for other TLB entries on the thread executing the **tlbilx** instruction, but in no case will any TLB entries with the IPROT attribute set be made invalid.

If T = 2, the instruction form is invalid.

If T = 3 and the implementation requires the page size to be specified by MAS6_{ISIZE} (MMUCFG_{TWC} = 1 or, for any TLB array, TLBnCFG_{HES} = 1) and the page size specified by MAS6_{ISIZE} is not supported by the implementation, the instruction is treated as if the instruction form is invalid.

If T=3 and there are multiple entries in the TLB array(s) that match the complete VPN, then zero or more matching entries with IPROT=0 are invalidated or a Machine Check interrupt occurs. If the Embedded.Hypervisor category is supported, this Machine Check interrupt must be precise.

If RA does not equal 0, it is implementation-dependent whether an Illegal Instruction exception occurs.

If the Embedded.Hypervisor category is supported and guest execution of *TLB Management* instructions is disabled (EPCR_{DGTMI}=1), this instruction is hypervisor privileged. Otherwise, this instruction is privileged.

Special Registers Altered:

None

Extended Mnemonics:

Examples of extended mnemonics for *TLB Invalidate Local*:

Extended:	Equivalent to:
tlbilxlpid	tlbilx 0,0,0
tlbilxpid	tlbilx 1,0,0
tlbilxva RA,RB	tlbilx 3,RA,RB
tlbilxva RB	tlbilx 3,0,RB

Programming Note

tbilx is the preferred way of performing TLB invalidations, especially for operating systems running as a guest to the hypervisor since the invalidations are partitioned and do not require hypervisor privilege.

Programming Note

When dispatching a guest operating system, hypervisor software should always set `MAS5SLPID` to the guest's corresponding LPID value.

Programming Note

Executing a *tbilx* instruction with `T=0` or `T=1` may take many cycles to perform. Software should only issue these operations when an LPID or a PID value is reused or taken out of use.

Let the effective address (EA) be the sum (RAI0)+(RB).

If any TLB array contains a valid entry matching the MAS1_{IND} <E.PT> and virtual address formed by MAS5_{SGS} <E.HV>, MAS5_{SLPID} <E.HV>, MAS1_{TS TID}, and EA, the search is considered successful. A TLB entry matches if all the following conditions are met.

- The valid bit of the TLB entry is 1.
- The logical AND of EA_{0:53} and m is equal to the logical AND of the EPN value of the TLB entry and m, where m is determined as follows:
 - If MMU Architecture Version 1.0 is supported, m is equal to the logical NOT of ((1 << (2 × entry_{SIZE})) - 1). Otherwise, m is equal to the logical NOT of ((1 << entry_{SIZE}) - 1)
- The TID value of the TLB entry is equal to MAS6_{SPID} or is zero.
- The TS value of the TLB entry is equal to MAS6_{SAS}.
- Either the Embedded.Page Table category is not supported or the IND value of the TLB entry is equal to MAS6_{SIND}.
- Either of the following is true:
 - The implementation does not support the Embedded.Hypervisor category.
 - The TGS value of the TLB entry is equal to MAS5_{SGS} and either the TLPID value of the TLB entry is equal to MAS5_{SLPID} or is zero.

If the search is successful, MAS register fields are loaded from the matching TLB entry according to the following.

- MAS0_{ATSEL} is set to 0.
- MAS0_{TLBSEL} is set to the number of the TLB array with the matching entry.
- MAS0_{ESEL} is set to the index of the matching entry.
- If MAS0_{HES} is supported, MAS0_{HES} is set to 0.
- If Next Victim is supported for any TLB array, the following applies.
 - If the TLB array with the matching entry supports Next Victim, MAS0_{NV} is set to the hardware hint for the index of the entry to be replaced. Otherwise, MAS0_{NV} is set to an implementation-dependent undefined value.
- MAS1_V is set to 1.
- MAS1_{TID TS TSIZE} are loaded from the TID, TS, and SIZE fields of the TLB entry.
- If the TLB array supports IPROT, MAS1_{IPROT} is loaded from the IPROT bit of the TLB entry. Otherwise, MAS1_{IPROT} is set to 0.
- MAS2_{EPN W I M G E} are loaded from the EPN, W, I, M, G, and E fields of the TLB entry.
- If the VLE category is supported, MAS2_{VLE} is loaded from the VLE bit of the TLB entry.
- If Alternate Coherency Mode is supported, MAS2_{ACM} is loaded from the ACM bit of the TLB entry.
- MAS3_{RPNL} is loaded from the lower 22-bits of the RPN field of the TLB entry, and, if implemented, MAS7_{RPNU} is loaded from the upper 32-bits of the RPN field of the TLB entry.
- The supported User-Defined storage control bits in MAS3_{U0:U3} are loaded from the respective supported U0:U3 bits of the TLB entry.
- If the Embedded.Page Table category is not supported, MAS3_{UX SX UW SW UR SR} are loaded from the UX, SX, UW, SW, UR, and SR bits of the TLB entry. Otherwise, the following applies.
 - if the TLB array does not support indirect entries, MAS1_{IND} is set to 0 and MAS3_{UX SX UW SW UR SR} are loaded from the UX, SX, UW, SW, UR, and SR bits of the TLB entry. Otherwise, the following applies.
 - MAS1_{IND} is loaded from the IND bit of the TLB entry.
 - If the IND bit of the TLB entry is 1, MAS3_{SPSIZE} is loaded from the SPSIZE field of the TLB entry, and MAS3_{UND} is set to an implementation-dependent undefined value.
 - If the IND bit of the TLB entry is 0, MAS3_{UX SX UW SW UR SR} are loaded from the UX, SX, UW, SW, UR, and SR bits of the TLB entry.
- If the Embedded.Hypervisor category is implemented, MAS8_{TGS VF TLPID} are loaded from the TGS, VF, and TLPID fields of the TLB entry.

If no valid matching translation exists, MAS1_V is set to 0 and the MAS register fields are loaded according to the following in order to facilitate a TLB replacement.

- MAS0_{ATSEL} is set to 0.
- MAS0_{TLBSEL} is loaded from MAS4_{TLBSELD}.
- If Next Victim is not supported for any TLB array, MAS0_{ESEL} is set to an implementation-dependent undefined value. Otherwise, the following applies.
 - If the TLB array specified by MAS4_{TLBSELD} supports Next Victim, MAS0_{ESEL} is set to the hardware hint for the index of the entry to be replaced and MAS0_{NV} is set to the hardware hint for the index of the next entry to be replaced. Otherwise, MAS0_{ESEL} and MAS0_{NV} are set to implementation-dependent undefined values.
- If MAS0_{HES} is supported, MAS0_{HES} is set to the value of TLBnCFG for the TLB array specified by MAS4_{TLBSELD}.
- MAS1_{IPROT} is set to 0.
- MAS1_{TID TS} are loaded from MAS6_{SPID SAS}.
- MAS1_{TSIZE} is loaded from MAS4_{TSIZED}.
- If the Embedded.Page Table category is supported, MAS1_{IND} is set to MAS4_{INDD}.
- MAS2_{EPN} is set to an implementation-dependent undefined value.
- MAS2_{W I M G E} are loaded from MAS4_{WD ID MD GD ED}.
- If the VLE category is supported, MAS2_{VLE} is loaded from MAS4_{VLED}.
- If Alternate Coherency Mode is supported, MAS2_{ACM} is loaded from MAS4_{ACMD}.
- MAS3_{RPNL} and, if implemented, MAS7_{RPNU} are set to 0s.
- The supported User-Defined storage control bits in MAS_{U0:U3} are set to 0s.
- MAS3_{UX SX UW SW UR SR} are set to 0s.

If the Embedded.TLB Write Conditional category is supported, MAS0_{WQ} is set to 0b01.

If a **tlbsx** is successful, it is considered to “hit”. Otherwise, it is considered to “miss”.

If there are multiple matching TLB entries, either one of the matching entries is used or a Machine Check exception occurs. If the Embedded.Hypervisor category is supported, this Machine Check interrupt must be precise.

If RA does not equal zero, it is implementation-dependent whether an Illegal Instruction exception occurs.

If the Embedded.Hypervisor category is supported, this instruction is hypervisor privileged. Otherwise, this instruction is privileged.

Let the effective address (EA) be the sum (RA) + (RB).

If any TLB array contains a valid entry matching the MAS1_IND <E.PT> and virtual address formed by MAS5_SGS <E.HV>, MAS5_SLPID <E.HV>, MAS1_TS TID, and EA, the search is considered successful. A TLB entry matches if all the following conditions are met.

- The valid bit of the TLB entry is 1.
- Either the Embedded.Page Table category is not supported or the IND value of the TLB entry is equal to MAS1_IND.
- The logical AND of EA_{0:53} and m is equal to the logical AND of the EPN value of the TLB entry and m, where m is determined as follows:
 - If MMU Architecture Version 1.0 is supported, m is equal to the logical NOT of ((1 << (2 ×

entry_SIZE)) - 1). Otherwise, m is equal to the logical NOT of ((1 << entry_SIZE) - 1)

- The TID value of the TLB entry is equal to MAS1_TID or is zero.
- The TS value of the TLB entry is equal to MAS1_TS.
- Either of the following is true:
 - The implementation does not support the Embedded.Hypervisor category.
 - The TGS value of the TLB entry is equal to MAS5_SGS and either the TLPID value of the TLB entry is equal to MAS5_SLPID or is zero.

CR Field 0 is set as follows. n is a 1-bit value that indicates whether the search was successful.

CR0_{LT GT EQ SO} = 0b00 || n || 0

This instruction creates a TLB-reservation for use by a *TLB Write* instruction. The virtual address described above is associated with the TLB-reservation, and replaces any address previously associated with the TLB-reservation. (The TLB-reservation is created regardless of whether the search succeeds.)

If there are multiple matching TLB entries, either one of the matching entries is used or a Machine Check exception occurs. If the Embedded.Hypervisor category is supported, this Machine Check interrupt must be precise.

If RA does not equal zero, it is implementation-dependent whether an Illegal Instruction exception occurs.

If the Embedded.Hypervisor category is supported and guest execution of *TLB Management* instructions is disabled (EPCR_{DGTMI}=1), this instruction is hypervisor privileged. Otherwise, this instruction is privileged.

If the Embedded.Hypervisor.LRAT is not supported, MAS0_ATSEL is treated as if it were zero in the following description.

If the Embedded.Hypervisor.LRAT category is not supported or MAS0_ATSEL is 0, then the following applies.

- If Next Victim is supported for any TLB array, the following applies.
 - If the TLB array specified by MAS0_TLBSEL supports Next Victim, MAS0_NV is set to the hardware hint for the index of the entry to be replaced. Otherwise, MAS0_NV is set to an implementation-dependent undefined value.
- A TLB entry is selected in one of the following ways.
 - if TLBnCFG_HES=0 for the TLB array selected by MAS0_TLBSEL, the TLB entry is specified by MAS0_TLBSEL, MAS0_ESEL and MAS2_EPN.
 - if TLBnCFG_HES=1 for the TLB array selected by MAS0_TLBSEL, the TLB entry is specified by MAS0_TLBSEL, MAS0_ESEL and a hardware generated hash based on MAS1_TID, MAS1_TSIZE, and MAS2_EPN.

If the selected TLB entry exists, MAS register fields are loaded according to the following.

- MAS1_V TID TS TSIZE are loaded from the V, TID, TS, and SIZE fields of the TLB entry.
- If the TLB array supports IPROT, MAS1_IPROT is loaded from the IPROT bit of the TLB entry. Otherwise, MAS1_IPROT is set to 0.
- MAS2_EPN W I M G E are loaded from the EPN, W, I, M, G, and E fields of the TLB entry.
- If the VLE category is supported, MAS2_VLE is loaded from the VLE bit of the TLB entry.

- If Alternate Coherency Mode is supported, $MAS2_{ACM}$ is loaded from the ACM bit of the TLB entry.
- $MAS3_{RPNL}$ is loaded from the lower 22-bits of the RPN field of the TLB entry, and, if implemented, $MAS7_{RPNU}$ is loaded from the upper 32-bits of the RPN field of the TLB entry.
- The supported User-Defined storage control bits in $MAS3_{U0:U3}$ are loaded from the respective supported U0:U3 bits of the TLB entry.
- If the Embedded.Page Table category is not supported, $MAS3_{UX SX UW SW UR SR}$ are loaded from the UX, SX, UW, SW, UR, and SR bits of the TLB entry. Otherwise, the following applies.
 - if the TLB array does not support indirect entries, $MAS1_{IND}$ is set to 0 and $MAS3_{UX SX UW SW UR SR}$ are loaded from the UX, SX, UW, SW, UR, and SR bits of the TLB entry. Otherwise, the following applies.
 - $MAS1_{IND}$ is loaded from the IND bit of the TLB entry.
 - If the IND bit of the TLB entry is 1, $MAS3_{SPSIZE}$ is loaded from the SPSIZE field of the TLB entry, and $MAS3_{UND}$ is set to an implementation-dependent undefined value.
 - If the IND bit of the TLB entry is 0, $MAS3_{UX SX UW SW UR SR}$ are loaded from the UX, SX, UW, SW, UR, and SR bits of the TLB entry.
- If the Embedded.Hypervisor category is implemented, $MAS8_{TGS VF TLPID}$ are loaded from the TGS, VF, and TLPID fields of the TLB entry.

If the Embedded.Hypervisor.LRAT category is supported, the LRAT array is specified ($MAS0_{ATSEL} = 1$), then the following applies.

- $MAS0_{NV}$ is set to an implementation-dependent undefined value.
- If the LRAT entry specified by $MAS0_{ESEL}$ and $MAS2_{EPN}$ exists, MAS register fields are loaded from the LRAT entry according to the following.
 - $MAS1_V TSIZE$ are loaded from the V and LSIZE fields of the LRAT entry.
 - $MAS1_{IPROT TID TS}$, $MAS2_{W I M G E}$, $MAS3_{UX SX UW SW UR SR}$, and $MAS8_{TGS VF}$ are set to 0s.
 - If the Embedded.Page Table category is supported, $MAS1_{IND}$ is set to 0.
 - $MAS2_{EPN}$ is loaded from the LPN field of the LRAT entry.
 - If the VLE category is supported, $MAS2_{VLE}$ is set to 0.
 - If Alternate Coherency Mode is supported, $MAS2_{ACM}$ is set to 0.
 - $MAS3_{RPNL}$ is loaded from the lower 22-bits of the LRPN field of the LRAT entry, and, if implemented, $MAS7_{RPNU}$ is loaded from the upper 32-bits of the LRPN field of the LRAT entry.

- The supported User-Defined storage control bits in $MAS3_{U0:U3}$ are set to 0s.
- $MAS8_{TGS VF}$ are set to 0s.
- If the LPID field in the LRAT is supported ($LRATCFG_{LPID} = 1$), $MAS8_{TLPID}$ is loaded from the TLPID field of the LRAT entry.

If $TLBnCFG_{HES} = 1$ and the page size specified by $MAS1_{TSIZE}$ is not supported by the specified array, the *tlbre* may be performed as if TSIZE were some implementation-dependent value or, as described below, as if the entry can not be found, or an Illegal Instruction exception occurs.

It is implementation-dependent whether a TLB or LRAT entry can not be found or whether larger values of the fields that select an entry are simply mapped to existing entries. If the specified TLB or LRAT entry does not exist, $MAS1_V$ is set to 0 and the following MAS register fields are set to implementation-dependent undefined values.

- $MAS1_{IPROT TID TS TSIZE}$, $MAS2_{EPN W I M G E}$, $MAS3_{UX SX UW SW UR SR}$, $MAS3_{RPNL}$, and, if implemented, $MAS7_{RPNU}$
- If the VLE category is supported, $MAS2_{VLE}$
- If Alternate Coherency Mode is supported, $MAS2_{ACM}$
- The supported User-Defined storage control bits in $MAS3_{U0:U3}$
- If the Embedded.Page Table category is supported, $MAS1_{IND}$
- If the Embedded.Hypervisor category is implemented, $MAS8_{TGS VF TLPID}$

If the Embedded.Hypervisor category is supported, this instruction is hypervisor privileged. Otherwise, this instruction is privileged.

Special Registers Altered:

$MAS0$ $MAS1$ $MAS2$ $MAS3$ $MAS7$
 $MAS8$ (if category E.HV is supported)

Programming Note

Hypervisor software should generally prevent guest operating system visibility of the RPN. After executing a *tlbsx* or *tlbre* on behalf of a guest, the hypervisor should replace the RPN fields in the $MAS3$ and $MAS7$ registers with the corresponding values from the appropriate LPN.

TLB Synchronize**X-form**

tlbsync

0	31	///	///	///	566	/
	6	11	16	21	31	

The **tlbsync** instruction provides an ordering function for the effects of all **tlbivax** instructions executed by the thread executing the **tlbsync** instruction, with respect to the memory barrier created by a subsequent **sync** instruction executed by the same thread. Executing a **tlbsync** instruction ensures that all of the following will occur.

- All TLB invalidations caused by **tlbivax** instructions preceding the **tlbsync** instruction will have completed on any other thread before any data accesses caused by instructions following the **sync** instruction are performed with respect to that thread.
- All storage accesses by other threads for which the address was translated using the translations being invalidated will have been performed with respect to the thread executing the **sync** instruction, to the extent required by the associated Memory Coherence Required attributes, before the **sync** instruction's memory barrier is created.

The operation performed by this instruction is ordered by the **mbar** or **sync** instruction with respect to preceding **tlbivax** instructions executed by the thread executing the **tlbsync** instruction. The operations caused by **tlbivax** and **tlbsync** are ordered by **mbar** as a set of operations, which is independent of the other sets that **mbar** orders.

The **tlbsync** instruction may complete before operations caused by **tlbivax** instructions preceding the **tlbsync** instruction have been performed.

If the Embedded.Hypervisor category is supported, this instruction is hypervisor privileged. Otherwise, this instruction is privileged.

```

If the Embedded.TLB Write Conditional category is not supported, MAS0_WQ is treated as if it were 0b00 in the following description.

If the Embedded.Hypervisor.LRAT category is not supported or $MSR_{GS}=1$, $MAS0_{ATSEL}$ is treated as if it were zero in the following description.

If a TLB array is specified ($MAS0_{ATSEL} = 0$) and $TLBnCFG_{HES}=0$ for the TLB array selected by $MAS0_{TLBSEL}$, $MAS0_{HES}$ is treated as 0 in the following description.

If the Embedded.Page Table category is supported, a TLB array is specified ($MAS0_{ATSEL} = 0$), and the specified TLB array does not support indirect entries, $MAS1_{IND}$ must be 0.

If a TLB array is specified ($MAS0_{ATSEL} = 0$) and $MAS0_{WQ}$ is 0b00 or 0b01, the following applies.

- If the Embedded.Hypervisor is not supported, the *tlbwe* instruction is executed in hypervisor state, or $MAS1_V=0$, an RPN is formed by concatenating $MAS7_{RPNU}$ with $MAS3_{RPNL}$ ($RPN = MAS7_{RPNU} \parallel MAS3_{RPNL}$).
- If the Embedded.Hypervisor category is supported, the *tlbwe* instruction is executed in guest state, and $MAS1_V=1$, an LPN is formed by concatenating $MAS7_{RPNU}$ with $MAS3_{RPNL}$ ($LPN = MAS7_{RPNU} \parallel MAS3_{RPNL}$). However, if MAS7 is not implemented, $LPN = {}^{32}0 \parallel MAS3_{RPNL}$. This LPN is translated by the LRAT to obtain the RPN. If there is no LRAT entry that translates this LPN for the LPID specified by LPIDR, an LRAT Miss exception occurs. However, if $MAS0_{WQ}$ is 0b01 and no TLB-reservation exists, it is implementation-dependent whether the LRAT Miss exception occurs.
- If $TLBnCFG_{HES}$ for the TLB array selected by $MAS0_{TLBSEL}$ is 0, the TLB entry is specified by $MAS0_{TLBSEL}$, $MAS0_{ESEL}$, and $MAS2_{EPN}$. If $TLBnCFG_{HES}$ is 1 and $MAS0_{HES}$ is 1, the TLB entry is selected by $MAS0_{TLBSEL}$, a hardware replacement algorithm, and a hardware generated hash based on $MAS1_{TID\ TSIZE}$, and $MAS2_{EPN}$. If $TLBnCFG_{HES}$ is 1 and $MAS0_{HES}$ is 0, the TLB entry is selected by $MAS0_{TLBSEL}$, $MAS0_{ESEL}$ and a hardware generated hash based on $MAS0_{TLBSEL}$, $MAS1_{TID\ TSIZE}$, and $MAS2_{EPN}$.
- The selected TLB entry is written (see the following major bulleted item) if all the following conditions are met.
 - There is no LRAT Miss exception.
 - $MAS0_{WQ}$ is 0b00 or both the following are true.
 - $MAS0_{WQ}$ is 0b01
 - A TLB-reservation exists.
 - $MAS1_{IPROT}$ is 0, the Embedded.Hypervisor category is not supported, or $MSR_{GS} = 0$.
 - The selected TLB entry has $IPROT = 0$, the Embedded.Hypervisor category is not supported, or $MSR_{GS} = 0$.
- Use the first of the following sub-bullets that applies.
 - If $EPCR_{DGTMI}=1$, no TLB entry is written and a Hypervisor Privilege exception occurs.
 - If the selected entry exists, the selected entry has $IPROT=1$, $MAS0_{WQ}=0b00$, and $MSR_{GS}=1$, no TLB entry is written, and a Hypervisor Privilege exception occurs.
 - If $MAS0_{WQ}=0b00$, $MAS1_V=1$, $MAS1_{IPROT}=1$, and $MSR_{GS}=1$, no TLB entry is written, and a Hypervisor Privilege exception occurs.
 - If $MAS0_{WQ}=0b00$, $MAS1_V=0$, $MAS1_{IPROT}=1$, and $MSR_{GS}=1$, no TLB entry is written, and it is implementation-dependent whether a Hypervisor Privilege exception occurs.
 - If the selected entry has $IPROT=1$, $MAS0_{WQ}=0b01$, and $MSR_{GS}=1$, no TLB entry is written, and it is implementation-dependent whether a Hypervisor Privilege exception occurs.
 - If $MAS0_{WQ}=0b01$, $MAS1_{IPROT}=1$, and $MSR_{GS}=1$, no TLB entry is written, and it is implementation-dependent whether a Hypervisor Privilege exception occurs.
 - If $MAS0_{HES}=0$ and $MSR_{GS}=1$, no TLB entry is written, and it is implementation-dependent whether a Hypervisor Privilege exception occurs.

If a TLB entry is to be written per the preceding description, then regardless of whether the selected TLB entry exists, $MAS0_{NV}$ provides a suggestion to hardware of what the hardware hint for replacement should be when the next Data or Instruction TLB Error Interrupt for a virtual address that uses the set of TLB entries containing the entry written by the *tlbwe* instruction.

If the selected TLB entry exists and the TLB entry is to be written per the preceding description, the fields of the TLB entry are loaded from the MAS registers according to the following.

- The V, TID, TS, and SIZE fields of the TLB entry are loaded from $MAS1_V\ TID\ TS\ TSIZE$.
- If the TLB array supports IPROT, the IPROT bit of the TLB entry is loaded from $MAS1_{IPROT}$.
- The EPN, W, I, M, G, and E fields of the TLB entry are loaded from $MAS2_{EPN\ W\ I\ M\ G\ E}$.
- If the VLE category is supported, the VLE bit of the TLB entry is loaded from $MAS2_{VLE}$.
- If Alternate Coherency Mode is supported, the ACM bit of the TLB entry is loaded from $MAS2_{ACM}$.
- The RPN field of the TLB entry is loaded from the RPN described above.
- The supported User-Defined storage control bits (U0:U3) of the TLB entry are loaded from the respective bits in $MAS3_{U0:U3}$.
- If the Embedded.Page Table category is supported and the TLB array supports indirect entries, the following applies.
 - The IND of the TLB entry is loaded from $MAS1_{IND}$.
 - If $MAS1_{IND}$ is 1, the SPSIZE field of the TLB entry is loaded from $MAS3_{SPSIZE}$.

- If $MAS1_{IND}$ is 0, the UX, SX, UW, SW, UR, and SR bits of the TLB entry are loaded from $MAS3_{UX\ SX\ UW\ SW\ UR\ SR}$.
- If the Embedded.Hypervisor category is implemented, the TGS, VF, and TLPID fields of the TLB entry are loaded from $MAS8_{TGS\ VF\ TLPID}$.

If the LRAT array is specified ($MAS0_{ATSEL} = 1$) for a **tlbwe**, $MAS0_{WQ}$ must be 0b00 and $MAS0_{HES}$ must be 0. If the LRAT array is specified ($MAS0_{ATSEL} = 1$), $MAS0_{WQ}$ is 0b00, $MAS0_{HES}$ is 0, and the **tlbwe** instruction is executed in hypervisor state, the following applies.

- An RPN is formed by concatenating $MAS7_{RPNU}$ with $MAS3_{RPNL}$ ($RPN = MAS7_{RPNU} \parallel MAS3_{RPNL}$).
- The contents of the $MAS1_{V\ TSIZE}$, $MAS2_{EPN}$, and the RPN described above are written to the selected LRAT entry $V_{LSIZE\ LPN\ RPN}$.
- If the LPID field in the LRAT is supported ($LRATCFG_{LPID} = 1$), $MAS8_{TLPID}$ is written to the LPID field of the selected entry.

If no exception occurs, and either $MAS0_{WQ}$ is 0b10 or a TLB array was selected by the **tlbwe** ($MAS0_{ATSEL}=0$ or $MSR_{GS}=1$), the TLB-reservation is cleared.

If $MAS0_{WQ}$ is 0b10, no TLB entry is written.

If $MAS0_{WQ}$ is 0b11, the instruction is treated as if the instruction form is invalid.

If the page size specified by $MAS1_{TSIZE}$ is not supported by the specified array, the **tlbwe** may be performed as if $TSIZE$ were some implementation-dependent value, or an Illegal Instruction exception occurs.

If a TLB entry is to be written per the preceding description, $MAS1_{IND}=1$, and values of I,M,G, and E to be written to the TLB entry are inconsistent with storage that is not Caching Inhibited, Memory Coherence Required, not Guarded, and Big-Endian, the **tlbwe** may be performed as described or an Illegal Instruction exception occurs. Also, if a TLB entry is to be written per the preceding description, $MAS1_{IND}=1$, and values of ACM and U0:U3 to be written to the TLB entry are inconsistent with the requirements that an implementation has for storage control attributes for a Page Table, the **tlbwe** may be performed as described or an Illegal Instruction exception occurs.

If an invalid value is specified for $MAS0_{TLBSEL}$, $MAS0_{ESEL}$ or $MAS2_{EPN}$, either no TLB entry is written by the **tlbwe**, or the **tlbwe** is performed as if some implementation-dependent, valid value were substituted for the invalid value, or an Illegal Instruction exception occurs.

A context synchronizing instruction is required after a **tlbwe** instruction to ensure any subsequent instructions that will use the updated TLB or LRAT values execute in the new context.

If $TLBnCFG_{HES}=1$ for the selected TLB array, a TLB write does not necessarily invalidate implementation-specific TLB lookaside information. See Section 6.11.4.4.

This instruction is hypervisor privileged if the Embedded.Hypervisor category is supported and any of the following is true.

- The Embedded.Hypervisor.LRAT category is not supported.
- $MSR_{GS} = 1$ and, for the TLB array selected by $MAS0_{TLBSEL}$, $TLBnCFG_{GTWE} = 0$.
- Guest execution of *TLB Management* instructions is disabled ($EPCR_{DGTMI}=1$).

Otherwise, this instruction is privileged.

Special Registers Altered:

None

Programming Note

Care must be taken not to invalidate any TLB entry that contains the mapping for any interrupt vector.

7.1 Overview

An *interrupt* is the action in which the thread saves its old context (MSR and next instruction address) and begins execution at a pre-determined interrupt-handler address, with a modified MSR. *Exceptions* are the events that will, if enabled, cause the thread to take an interrupt.

Exceptions are generated by signals from internal and external peripherals, instructions, the internal timer. Interrupts are divided into 4 classes, as described in Section 7.4.3, such that only one interrupt of each class is reported, and when it is processed no program state is lost. Since Save/Restore register pairs GSRR0/GSRR1 <E.HV> SRR0/SRR1, CSRR0/CSRR1, DSRR0/DSRR1 [Category: E.ED], and MCSSR0/MCSSR1 are serially reusable resources used by guest

<E.HV>, base, critical, debug [Category: E.ED], Machine Check interrupts, respectively, program state may be lost when an unordered interrupt is taken. (See Section 7.8, “Interrupt Ordering and Masking”.)

7.2 Interrupt Registers

7.2.1 Save/Restore Register 0

Save/Restore Register 0 (SRR0) is a 64-bit register. SRR0 bits are numbered 0 (most-significant bit) to 63 (least-significant bit). The register is used to save machine state on non-critical interrupts, and to restore machine state when an *rfi* is executed. On a non-critical interrupt, SRR0 is set to the current or next instruc-

tion address. When *rfi* is executed, instruction execution continues at the address in SRR0.

In general, SRR0 contains the address of the instruction that caused the non-critical interrupt, or the address of the instruction to return to after a non-critical interrupt is serviced.

The contents of SRR0 when an interrupt is taken are mode dependent, reflecting the computation mode when the interrupt is taken and the computation mode entered for execution of the interrupt (specified by $EPCR_{ICM} <E.HV>$). When computation mode when the interrupt is taken is 32-bit mode and the computation mode entered for execution of the interrupt is 64-bit mode, the high-order 32 bits of SRR0 are set to 0s. When computation mode when the interrupt is taken is 64-bit mode and the computation mode entered for execution of the interrupt is 32-bit mode, the contents SRR0 are undefined.

The contents of SRR0 upon interrupt can be described as follows (assuming Addr is the address to be put into SRR0):

```
if (MSRCM = 0) & (EPCRICM = 0)
  then SRR0 ← 32undefined || Addr32:63
if (MSRCM = 0) & (EPCRICM = 1)
  then SRR0 ← 320 || Addr32:63
if (MSRCM = 1) & (EPCRICM = 1) then SRR0 ← Addr0:63
if (MSRCM = 1) & (EPCRICM = 0) then SRR0 ← undefined
```

The contents of SRR0 can be read into register RT using *mfspir RT,SRR0*. The contents of register RS can be written into the SRR0 using *mtspir SRR0,RS*.

This register is hypervisor privileged.

7.2.2 Save/Restore Register 1

Save/Restore Register 1 (SRR1) is a 32-bit register. SRR1 bits are numbered 32 (most-significant bit) to 63 (least-significant bit). The register is used to save machine state on non-critical interrupts, and to restore machine state when an *rfi* is executed. When a non-critical interrupt is taken, the contents of the MSR are placed into SRR1. When *rfi* is executed, the contents of SRR1 are placed into the MSR.

Bits of SRR1 that correspond to reserved bits in the MSR are also reserved.

Programming Note

A MSR bit that is reserved may be inadvertently modified by *rfi/rfci/rfmci*.

The contents of SRR1 can be read into register RT using *mfspir RT,SRR1*. The contents of register RS can be written into the SRR1 using *mtspir SRR1,RS*.

This register is hypervisor privileged.

7.2.3 Guest Save/Restore Register 0 [Category:Embedded.Hypervisor]

Guest Save/Restore Register 0 (GSRR0) is a 64-bit register. GSRR0 bits are numbered 0 (most-significant bit) to 63 (least-significant bit). The register is used to save machine state on guest interrupts, and to restore machine state when an *rfgi* is executed. On a guest interrupt, GSRR0 is set to the current or next instruction address. When *rfgi* is executed, instruction execution continues at the address in GSRR0.

In general, GSRR0 contains the address of the instruction that caused the guest interrupt, or the address of the instruction to return to after a guest interrupt is serviced.

The contents of GSRR0 when an interrupt is taken are mode dependent, reflecting the computation mode currently in use (specified by MSR_{CM}) and the computation mode entered for execution of the interrupt (specified by $EPCR_{GICM}$). The contents of GSRR0 upon interrupt can be described as follows (assuming Addr is the address to be put into GSRR0):

```
if (MSRCM = 0) & (EPCRGICM = 0)
  then GSRR0 ← 32undefined || Addr32:63
if (MSRCM = 0) & (EPCRGICM = 1)
  then GSRR0 ← 320 || Addr32:63
if (MSRCM = 1) & (EPCRGICM = 1) then GSRR0 ← Addr0:63
if (MSRCM=1) & (EPCRGICM=0) then GSRR0 ← undefined
```

The contents of GSRR0 can be read into register RT using *mfspir RT,GSRR0*. The contents of register RS can be written into the GSRR0 using *mtspir GSRR0,RS*.

This register is privileged.

Programming Note

mfspir RT,GSRR0 should be used to read GSRR0 in guest supervisor state. *mtspir GSRR0,RS* should be used to write GSRR0 in guest supervisor state. See Section 2.2.1, "Register Mapping".

7.2.4 Guest Save/Restore Register 1 [Category:Embedded.Hypervisor]

Guest Save/Restore Register 1 (GSRR1) is a 32-bit register. GSRR1 bits are numbered 32 (most-significant bit) to 63 (least-significant bit). The register is used to save machine state on guest interrupts, and to restore machine state when an *rfgi* is executed. When a guest interrupt is taken, the contents of the MSR are placed into GSRR1. When *rfgi* is executed, the contents of GSRR1 are placed into the MSR.

Bits of GSRR1 that correspond to reserved bits in the MSR are also reserved.

Programming Note

A MSR bit that is reserved may be inadvertently modified by *rfi/rfgi/rfci/rfdi/rfmc*.

The contents of GSRR1 can be read into register RT using *mf spr RT,GSRR1*. The contents of register RS can be written into the GSRR1 using *mt spr GSRR1,RS*.

This register is privileged.

Programming Note

mf spr RT,SRR1 should be used to read GSRR1 in guest supervisor state. *mt spr SRR1,RS* should be used to write GSRR1 in guest supervisor state. See Section 2.2.1, “Register Mapping”.

7.2.5 Critical Save/Restore Register 0

Critical Save/Restore Register 0 (CSRR0) is a 64-bit register. CSRR0 bits are numbered 0 (most-significant bit) to 63 (least-significant bit). The register is used to save machine state on critical interrupts, and to restore machine state when an *rfci* is executed. When a critical interrupt is taken, the CSRR0 is set to the current or next instruction address. When *rfci* is executed, instruction execution continues at the address in CSRR0.

In general, CSRR0 contains the address of the instruction that caused the critical interrupt, or the address of the instruction to return to after a critical interrupt is serviced.

The contents of CSRR0 when an interrupt is taken are mode dependent, reflecting the computation mode when the interrupt is taken and the computation mode entered for execution of the interrupt (specified by $EPCR_{ICM}$) [Category:Embedded.Hypervisor]. If computation mode when the interrupt is taken is 32-bit mode and the computation mode entered for execution of the interrupt is 64-bit mode, the high-order 32 bits of CSRR0 are set to 0s. When computation mode when the interrupt is taken is 64-bit mode and the computation mode entered for execution of the interrupt is 32-bit mode, the contents CSRR0 are undefined.

The contents of CSRR0 upon critical interrupt can be described as follows (assuming Addr is the address to be put into CSRR0):

```
if (MSRCM = 0) & (EPCRICM = 0)
  then CSRR0 ← 32undefined || Addr32:63
if (MSRCM = 0) & (EPCRICM = 1)
  then CSRR0 ← 320 || Addr32:63
if (MSRCM = 1) & (EPCRICM = 1) then CSRR0 ← Addr0:63
if (MSRCM = 1) & (EPCRICM = 0) then CSRR0 ← undefined
```

The contents of CSRR0 can be read into register RT using *mf spr RT,CSRR0*. The contents of register RS can be written into CSRR0 using *mt spr CSRR0,RS*.

This register is hypervisor privileged.

7.2.6 Critical Save/Restore Register 1

Critical Save/Restore Register 1 (CSRR1) is a 32-bit register. CSRR1 bits are numbered 32 (most-significant bit) to 63 (least-significant bit). The register is used to save machine state on critical interrupts, and to restore machine state when an *rfci* is executed. When a critical interrupt is taken, the contents of the MSR are placed into CSRR1. When *rfci* is executed, the contents of CSRR1 are placed into the MSR.

Bits of CSRR1 that correspond to reserved bits in the MSR are also reserved.

Programming Note

A MSR bit that is reserved may be inadvertently modified by *rfi/rfci/rfmc*.

The contents of CSRR1 can be read into bits 32:63 of register RT using *mf spr RT,CSRR1*, setting bits 0:31 of RT to zero. The contents of bits 32:63 of register RS can be written into the CSRR1 using *mt spr CSRR1,RS*.

This register is hypervisor privileged.

7.2.7 Debug Save/Restore Register 0 [Category: Embedded.Enhanced Debug]

Debug Save/Restore Register 0 (DSRR0) is a 64-bit register used to save machine state on Debug interrupts, and to restore machine state when an *rfdi* is executed. When a Debug interrupt is taken, the DSRR0 is set to the current or next instruction address. When *rfdi* is executed, instruction execution continues at the address in DSRR0.

In general, DSRR0 contains the address of an instruction that was executing or just finished execution when the Debug exception occurred.

The contents of DSRR0 when an interrupt is taken are mode dependent, reflecting the computation mode when the interrupt is taken and the computation mode entered for execution of the interrupt (specified by $EPCR_{ICM}$) [Category:Embedded.Hypervisor]. If computation mode when the interrupt is taken is 32-bit mode and the computation mode entered for execution of the interrupt is 64-bit mode, the high-order 32 bits of DSRR0 are set to 0s. When computation mode when the interrupt is taken is 64-bit mode and the computa-

tion mode entered for execution of the interrupt is 32-bit mode, the contents DSRR0 are undefined.

The contents of DSRR0 upon Debug interrupt can be described as follows (assuming Addr is the address to be put into DSRR0):

```
if (MSRCM = 0) & (EPCRICM = 0) then DSRR0 ← 32undefined || Addr32:63
if (MSRCM = 0) & (EPCRICM = 1) then DSRR0 ← 320 || Addr32:63
if (MSRCM = 1) & (EPCRICM = 1) then DSRR0 ← Addr0:63
if (MSRCM = 1) & (EPCRICM = 0) then DSRR0 ← undefined
```

The contents of DSRR0 can be read into register RT using *mtspr* RT,DSRR0. The contents of register RS can be written into DSRR0 using *mtspr* DSRR0,RS.

This register is hypervisor privileged.

7.2.8 Debug Save/Restore Register 1 [Category: Embedded.Enhanced Debug]

Debug Save/Restore Register 1 (DSRR1) is a 32-bit register used to save machine state on Debug interrupts, and to restore machine state when an *rfdi* is executed. When a Debug interrupt is taken, the contents of the Machine State Register are placed into DSRR1. When *rfdi* is executed, the contents of DSRR1 are placed into the Machine State Register.

Bits of DSRR1 that correspond to reserved bits in the Machine State Register are also reserved.

The contents of DSRR1 can be read into bits 32:63 of register RT using *mtspr* RT,DSRR1, setting bits 0:31 of RT to zero. The contents of bits 32:63 of register RS can be written into the DSRR1 using *mtspr* DSRR1,RS.

This register is hypervisor privileged.

7.2.9 Data Exception Address Register

The Data Exception Address Register (DEAR) is a 64-bit register. DEAR bits are numbered 0 (most-significant bit) to 63 (least-significant bit). The DEAR contains the address that was referenced by a *Load*, *Store* or *Cache Management* instruction that caused an LRAT Error interrupt <E.PT> or that caused an Alignment, Data TLB Miss, Data Storage interrupt if either the Embedded.Hypervisor category is not supported or the interrupt is directed to the hypervisor.

The contents of the DEAR when an interrupt is taken are mode dependent, reflecting the computation mode currently in use (specified by MSR_{CM}) and the computation mode entered for execution of the critical interrupt (specified by EPCR_{ICM}). The contents of the DEAR upon interrupt can be described as follows (assuming Addr is the address to be put into DEAR):

```
if (MSRCM = 0) & (EPCRICM = 0)
then DEAR ← 32undefined || Addr32:63
if (MSRCM = 0) & (EPCRICM = 1)
then DEAR ← 320 || Addr32:63
if (MSRCM = 1) & (EPCRICM = 1) then DEAR ← Addr0:63
if (MSRCM = 1) & (EPCRICM = 0) then DEAR ← undefined
```

The contents of DEAR can be read into register RT using *mtspr* RT,DEAR. The contents of register RS can be written into the DEAR using *mtspr* DEAR,RS.

This register is hypervisor privileged.

7.2.10 Guest Data Exception Address Register [Category: Embedded.Hypervisor]

The Guest Data Exception Address Register (GDEAR) is a 64-bit register. GDEAR bits are numbered 0 (most-significant bit) to 63 (least-significant bit). The GDEAR contains the address that was referenced by a *Load*, *Store* or *Cache Management* instruction that caused an Alignment, Data TLB Miss, or Data Storage interrupt that was directed to the guest supervisor state. The GDEAR is identical in form and function to DEAR.

The contents of the GDEAR when an interrupt is taken are mode dependent, reflecting the computation mode currently in use (specified by MSR_{CM}) and the computation mode entered for execution of the interrupt (specified by EPCR_{GICM}). The contents of the GDEAR upon interrupt can be described as follows (assuming Addr is the address to be put into GDEAR):

```
if (MSRCM = 0) & (EPCRGICM = 0)
then GDEAR ← 32undefined || Addr32:63
if (MSRCM = 0) & (EPCRGICM = 1)
then GDEAR ← 320 || Addr32:63
if (MSRCM = 1) & (EPCRGICM = 1)
then GDEAR ← Addr0:63
if (MSRCM = 1) & (EPCRGICM = 0)
then GDEAR ← undefined
```

The contents of GDEAR can be read into register RT using *mtspr* RT,GDEAR. The contents of register RS can be written into the GDEAR using *mtspr* GDEAR,RS.

This register is privileged.

Programming Note

mtspr RT,DEAR should be used to read GDEAR in guest supervisor state. *mtspr* DEAR,RS should be used to write GDEAR in guest supervisor state. See Section 2.2.1, "Register Mapping".

7.2.11 Interrupt Vector Prefix Register

The Interrupt Vector Prefix Register (IVPR) is a 64-bit register. Interrupt Vector Prefix Register bits are numbered 0 (most-significant bit) to 63 (least-significant bit).

The IVPR is used for Machine Check interrupt if the MCIVPR is not supported. The IVPR is used for other interrupts if Category E.HV is not supported or if the interrupt is directed to the hypervisor state. For these interrupts, the IVPR is used in one of the following ways.

- If Interrupt Vector Offset Registers [Category: Embedded.Phased-Out] are supported, the following applies. Bits 48:63 are reserved. Bits 0:47 of the Interrupt Vector Prefix Register provide the high-order 48 bits of the address of the exception processing routines. The 16-bit exception vector offsets from the appropriate IVOR (provided in Section 7.2.15) are concatenated to the right of bits 0:47 of the Interrupt Vector Prefix Register to form the 64-bit address of the exception processing routine.
- If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, the following applies. IVPR_{52:63} are reserved. Bits 0:51 of the Interrupt Vector Prefix Register provide the high-order 52 bits of the address of the exception processing routines. The 12-bit exception vector offsets (provided in Section 7.2.15) are concatenated to the right of bits 0:47 of the Interrupt Vector Prefix Register to form the 64-bit address of the exception processing routine.

The contents of Interrupt Vector Prefix Register can be read into register RT using *mfspr RT,IVPR*. The contents of register RS can be written into Interrupt Vector Prefix Register using *mtspr IVPR,RS*.

This register is hypervisor privileged.

7.2.12 Guest Interrupt Vector Prefix Register [Category: Embedded.Hypervisor.Phased-Out]

The Guest Interrupt Vector Prefix Register (GIVPR) is a 64-bit register. Interrupt Vector Prefix Register bits are numbered 0 (most-significant bit) to 63 (least-significant bit).

If Interrupt Vector Offset Registers [Category: Embedded.Phased-Out] are supported, the following applies. GIVPR_{48:63} are reserved. For interrupts directed to guest state, bits 0:47 of the Guest Interrupt Vector Prefix Register provides the high-order 48 bits of the address of the exception processing routines. The 16-bit exception vector offsets (provided in Section 7.2.15) are concatenated to the right of bits 0:47 of the Guest

Interrupt Vector Prefix Register to form the 64-bit address of the exception processing routine.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, the following applies. GIVPR_{52:63} are reserved. For interrupts directed to guest state, bits 0:51 of the Guest Interrupt Vector Prefix Register provide the high-order 52 bits of the address of the exception processing routines. The 12-bit exception vector offsets (provided in Section 7.2.15) are concatenated to the right of bits 0:47 of the Guest Interrupt Vector Prefix Register to form the 64-bit address of the exception processing routine.

The contents of Guest Interrupt Vector Prefix Register can be read into register RT using *mfspr RT,GIVPR*. The contents of register RS can be written into Interrupt Vector Prefix Register using *mtspr GIVPR,RS*.

Write access to this register is hypervisor privileged. Read access to this register is privileged.

Programming Note

mfspr RT,IVPR should be used to read GIVPR in guest supervisor state. *mtspr IVPR,RS* should be used to write GIVPR in guest supervisor state. Hypervisor software should emulate the accesses for the guest.

7.2.13 Exception Syndrome Register

The Exception Syndrome Register (ESR) is a 32-bit register. ESR bits are numbered 32 (most-significant bit) to 63 (least-significant bit). The ESR provides a *syndrome* to differentiate between the different kinds of exceptions that can generate the same interrupt type. Upon the generation of one of these types of interrupts,

the bit or bits corresponding to the specific exception that generated the interrupt is set, and all other ESR bits are cleared. Other interrupt types do not affect the contents of the ESR. The ESR does not need to be cleared by software. Figure 52 shows the bit definitions for the ESR.

Bit(s)	Name	Meaning	Associated Interrupt Type
32:35		Implementation-dependent	(Implementation-dependent)
36	PIL	Illegal Instruction exception	Program
37	PPR	Privileged Instruction exception	Program
38	PTR	Trap exception	Program
39	FP	Floating-point operation	Alignment Data Storage Data TLB Program
40	ST	Store operation	Alignment Data Storage Data TLB Error
41		Reserved	
42	DLK ₀	(Implementation-dependent)	(Implementation-dependent)
43	DLK ₁	(implementation-dependent)	(Implementation-dependent)
44	AP	Auxiliary Processor operation	Alignment Data Storage Data TLB Program
45	PUO	Unimplemented Operation exception	Program
46	BO	Byte Ordering exception	Data Storage Instruction Storage
47	PIE	Imprecise exception	Program
48:52		Reserved	
53	DATA	Data Access [Category: Embedded.Page Table]	LRAT Error
54	TLBI	TLB Ineligible [Category: Embedded.Page Table]	Data Storage Instruction Storage
55	PT	Page Table [Category: Embedded.Page Table]	Data Storage Instruction Storage LRAT Error
56	SPV	Signal Processing operation [Category: Signal Processing Engine] Vector operation [Category: Vector]	Alignment Data Storage Data TLB Embedded Floating-point Data Embedded Floating-point Round SPE/Embedded Floating-point/Vector Unavailable
57	EPID	External Process ID operation [Category: Embedded.External Process ID]	Alignment Data Storage Data TLB
58	VLEMI	VLE operation [Category: VLE]	Alignment Data Storage Data TLB SPE/Embedded Floating-point/Vector Unavailable Embedded Floating-point Data Embedded Floating-point Round Instruction Storage Program System Call

Bit(s)	Name	Meaning	Associated Interrupt Type
59:61		Implementation-dependent	(Implementation-dependent)
62	MIF	Misaligned Instruction [Category: VLE]	Instruction TLB Instruction Storage

Figure 52. Exception Syndrome Register Definitions

Programming Note

The information provided by the ESR is not complete. System software may also need to identify the type of instruction that caused the interrupt, examine the TLB entry accessed by a data or instruction storage access, as well as examine the ESR to fully determine what exception or exceptions caused the interrupt. For example, a Data Storage interrupt may be caused by both a Protection Violation exception as well as a Byte Ordering exception. System software would have to look beyond ESR_{BO} , such as the state of MSR_{PR} in $SRR1$ and the page protection bits in the TLB entry accessed by the storage access, to determine whether or not a Protection Violation also occurred.

The contents of the ESR can be read into bits 32:63 of register RT using *mfspir RT,ESR*, setting bits 0:31 of RT to zero. The contents of bits 32:63 of register RS can be written into the ESR using *mtspir ESR,RS*.

This register is hypervisor privileged.

7.2.14 Guest Exception Syndrome Register [Category: Embedded.Hypervisor]

The Guest Exception Syndrome Register (GESR) is a 32-bit register. GESR bits are numbered 32 (most-significant bit) to 63 (least-significant bit). The GESR is identical in form and function to the ESR, but is updated in place of the ESR when an interrupt is directed to the guest. For a description of bit settings and meanings see Section 7.2.13, “Exception Syndrome Register”.

The contents of the GESR can be read into bits 32:63 of register RT using *mfspir RT,GESR*, setting bits 0:31 of RT to zero. The contents of bits 32:63 of register RS can be written into the GESR using *mtspir GESR,RS*.

This register is privileged.

Programming Note

mfspir RT,ESR should be used to read GESR in guest supervisor state. *mtspir ESR,RS* should be used to write GESR in guest supervisor state. See Section 2.2.1, “Register Mapping”

7.2.15 Interrupt Vector Offset Registers [Category: Embedded.Phased-Out]

The Interrupt Vector Prefix Register (IVPR) is a 64-bit register. Interrupt Vector Prefix Register bits are numbered 0 (most-significant bit) to 63 (least-significant bit).

The IVPR is used for Machine Check interrupt if the $MCIVPR$ is not supported. The IVPR is used for other interrupts if Category E.HV is not supported or if the interrupt is directed to the hypervisor state. For these interrupts, the IVPR is used in one of the following ways.

- If Interrupt Vector Offset Registers [Category: Embedded.Phased-Out] are supported, the following applies. Bits 48:63 are reserved. Bits 0:47 of the Interrupt Vector Prefix Register provide the high-order 48 bits of the address of the exception processing routines. The 16-bit exception vector offsets from the appropriate IVOR (provided in Section 7.2.15) are concatenated to the right of bits 0:47 of the Interrupt Vector Prefix Register to form the 64-bit address of the exception processing routine.
- If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, the following applies. $IVPR_{52:63}$ are reserved. Bits 0:51 of the Interrupt Vector Prefix Register provide the high-order 52 bits of the address of the exception processing routines. The 12-bit exception vector offsets (provided in Section 7.2.15) are concatenated to the right of bits 0:47 of the Interrupt Vector Prefix Register to form the 64-bit address of the exception processing routine.

IVOR _i	Interrupt
IVOR0	Critical Input

IVOR 42	LRAT Error Interrupt
IVOR43 : IVOR63	Implementation-dependent

Figure 53. Interrupt Vector Offset Register

Assignments

Bits 48:59 of the contents of IVOR_i can be read into bits 48:59 of register RT using *mtspr RT,IVOR_i*, setting bits 0:47 and bits 60:63 of GPR(RT) to zero. Bits 48:59 of the contents of register RS can be written into bits 48:59 of IVOR_i using *mtspr IVOR_i,RS*.

These registers are hypervisor privileged.

7.2.16 Guest Interrupt Vector Offset Register [Category: Embedded.Hypervisor.Phased-Out]

The Guest Interrupt Vector Offset Registers (GIVORs) are 32-bit registers. Guest Interrupt Vector Offset Register bits are numbered 32 (most-significant bit) to 63 (least-significant bit). Bits 32:47 and bits 60:63 are reserved. A Guest Interrupt Vector Offset Register provides the quadword index from the base address provided by the GIVPR (see Section 7.2.12) for its respective guest state interrupt. Guest Interrupt Vector Offset Registers are analogous to Interrupt Vector Offset Registers except that they are used when an interrupt is directed to the guest supervisor state. Figure 54 provides the assignments of specific Guest Interrupt Vector Offset Registers to specific interrupts.

IVOR _i	Interrupt
GIVOR2	Data Storage
GIVOR3	Instruction Storage
GIVOR4	External Input
GIVOR8	System Call
GIVOR13	Data TLB Error
[Category: Embedded.Hypervisor.LRAT]	
IVOR 42	LRAT Error Interrupt
IVOR43 : IVOR63	Implementation-dependent

Figure 54. Guest Interrupt Vector Offset Register Assignments

Bits 48:59 of the contents of GIVOR_i can be read into bits 48:59 of register RT using *mtspr RT,GIVOR_i*, setting bits 0:47 and bits 60:63 of GPR(RT) to zero. Bits 48:59 of the contents of register RS can be written into bits 48:59 of GIVOR_i using *mtspr GIVOR_i,RS*.

Write access to these registers is hypervisor privileged. Read access to these registers is privileged.

Programming Note

mfspir RT,IVORi should be used to read GIVORi in guest supervisor state. *mtspir IVORi,RS* should be used to write GIVOR in guest supervisor state. Hypervisor software should emulate the accesses for the guest.

Programming Note

The architecture only provides a few GIVORs that are implemented in hardware that are performance critical. Hypervisor software should emulate access to IVORs that do not have corresponding GIVORs.

7.2.17 Logical Page Exception Register [Category: Embedded.Hypervisor and Embedded.Page Table]

The Logical Page Exception Register (LPER) is a 64-bit register that is required when both the Embedded.Hypervisor and Embedded.Page Table categories are supported. LPER bits are numbered 0 (most-significant bit) to 63 (least-significant bit).

Figure 55. Logical Page Exception Register

The LPER fields are described below.

Bit	Definition
12:52	Abbreviated Logical Page Number (ALPN) This field contains the Abbreviated Real Page Number from the PTE which caused the LRAT Error interrupt. Only bits corresponding to the PTE _{ARPN} bits supported by the implementation need be implemented.
60:63	Logical Page Size (LPS) This field contains the Page Size from the PTE that caused the LRAT Error interrupt.

All other fields are reserved.

The LPER contains the values of the ARPN and PS fields from the PTE that was used to translate a virtual address for an instruction fetch, *Load*, *Store* or *Cache Management* instruction that caused an LRAT Error interrupt as a result of an LRAT Miss exception. The contents of LPER are unchanged by an interrupt for any other type of exception.

The LPER is a hypervisor resource.

The contents of the Logical Page Exception Register can be read into register RT using *mfspir RT,LPER*. On a 32-bit implementation, the contents of LPER_{0:31} can be read into register RT_{32:63} using *mfspir RT,LPERU*.

The contents of register RS can be written into the LPER using *mtspir LPER,RS*. On a 32-bit implementation, the contents of register RS_{32:63} can be written into the LPER_{0:31} using *mtspir LPERU,RS*.

On a 32-bit implementation that supports fewer than 33 bits of real address, it is implementation-dependent whether the SPR number for LPERU is treated as a reserved value for *mfspir* and *mtspir*.

The LPER is a hypervisor resource.

7.2.18 Machine Check Registers

A set of Special Purpose Registers are provided to support Machine Check interrupts.

7.2.18.1 Machine Check Save/Restore Register 0

Machine Check Save/Restore Register 0 (MCSRR0) is a 64-bit register used to save machine state on Machine Check interrupts, and to restore machine state when an *rfmci* is executed. When a Machine Check interrupt is taken, the MCSRR0 is set to the current or next instruction address. When *rfmci* is executed, instruction execution continues at the address in MCSRR0.

In general, MCSRR0 contains the address of an instruction that was executing or about to be executed when the Machine Check exception occurred.

The contents of MCSRR0 when a Machine Check interrupt is taken are mode dependent, reflecting the computation mode currently in use (specified by MSR_{CM}) and the computation mode entered for execution of the Machine Check interrupt (specified by EPCR_{ICM}) [Category:Embedded.Hypervisor]. The contents of MCSRR0 upon Machine Check interrupt can be described as follows (assuming Addr is the address to be put into MCSRR0):

```

if (MSRCM = 0) & (EPCRICM = 0)
  then MCSRR0 ← 32undefined || Addr32:63
if (MSRCM = 0) & (EPCRICM = 1)
  then MCSRR0 ← 320 || Addr32:63
if (MSRCM = 1) & (EPCRICM = 1) then MCSRR0 ← Addr0:63
if (MSRCM=1) & (EPCRICM=0) then MCSRR0 ← undefined

```

The contents of MCSRR0 can be read into register RT using *mfspir RT,MCSRR0*. The contents of register RS can be written into MCSRR0 using *mtspir MCSRR0,RS*.

This register is hypervisor privileged.

7.2.18.2 Machine Check Save/Restore Register 1

Machine Check Save/Restore Register 1 (MCSRR1) is a 32-bit register used to save machine state on Machine Check interrupts, and to restore machine state

when an *rfmci* is executed. When a Machine Check interrupt is taken, the contents of the MSR are placed into MCSRR1. When *rfmci* is executed, the contents of MCSRR1 are placed into the MSR.

Bits of MCSRR1 that correspond to reserved bits in the MSR are also reserved.

Programming Note

A MSR bit that is reserved may be inadvertently modified by *rfi/rfci/rfmc*.

The contents of MCSRR1 can be read into register RT using *mfspr RT,MCSRR1*. The contents of register RS can be written into the MCSRR1 using *mtspr MCSRR1,RS*.

This register is hypervisor privileged.

7.2.18.3 Machine Check Syndrome Register

MCSR (MCSR) is a 64-bit register that is used to record the cause of the Machine Check interrupt. The specific definition of the contents of this register are implementation-dependent (see the User Manual of the implementation).

The contents of MCSR can be read into register RT using *mfspr RT,MCSR*. The contents of register RS can be written into the MCSR using *mtspr MCSR,RS*.

This register is hypervisor privileged.

7.2.18.4 Machine Check Interrupt Vector Prefix Register

The Machine Check Interrupt Vector Prefix Register (MCIVPR) is a 64-bit register. MCIVPR is supported only if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported. Whether the MCIVPR is supported is implementation-dependent.

Machine Check Interrupt Vector Prefix Register bits are numbered 0 (most-significant bit) to 63 (least-significant bit). MCIVPR_{52:63} are reserved. Bits 0:51 of the Machine Check Interrupt Vector Prefix Register provide the high-order 52 bits of the address of the Machine Check exception processing routine. The 12-bit Machine Check exception vector offset (provided in Section 7.2.15) is concatenated to the right of bits 0:47 of the Machine Check Interrupt Vector Prefix Register to form the 64-bit address of the Machine Check exception processing routine.

The contents of Machine Check Interrupt Vector Prefix Register can be read into register RT using *mfspr RT,IVPR*. The contents of register RS can be written into Machine Check Interrupt Vector Prefix Register using *mtspr IVPR,RS*.

Programming Note

In some implementations that support Interrupt Fixed Offsets, certain instruction cache errors result in a Machine Check exception. The Machine Check interrupt handler needs to be in Caching Inhibited storage in order for the interrupt handler to operate despite an instruction cache error.

7.2.19 External Proxy Register [Category: External Proxy]

The External Proxy Register (EPR) contains implementation-dependent information related to an External Input interrupt when an External Input interrupt occurs. The EPR is only considered valid from the time that the External Input Interrupt occurs until MSR_{EE} is set to 1 as the result of a *mtmsr* or a return from interrupt instruction.

The format of the EPR is shown below.

Figure 56. External Proxy Register

When the External Input interrupt is taken, the contents of the EPR provide information related to the External Input Interrupt.

This register is hypervisor privileged.

Programming Note

The EPR is provided for faster interrupt processing as well as situations where an interrupt must be taken, but software must delay the resultant processing for later.

The EPR contains the vector from the interrupt controller. The process of receiving the interrupt into the EPR acknowledges the interrupt to the interrupt controller. The method for enabling or disabling the acknowledgment of the interrupt by placing the interrupt-related information in the EPR is implementation-dependent. If this acknowledgment is disabled, then the EPR is set to 0 when the External Input interrupt occurs.

7.2.20 Guest External Proxy Register [Category: Embedded Hypervisor, External Proxy]

The Guest External Proxy Register (GEPR) contains implementation-dependent information related to an External Input interrupt when an External Input interrupt directed to the guest occurs. The GEPR is only considered valid from the time that the External Input Interrupt

occurs until MSR_{EE} is set to 1 as the result of a *mtmsr* or a return from interrupt instruction.

The format of the GEPR is shown below.

Figure 57. Guest External Proxy Register

When the External Input interrupt is taken in the guest supervisor state, the contents of the GEPR provide information related to the External Input Interrupt.

The contents of the GEPR can be read into bits 32:63 of register RT using *mfspr RT,GEPR*, setting bits 0:31 of RT to zero. The contents of bits 32:63 of register RS can be written into the GEPR using *mtspr GEPR,RS*.

The GEPR is identical in form and function to the EPR.

This register is privileged.

Programming Note

The GEPR is provided for faster interrupt processing as well as situations where an interrupt must be taken, but software must delay the resultant processing for later.

The GEPR contains the vector from the interrupt controller. The process of receiving the interrupt into the GEPR acknowledges the interrupt to the interrupt controller. The method for enabling or disabling the acknowledgment of the interrupt by placing the interrupt-related information in the GEPR is implementation-dependent. If this acknowledgment is disabled, then the GEPR is set to 0 when the External Input interrupt occurs.

Programming Note

mfspr RT,EPR should be used to read GEPR in guest supervisor state. Hypervisor software should emulate the accesses for the guest. This keeps the programming model consistent for an operating system running as a guest and running directly in hypervisor state.

Programming Note

Writing the GEPR register is allowed from both guest supervisor state and hypervisor state. Hypervisor must be able to write GEPR to virtualize External Input interrupt handling for the guest if the guest is using External Proxy. Writing to EPR from the guest is not mapped and results in the same behavior as any undefined supervisor level SPR.

7.3 Exceptions

There are two kinds of exceptions, those caused directly by the execution of an instruction and those caused by an asynchronous event. In either case, the exception may cause one of several types of interrupts to be invoked.

Examples of exceptions that can be caused directly by the execution of an instruction include but are not limited to the following:

- an attempt to execute a reserved-illegal instruction (Illegal Instruction exception type Program interrupt)
- an attempt by an application program to execute a 'privileged' instruction (Privileged Instruction exception type Program interrupt)
- an attempt by an application program to access a 'privileged' Special Purpose Register (Privileged Instruction exception type Program interrupt)
- an attempt by an application program to access a Special Purpose Register that does not exist (Unimplemented Operation Instruction exception type Program interrupt)
- an attempt by a system program to access a Special Purpose Register that does not exist (boundedly undefined results)
- the execution of a defined instruction using an invalid form (Illegal Instruction exception type Program interrupt, Unimplemented Operation exception type Program interrupt, or Privileged Instruction exception type Program interrupt)
- an attempt to access a storage location that is either unavailable (Instruction TLB Error interrupt or Data TLB Error interrupt) or not permitted (Instruction Storage interrupt or Data Storage interrupt)
- an attempt to access storage with an effective address alignment not supported by the implementation (Alignment interrupt)
- the execution of a *System Call* instruction (System Call interrupt)
- the execution of a *Trap* instruction whose trap condition is met (Trap type Program interrupt)
- the execution of a floating-point instruction when floating-point instructions are unavailable (Floating-point Unavailable interrupt)
- the execution of a floating-point instruction that causes a floating-point enabled exception to exist (Enabled exception type Program interrupt)
- the execution of a defined instruction that is not implemented by the implementation (Illegal Instruction exception or Unimplemented Operation exception type of Program interrupt)
- the execution of an instruction that is not implemented by the implementation (Illegal Instruction exception or Unimplemented Operation exception type of Program interrupt)
- the execution of an auxiliary processor instruction when the auxiliary processor instruction is unavailable (Auxiliary Processor Unavailable interrupt)
- the execution of an instruction that causes an auxiliary processor enabled exception (Enabled exception type Program interrupt)

The invocation of an interrupt is precise, except that if one of the imprecise modes for invoking the Floating-point Enabled Exception type Program interrupt is in effect then the invocation of the Floating-point Enabled Exception type Program interrupt may be imprecise. When the interrupt is invoked imprecisely, the excepting instruction does not appear to complete before the next instruction starts (because one of the effects of the excepting instruction, namely the invocation of the interrupt, has not yet occurred).

7.4 Interrupt Classification

All interrupts, except for Machine Check, can be classified as either Asynchronous or Synchronous. Independent from this classification, all interrupts, including Machine Check, can be classified into one of the following classes:

- Guest [Category:Embedded.Hypervisor]
- Base
- Critical
- Machine Check
- Debug[Category:Embedded.Enhanced Debug].

7.4.1 Asynchronous Interrupts

Asynchronous interrupts are caused by events that are independent of instruction execution. For asynchronous interrupts, the address reported to the exception handling routine is the address of the instruction that would have executed next, had the asynchronous interrupt not occurred.

7.4.2 Synchronous Interrupts

Synchronous interrupts are those that are caused directly by the execution (or attempted execution) of instructions, and are further divided into two classes, *precise* and *imprecise*.

Synchronous, precise interrupts are those that *precisely* indicate the address of the instruction causing the exception that generated the interrupt; or, for certain synchronous, precise interrupt types, the address of the immediately following instruction.

Synchronous, imprecise interrupts are those that may indicate the address of the instruction causing the

exception that generated the interrupt, or some instruction after the instruction causing the exception.

7.4.2.1 Synchronous, Precise Interrupts

When the execution or attempted execution of an instruction causes a synchronous, precise interrupt, the following conditions exist at the interrupt point.

- GSRR0 [Category: Embedded.Hypervisor], SRR0, CSRR0, or DSRR0 [Category: Embedded.Enhanced Debug] addresses either the instruction causing the exception or the instruction immediately following the instruction causing the exception. Which instruction is addressed can be determined from the interrupt type and status bits.
- An interrupt is generated such that all instructions preceding the instruction causing the exception appear to have completed with respect to the executing thread. However, some storage accesses associated with these preceding instructions may not have been performed with respect to other threads and mechanisms.
- The instruction causing the exception may appear not to have begun execution (except for causing the exception), may have been partially executed, or may have completed, depending on the interrupt type. See Section 7.7 on page 1054.
- Architecturally, no subsequent instruction has executed beyond the instruction causing the exception.

7.4.2.2 Synchronous, Imprecise Interrupts

When the execution or attempted execution of an instruction causes an imprecise interrupt, the following conditions exist at the interrupt point.

When the execution or attempted execution of an instruction causes an imprecise interrupt, the following conditions exist at the interrupt point.

- GSRR0 [Category: Embedded.Hypervisor], SRR0, or CSRR0 addresses either the instruction causing the exception or some instruction following the instruction causing the exception that generated the interrupt.
- An interrupt is generated such that all instructions preceding the instruction addressed by GSRR0 [Category: Embedded.Hypervisor], SRR0, or CSRR0 appear to have completed with respect to the executing thread.
- If the imprecise interrupt is forced by the context synchronizing mechanism, due to an instruction that causes another exception that generates an interrupt (e.g., Alignment, Data Storage), then GSRR0 [Category: Embedded.Hypervisor] or SRR0 addresses the interrupt-forcing instruction, and the interrupt-forcing instruction may have

been partially executed (see Section 7.7 on page 1054).

- If the imprecise interrupt is forced by the execution synchronizing mechanism, due to executing an execution synchronizing instruction other than **sync** or **isync**, then GSRR0 [Category: Embedded.Hypervisor], SRR0, or CSRR0 addresses the interrupt-forcing instruction, and the interrupt-forcing instruction appears not to have begun execution (except for its forcing the imprecise interrupt). If the imprecise interrupt is forced by an **sync** or **isync** instruction, then GSRR0 [Category: Embedded.Hypervisor], SRR0, or CSRR0 may address either the **sync** or **isync** instruction, or the following instruction.
- If the imprecise interrupt is not forced by either the context synchronizing mechanism or the execution synchronizing mechanism, then the instruction addressed by GSRR0 [Category: Embedded.Hypervisor], SRR0, or CSRR0 may have been partially executed (see Section 7.7 on page 1054).
- No instruction following the instruction addressed by GSRR0 [Category: Embedded.Hypervisor], SRR0, or CSRR0 has executed.

7.4.3 Interrupt Classes

Interrupts can also be classified as guest [Category: Embedded.Hypervisor], base, critical, Machine Check, and Debug [Category: Embedded.Enhanced Debug].

Interrupt classes other than the guest [Category: Embedded.Hypervisor] or base class may demand immediate attention even if another class of interrupt is currently being processed and software has not yet had the opportunity to save the state of the machine (i.e. return address and captured state of the MSR). For this reason, the interrupts are organized into a hierarchy (see Section 7.8). To enable taking a critical, Machine Check, or Debug [Category: Embedded.Enhanced Debug] interrupt immediately after a guest [Category: Embedded.Hypervisor] or base class interrupt occurs (i.e. before software has saved the state of the machine), these interrupts use the Save/Restore Register pair CSRR0/CSRR1, MCSRR0/MCSRR1, or DSRR0/DSRR1 [Category: Embedded.Enhanced Debug], and guest [Category: Embedded.Hypervisor] and base class interrupts use Save/Restore Register pairs GSRR0/GSRR1 and SRR0/SRR1 respectively.

Interrupts use Save/Restore Register pair SRR0/SRR1.

7.4.4 Machine Check Interrupts

Machine Check interrupts are a special case. They are typically caused by some kind of hardware or storage subsystem failure, or by an attempt to access an invalid address. A Machine Check may be caused indirectly by the execution of an instruction, but not be recognized and/or reported until long after the thread has executed

past the instruction that caused the Machine Check. As such, Machine Check interrupts cannot properly be thought of as synchronous or asynchronous, nor as precise or imprecise. The following general rules apply to Machine Check interrupts:

1. No instruction after the one whose address is reported to the Machine Check interrupt handler in MCSRR0 has begun execution.
2. The instruction whose address is reported to the Machine Check interrupt handler in MCSRR0, and all prior instructions, may or may not have completed successfully. All those instructions that are ever going to complete appear to have done so already, and have done so within the context existing prior to the Machine Check interrupt. No further interrupt (other than possible additional Machine Check interrupts) will occur as a result of those instructions.

7.5 Interrupt Processing

Associated with each kind of interrupt is an *interrupt vector*, that is the address of the initial instruction that is executed when the corresponding interrupt occurs.

When category Embedded.Hypervisor is implemented, interrupts are directed (see Section 2.3.1, “Directed Interrupts”) to the guest supervisor state or the hypervisor state, which effects how some MSR bits are set. The conditions under which a given interrupt is directed to the guest supervisor state or hypervisor state is more fully described in the interrupt definitions for each interrupt in Section 7.6, “Interrupt Definitions”.

Interrupt processing consists of saving a small part of the thread’s state in certain registers, identifying the cause of the interrupt in another register, and continuing execution at the corresponding interrupt vector location. When an exception exists that will cause an interrupt to be generated and it has been determined that the interrupt can be taken, the following actions are performed, in order:

1. GSRR0 [Category: Embedded.Hypervisor], SRR0, DSRR0 [Category: Embedded.Enhanced Debug], MCSRR0, or CSRR0 is loaded with an instruction address that depends on the interrupt; see the specific interrupt description for details.
2. The GESR [Category: Embedded.Hypervisor] or ESR is loaded with information specific to the exception. Note that many interrupts can only be caused by a single kind of exception event, and thus do not need nor use an ESR setting to indicate to the cause of the interrupt was.
3. GSRR1 [Category: Embedded.Hypervisor], SRR1, DSRR1 [Category: Embedded.Enhanced Debug], or MCSRR1, or CSRR1 is loaded with a copy of the contents of the MSR.

4. The MSR is updated as described below. The new values take effect beginning with the first instruction following the interrupt. MSR bits of particular interest are the following.

- MSR_{EE,PR,FP,FE0,FE1,IS,DS,SPV} are set to 0 by all interrupts.
- If Category E.HV is supported, MSR_{WE} and MSR_{GS} are left unchanged when an interrupt is directed to the guest supervisor state, otherwise they are set to 0 by all interrupts.
- If Category E.HV is supported, MSR_{PMM} is left unchanged when an interrupt is directed to the guest supervisor state and MSR_{PMM} = 1, otherwise MSR_{PMM} is set to 0 by all interrupts.
- If Category E.HV is supported, MSR_{UCLE} is left unchanged when an interrupt is directed to the guest supervisor state and MSR_{UCLEP} = 1, otherwise MSR_{UCLE} is set to 0 by all interrupts.
- MSR_{ME} is set to 0 by Machine Check interrupts and left unchanged by all other interrupts.
- MSR_{CE} is set to 0 by critical class interrupts, Debug interrupts, and Machine Check interrupts, and is left unchanged by all other interrupts.
- MSR_{DE} is set to 0 by critical class interrupts unless Category E.ED is supported, by Debug interrupts, and by Machine Check interrupts, and is left unchanged by all other interrupts.
- If Category E.HV is supported and the interrupt is directed to the guest supervisor state, MSR_{CM} is set to EPCR_{GICM}, otherwise MSR_{CM} is set to EPCR_{ICM}.
- Other supported MSR bits are left unchanged by all interrupts.

See Section 4.2.1 for more detail on the definition of the MSR.

5. Instruction fetching and execution resumes, using the new MSR value, at a location specific to the interrupt. If Category E.HV is supported, and the interrupt is directed to the guest state, the location is one of the following, where IVORi (GIVORi) is the (Guest) Interrupt Vector Offset Register for that interrupt (see Figure 54 on page 1021):

- GIVPR_{0:47} || GIVORi_{48:59} || 0b0000 if Interrupt Vector Offset Registers [Category: Embedded.Phased-Out] are supported
- GIVPR_{0:51} || fixed offset shown in Figure Figure 53 on page 1021 if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported

Otherwise, the location is one of the following:

- IVPR_{0:47} || IVORi_{48:59} || 0b0000 if Interrupt Vector Offset Registers [Category: Embedded.Phased-Out] are supported

- $IVPR_{0:51}$ || fixed offset shown in Figure Figure 53 on page 1021 if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported and either MCIVPR is not supported or the interrupt is not a Machine Check
- $MCIVPR_{0:51}$ || fixed offset shown in Figure Figure 53 on page 1021 if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, MCIVPR is supported, and the interrupt is a Machine Check

The contents of the (Guest) Interrupt Vector Prefix Register, Machine Check Interrupt Vector Prefix Register, and (Guest) Interrupt Vector Offset Registers are indeterminate upon power-on reset, and must be initialized by system software using the *mtspr* instruction.

It is implementation-dependent whether interrupts clear reservations obtained with *lbarx*, *lharx*, *lwarx*, or *ldarx*.

Interrupts might not clear reservations obtained with *Load and Reserve* instructions. The operating system or hypervisor should do so at appropriate points, such as at process switch or a partition switch.

At the end of an interrupt handling routine, execution of an *rfgi* [Category: Embedded.Hypervisor], *rfi*, *rfdi* [Category: Embedded.Enhanced Debug], *rfmci*, or *rfci* causes the MSR to be restored from the contents of GSRR1 [Category: Embedded.Hypervisor], SRR1, DSRR1 [Category: Embedded.Enhanced Debug], MCSRR1, or CSRR1, and instruction execution to resume at the address contained in GSRR0 [Category: Embedded.Hypervisor], SRR0, DSRR0 [Category: Embedded.Enhanced Debug], MCSRR0, or CSRR0, respectively.

Programming Note

In general, at process switch (partition switch), due to possible process interlocks and possible data availability requirements, the operating system (hypervisor) needs to consider executing the following.

- *stbcx.*, *sthcx.*, *stwcx.* or *stdcx.*, to clear the reservation if one is outstanding, to ensure that a *lbarx*, *lharx*, *lwarx* or *ldarx* in the “old” process (partition) is not paired with a *stbcx.*, *sthcx.*, *stwcx.*, or *stdcx.* in the “new” process (partition).
- *sync*, to ensure that all storage operations of an interrupted process are complete with respect to other threads before that process begins executing on another thread.
- *isync*, *rfgi* <E.HV>, *rfi*, *rfdi* [Category: Embedded.Enhanced Debug], *rfmci*, or *rfci* to ensure that the instructions in the “new” process execute in the “new” context.

Programming Note

For instruction-caused interrupts, in some cases it may be desirable for the operating system to emulate the instruction that caused the interrupt, while in other cases it may be desirable for the operating system not to emulate the instruction. The following list, while not complete, illustrates criteria by which decisions regarding emulation should be made. The list applies to general execution environments; it does not necessarily apply to special environments such as program debugging, bring-up, etc.

In general, the instruction should be emulated if:

- The interrupt is caused by a condition for which the instruction description (including related material such as the introduction to the section describing the instruction) implies that the instruction works correctly. Example: Alignment interrupt caused by *lmw* for which the storage operand is not aligned, or by *dcbz* or *dcbzep* for which the storage operand is in storage that is Write Through Required or Caching Inhibited.
- The instruction is an illegal instruction that should appear, to the program executing it, as if it were supported by the implementation. Example: Illegal Instruction type Program interrupt caused by an instruction that has been phased out of the architecture but is still used by some programs that the operating

system supports, or by an instruction that is in a category that the implementation does not support but is used by some programs that the operating system supports.

In general, the instruction should not be emulated if:

- The purpose of the instruction is to cause an interrupt. Example: System Call interrupt caused by *sc*.
- The interrupt is caused by a condition that is stated, in the instruction description, potentially to cause the interrupt. Example: Alignment interrupt caused by *lwarx* for which the storage operand is not aligned.
- The program is attempting to perform a function that it should not be permitted to perform. Example: Data Storage interrupt caused by *lwz* for which the storage operand is in storage that the program should not be permitted to access. (If the function is one that the program should be permitted to perform, the conditions that caused the interrupt should be corrected and the program re-dispatched such that the instruction will be re-executed. Example: Data Storage interrupt caused by *lwz* for which the storage operand is in storage that the program should be permitted to access but for which there currently is no TLB entry.)

7.6 Interrupt Definitions

Table 58 provides a summary of each interrupt type, the various exception types that may cause that interrupt type, the classification of the interrupt, which ESR (GESR) bits can be set, if any, which MSR bits can

mask the interrupt type and which Interrupt Vector Offset Register is used to specify that interrupt type's vector address.

1. If an expression of MSR bits is provided, the interrupt is masked if the expression evaluates to 0 and is enabled if the expression evaluates to 1.

Figure 58. Interrupt and Exception Types

Figure 58 Notes

- Although it is not specified, it is common for system implementations to provide, as part of the interrupt controller, independent mask and status bits for the various sources of Critical Input and External Input interrupts.
- Machine Check interrupts are a special case and are not classified as asynchronous nor synchronous. See Section 7.4.4 on page 1026.
- The Instruction Complete and Branch Taken debug events are only defined for $MSR_{DE}=1$ when in Internal Debug Mode ($DBCRO_{IDM}=1$). In other words, when in Internal Debug Mode with $MSR_{DE}=0$, then Instruction Complete and Branch Taken debug events cannot occur, and no DBSR status bits are set and no subsequent imprecise Debug interrupt will occur (see Section 10.4 on page 1078).

4. Machine Check status information is commonly provided as part of the system implementation, but is implementation-dependent.
5. In general, when an interrupt causes a particular ESR (GESR) bit or bits to be set (or cleared) as indicated in the table, it also causes all other ESR (GESR) bits to be cleared. There may be special rules regarding the handling of implementation-specific ESR (GESR) bits.

Legend:

[xxx] means ESR(GESR)_{xxx} could be set

[xxx,yyy] means either ESR(GESR)_{xxx} or ESR(GESR)_{yyy} may be set, but never both

(xxx,yyy) means either ESR(GESR)_{xxx} or ESR(GESR)_{yyy} will be set, but never both

{xxx,yyy} means either ESR(GESR)_{xxx} or ESR(GESR)_{yyy} will be set, or possibly both

xxx means ESR(GESR)_{xxx} is set

6. The precision of the Floating-point Enabled Exception type Program interrupt is controlled by the MSRR_{FE0,FE1} bits. When MSRR_{FE0,FE1}=0b01 or 0b10, the interrupt may be imprecise. When such a Program interrupt is taken, if the address saved in SRR0 is not the address of the instruction that caused the exception (i.e. the instruction that caused FPSCR_{FEX} to be set to 1), ESR_{PIE} is set to 1. When MSRR_{FE0,FE1}=0b11, the interrupt is precise. When MSRR_{FE0,FE1}=0b00, the interrupt is masked, and the interrupt will subsequently occur imprecisely if and when Floating-point Enabled Exception type Program interrupts are enabled by setting either or both of MSRR_{FE0,FE1}, and will also cause ESR_{PIE} to be set to 1. See Section 7.6.8. Also, exception status on the exact cause is available in the Floating-Point Status and Control Register (see Section 4.2.2 and Section 4.4 of Book I).

The precision of the Auxiliary Processor Enabled Exception type Program interrupt is implementation-dependent.
7. Auxiliary Processor exception status is commonly provided as part of the implementation.
8. Cache locking and cache locking exceptions are implementation-dependent.
9. Software must examine the instruction and the subject TLB entry to determine the exact cause of the interrupt.
10. If the Embedded.Enhanced Debug category is enabled, this interrupt is not a critical interrupt. DSRR0 and DSRR1 are used instead of CSRR0 and CSRR1.

7.6.1 Interrupt Fixed Offsets [Category: Embedded.Phased-In]

Figure 53 on page 1021 shows the 12-bit low-order effective address offset for each interrupt type. This value is the offset from the base address provided by either the IVPR (see Section 7.2.11) or the GIVPR (see Section 7.2.12).

offset	Interrupt
0x000	Machine Check

¹ MSR _{GS} is not modified by the occurrence of the interrupt except as described in Section 7.5.	

Figure 59. Interrupt Vector Offsets

7.6.2 Critical Input Interrupt

A Critical Input interrupt occurs when no higher priority exception exists (see Section 7.9 on page 1059), a Critical Input exception is presented to the interrupt mechanism, and MSR_{CE}=1. While the specific definition of a Critical Input exception is implementation-dependent, it would typically be caused by the activation of an asynchronous signal that is part of the system. Also, implementations may provide an alternative means (in addition to MSR_{CE}) for masking the Critical Input interrupt.

CSRR0, CSRR1, and MSR are updated as follows:

CSRR0 Set to the effective address of the next instruction to be executed.

CSRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to EPCR_{ICM}.

ME Unchanged.

DE Unchanged if category E.ED is supported; otherwise set to 0

All other defined MSR bits set to 0.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address IVPR_{0:51} || 0x020. Otherwise, instruction execution resumes at address IVPR_{0:47} || IVOR_{48:59} || 0b0000.

Programming Note

Software is responsible for taking any action(s) that are required by the implementation in order to clear any Critical Input exception status prior to re-enabling MSR_{CE} in order to avoid another, redundant Critical Input interrupt.

7.6.3 Machine Check Interrupt

A Machine Check interrupt occurs when no higher priority exception exists (see Section 7.9 on page 1059), a Machine Check exception is presented to the interrupt mechanism, and MSR_{ME}=1. The specific cause or causes of Machine Check exceptions are implementation-dependent, as are the details of the actions taken on a Machine Check interrupt.

If the Machine Check Extension is implemented, MCSRR0, MCSRR1, and MCSR are set, otherwise CSRR0, CSRR1, and ESR are set. The registers are updated as follows:

CSRR0/MCSRR0

Set to an instruction address. As closely as possible, set to the effective address of an instruction that was executing or about to be executed when the Machine Check exception occurred.

CSRR1/MCSRR1

Set to the contents of the MSR at the time of the interrupt.

MSR

CM	MSR _{CM} is set to EPCR _{CM} .
DE	Unchanged if category E.ED is supported; otherwise set to 0.

All other defined MSR bits set to 0.

ESR/MCSR

Implementation-dependent.

Instruction execution resumes at address IVPR_{0:47} || IVOR1_{48:59} || 0b0000.

If the Embedded.Hypervisor category is supported, a Machine Check interrupt caused by the existence of multiple direct TLB entries or multiple indirect TLB entries (or similar entries in implementation-specific translation caches) which translate a given virtual address (see Section 6.7.3) must occur while still in the context of the partition or hypervisor state that caused it. In these cases, the interrupt must be presented in a way that permits continuing execution. Treating the exception as instruction-caused allows these requirements to be achieved. Also, if the Embedded.Hypervisor category is supported, a Machine Check interrupt resulting from the following situations must be precise.

- Execution of an *External Process ID* instruction that has an operand that can be translated by multiple TLB entries.
- Execution of a *tlbivax* instruction that isn't a TLB invalidate all and there are multiple entries in a single thread's TLB array(s) that match the complete VPN.
- Execution of a *tlbilx* instruction with T=3 and there are multiple entries in the TLB array(s) that match the complete VPN.
- Execution of a *tlbsx* or *tlbsrx* instruction and there are multiple matching TLB entries.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported and Machine Check Interrupt Vector Prefix Register is supported, instruction execution resumes at address MCIVPR_{0:51} || 0x000. If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported and Machine Check Interrupt Vector Prefix Register is not implemented, instruction execution resumes at address IVPR_{0:51} || 0x000. If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address IVPR_{0:47} || IVOR1_{48:59} || 0b0000.

Programming Note

If a Machine Check interrupt is caused by an error in the storage subsystem, the storage subsystem may return incorrect data, that may be placed into registers and/or on-chip caches.

Programming Note

On implementations on which a Machine Check interrupt can be caused by referring to an invalid real address, executing a *dcbz*, *dcbzep*, or *dcbz* instruction can cause a delayed Machine Check interrupt by establishing in the data cache a block that is associated with an invalid real address. See Section 4.3 of Book II. A Machine Check interrupt can eventually occur if and when a subsequent attempt is made to write that block to main storage, for example as the result of executing an instruction that causes a cache miss for which the block is the target for replacement or as the result of executing a *dcbst*, *dcbstep*, *dcbf*, or *dcbfep* instruction.

7.6.4 Data Storage Interrupt

A Data Storage interrupt may occur when no higher priority exception exists (see Section 7.9 on page 1059) and a Data Storage exception is presented to the interrupt mechanism. A Data Storage exception is caused when any of the following exceptions arises during execution of an instruction:

Read Access Control exception

A Read Access Control exception is caused when one of the following conditions exist.

- While in user mode (MSR_{PR}=1), a *Load* or 'load-class' *Cache Management* instruction attempts to access a location in storage that is not user mode read enabled (i.e. page access control bit UR=0).
- While in supervisor mode (MSR_{PR}=0), a *Load* or 'load-class' *Cache Management* instruction attempts to access a location in storage that is not supervisor mode read enabled (i.e. page access control bit SR=0).

Write Access Control exception

A Write Access Control exception is caused when one of the following conditions exist.

- While in user mode (MSR_{PR}=1), a *Store* or 'store-class' *Cache Management* instruction attempts to access a location in storage that is not user mode write enabled (i.e. page access control bit UW=0).
- While in supervisor mode (MSR_{PR}=0), a *Store* or 'store-class' *Cache Management* instruction attempts to access a location in storage that is not supervisor mode write enabled (i.e. page access control bit SW=0).

Byte Ordering exception

A Byte Ordering exception may occur when the implementation cannot perform the data storage access in the byte order specified by the Endian storage attribute of the page being accessed.

Cache Locking exception

A Cache Locking exception may occur when the locked state of one or more cache lines has the potential to be altered. This exception is implementation-dependent.

Storage Synchronization exception

A Storage Synchronization exception will occur when an attempt is made to execute a *Load and Reserve* or *Store Conditional* instruction from or to a location that is Write Through Required or Caching Inhibited (if the interrupt does not occur then the instruction executes correctly: see Section 4.4.2 of Book II).

If a *stbcx.*, *sthcx.*, *stwcx.*, or *stdcx.* would not perform its store in the absence of a Data Storage interrupt, and either (a) the specified effective address refers to storage that is Write Through Required or Caching Inhibited, or (b) a non-conditional *Store* to the specified effective address would cause a Data Storage interrupt, it is implementation-dependent whether a Data Storage interrupt occurs.

Page Table Fault exception

A Page Table Fault exception is caused when a Page Table translation occurs for a data access due to a *Load*, *Store* or *Cache Management* instruction and the Page Table Entry that is accessed is invalid (PTE Valid bit = 0).

TLB Ineligible exception

A TLB Ineligible exception is caused when a Page Table translation occurs for a data access due to a *Load*, *Store* or *Cache Management* instruction and any of the following conditions are true.

- The only TLB entries that can be used to hold the translation for the virtual address have $IPROT=1$
- No TLB array can be loaded from the Page Table for the page size specified by the PTE.
- The PTE_{ARPN} is treated as an LPN (The Embedded.Hypervisor category is supported) and there is no TLB array that meets all the following conditions.
 - The TLB array supports the page size specified by the PTE.
 - The TLB array can be loaded from the Page Table ($TLBnCFG_{PT} = 1$).

If the Embedded.Hypervisor category is supported, an Data Storage interrupt resulting from a TLB Ineligible exception is always directed to hypervisor state regardless of the setting of $EPCR_{DSIGS}$.

Virtualization Fault exception [Category: Embedded.Hypervisor]

A Virtualization Fault exception will occur when a *Load*, *Store*, or *Cache Management* Instruction attempts to access a location in storage that has the Virtualization Fault (VF) bit set. A Data Storage interrupt resulting from a Virtualization Fault exception is always directed

to hypervisor state regardless of the setting of $EPCR_{DSIGS}$.

Instructions *lswx* or *stswx* with a length of zero, *icbt*, *dcbt*, *dcbtstp*, *dcbtst*, *dcbtstep*, or *dcba* cannot cause a Data Storage interrupt, regardless of the effective address.

Programming Note

The *icbi*, *icbiep*, *icbt*, *icbtls* and *icblc* instructions are treated as *Loads* from the addressed byte with respect to address translation and protection. These *Instruction Cache Management* instructions use MSR_{DS} , not MSR_{IS} , to determine translation for their operands. Instruction Storage exceptions and Instruction TLB Miss exceptions are associated with the ‘fetching’ of instructions not with the ‘execution’ of instructions. Data Storage exceptions and Data TLB Miss exceptions are associated with the ‘execution’ of *Instruction Cache Management* instructions. One exception to the above is that *icbtls* and *icblc* only cause a Data Storage exception if they have neither execute access nor read access.

When a Data Storage interrupt occurs, the thread suppresses the execution of the instruction causing the Data Storage exception.

If category Embedded.Hypervisor is not supported or if category Embedded.Hypervisor is supported and the interrupt is directed to hypervisor state, $SRR0$, $SRR1$, MSR , $DEAR$, and ESR are updated as follows:

SRR0 Set to the effective address of the instruction causing the Data Storage interrupt.

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to $EPCR_{ICM}$.
 CE, ME,
 DE Unchanged.

All other defined MSR bits set to 0.

DEAR Set to the effective address of a byte that is both within the range of the bytes being accessed by the *Storage Access* or *Cache Management* instruction, and within the page whose access caused the Data Storage exception.

ESR

FP Set to 1 if the instruction causing the interrupt is a floating-point load or store; otherwise set to 0.

ST Set to 1 if the instruction causing the interrupt is a *Store* or ‘store-class’ *Cache Management* instruction; otherwise set to 0.

DLK _{0:1}	Set to an implementation-dependent value due to a Cache Locking exception causing the interrupt.
AP	Set to 1 if the instruction causing the interrupt is an Auxiliary Processor load or store; otherwise set to 0.
BO	Set to 1 if the instruction caused a Byte Ordering exception; otherwise set to 0.
TLBI	Set to 1 if a TLB Ineligible exception occurred during a Page Table translation for the instruction causing the interrupt; otherwise set to 0.
PT	If a Page Table Fault or Read or Write Access Control exception occurred during a Page Table translation for the instruction causing the interrupt, then PT is set to 1 if no TLB entry was created from the Page Table and is set to an implementation-dependent value if a TLB entry was created. See Section 6.7.4 for rules about TLB updates. If no Page Table Fault or Read or Write Access Control exception occurred during a Page Table translation for the instruction causing the interrupt, set to 0.
SPV	Set to 1 if the instruction causing the interrupt is a SPE operation or a Vector operation; otherwise set to 0.
VLEMI	Set to 1 if the instruction causing the interrupt resides in VLE storage.
EPID	Set to 1 if the instruction causing the interrupt is an External Process ID instruction; otherwise set to 0.

All other defined ESR bits are set to 0.

If category Embedded.Hypervisor is supported and the interrupt is directed to guest supervisor state GSRR0, GSRR1, GDEAR, and GESR are set in place of SRR0, SRR1, DEAR, and ESR, respectively. The MSR is set as follows:

MSR

CM MSR_{CM} is set to EPCR_{GICM}.
CE, ME, WE, GS, DE
Unchanged.

Bits in the MSR corresponding to set bits in the MSRP register are left unchanged.

All other defined MSR bits set to 0.

The following is a prioritized listing of the various exceptions which cause a Data Storage interrupt and the corresponding ESR bit, if applicable. Even though multiple of these exceptions may occur, at most one of the following exceptions is reported in the ESR.

1. Cache Locking <ECL>: DLK_{0:1}
2. Page Table Fault <E.PT>: PT
3. Virtualization Fault <E.HV>
4. TLB Ineligible <E.PT>: TLBI

5. Byte Ordering: BO
6. Read Access or Write Access: If the exception occurred during a Page Table translation, PT <E.PT>

Programming Note

Since some Data Storage exceptions are not mutually exclusive, system software may need to examine the TLB entry or the Page Table entry accessed by the data storage access in order to determine whether additional exceptions may have also occurred.

If Category Embedded.Hypervisor is supported and the interrupt is directed to the guest state, instruction execution resumes at the address given by one of the following.

- GIVPR_{0:47} || GIVOR_{248:59} || 0b0000 if IVORs [Category: Embedded.Phased-Out] are supported.
- GIVPR_{0:51} || 0x060 if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported.

Otherwise, instruction execution resumes at the address given by one of the following.

- IVPR_{0:47} || IVOR_{248:59} || 0b0000 if IVORs [Category: Embedded.Phased-Out] are supported.
- IVPR_{0:51} || 0x060 if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported.

7.6.5 Instruction Storage Interrupt

An Instruction Storage interrupt occurs when no higher priority exception exists (see Section 7.9 on page 1059) and an Instruction Storage exception is presented to the interrupt mechanism. An Instruction Storage exception is caused when any of the following exceptions arises during execution of an instruction:

Execute Access Control exception

An Execute Access Control exception is caused when one of the following conditions exist.

- While in user mode (MSR_{PR}=1), an instruction fetch attempts to access a location in storage that is not user mode execute enabled (i.e. page access control bit UX=0).
- While in supervisor mode (MSR_{PR}=0), an instruction fetch attempts to access a location in storage that is not supervisor mode execute enabled (i.e. page access control bit SX=0).

Byte Ordering exception

A Byte Ordering exception may occur when the implementation cannot perform the instruction fetch in the byte order specified by the Endian storage attribute of the page being accessed.

Page Table Fault exception

A Page Table Fault exception is caused when a Page Table translation occurs for an instruction fetch and the Page Table Entry that is accessed is invalid (Valid bit = 0).

TLB Ineligible exception

A TLB Ineligible exception is caused when a Page Table translation occurs for an instruction fetch and any of the following conditions are true.

- The only TLB entries that can be used to hold the translation for the virtual address have $IPROT=1$
- No TLB array can be loaded from the Page Table for the page size specified by the PTE.
- The PTE_{ARPN} is treated as an LPN (The Embedded.Hypervisor category is supported) and there is no TLB array that meets all the following conditions.
 - The TLB array supports the page size specified by the PTE.
 - The TLB array can be loaded from the Page Table ($TLBnCFG_{PT} = 1$).

If the Embedded.Hypervisor category is supported, an Instruction Storage interrupt resulting from a TLB Ineligible exception is always directed to hypervisor state regardless of the setting of $EPCR_{ISIGS}$.

When an Instruction Storage interrupt occurs, the thread suppresses the execution of the instruction causing the Instruction Storage exception.

If category Embedded.Hypervisor is not supported or if category Embedded.Hypervisor is supported and the interrupt is directed to hypervisor state, $SRR0$, $SRR1$, MSR, and ESR are updated as follows:

$SRR0$, $SRR1$, MSR, and ESR are updated as follows:

SRR0 Set to the effective address of the instruction causing the Instruction Storage interrupt.

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to $EPCR_{ICM}$.
CE, ME, DE
Unchanged.

All other defined MSR bits set to 0.

ESR

BO Set to 1 if the instruction fetch caused a Byte Ordering exception; otherwise set to 0.

TLBI Set to 1 if a TLB Ineligible exception occurred during a Page Table translation for the instruction causing the interrupt; otherwise set to 0.

PT If a Page Table Fault or an Execute Access Control exception occurred during a Page Table translation for the instruction causing

the interrupt, then PT is set to 1 if no TLB entry was created from the Page Table and is set to an implementation-dependent value if a TLB entry was created. See Section 6.7.4 for rules about TLB updates. If no Page Table Fault or Execute Access Control exception occurred during a Page Table translation for the instruction causing the interrupt, set to 0.

VLEMI Set to 1 if the instruction causing the interrupt resides in VLE storage.

All other defined ESR bits are set to 0.

If category Embedded.Hypervisor is supported and the interrupt is directed to guest supervisor state, $GSRR0$, $GSRR1$, and GESR are set in place of $SRR0$, $SRR1$, and ESR, respectively. The MSR is set as follows:

MSR

CM MSR_{CM} is set to $EPCR_{GICM}$.
CE, ME, WE, GS, DE
Unchanged.

Bits in the MSR corresponding to set bits in the MSRP register are left unchanged.

All other defined MSR bits set to 0.

The following is a prioritized listing of the various exceptions which cause a Instruction Storage interrupt and the corresponding ESR bit, if applicable. Even though multiple of these exceptions may occur, at most one of the following exceptions is reported in the ESR.

1. Page Table Fault <E.PT>: PT
2. TLB Ineligible <E.PT>: TLBI
3. Byte Ordering exception: BO
4. Execute Access: If the exception occurred during a Page Table translation, PT <E.PT>

Programming Note

Since some Instruction Storage exceptions are not mutually exclusive, system software may need to examine the TLB entry or the Page Table entry accessed by the data storage access in order to determine whether additional exceptions may have also occurred.

If Category Embedded.Hypervisor is supported and the interrupt is directed to the guest state, instruction execution resumes at the address given by one of the following.

- $GIVPR_{0:47} \parallel GIVOR_{348:59} \parallel 0b0000$ if IVORs [Category: Embedded.Phased-Out] are supported.
- $GIVPR_{0:51} \parallel 0x080$ if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported.

Otherwise, instruction execution resumes at the address given by one of the following.

- $IVPR_{0:47} \parallel IVOR_{348:59} \parallel 0b0000$ if IVORs [Category: Embedded.Phased-Out] are supported.
- $IVPR_{0:51} \parallel 0x080$ if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported.

7.6.6 External Input Interrupt

An External Input interrupt occurs when no higher priority exception exists (see Section 7.9 on page 1059), an External Input exception is presented to the interrupt mechanism, and the interrupt is enabled. While the specific definition of an External Input exception is implementation-dependent, it would typically be caused by the activation of an asynchronous signal that is part of the processing system. Also, implementations may provide an alternative means (in addition to the enabled criteria) for masking the External Input interrupt.

If category Embedded.Hypervisor is supported, External Input interrupts are enabled if:

$$(EPCR_{EXTGS} = 0) \ \& \ ((MSR_{GS} = 1) \mid (MSR_{EE} = 1))$$

or

$$(EPCR_{EXTGS} = 1) \ \& \ (MSR_{GS} = 1) \ \& \ (MSR_{EE} = 1)$$

Otherwise, External Input interrupts are enabled if $MSR_{EE} = 1$.

If category Embedded.Hypervisor is not supported or if category Embedded.Hypervisor is supported and the interrupt is directed to hypervisor state, $SRR0$, $SRR1$, and MSR are updated as follows:

SRR0 Set to the effective address of the next instruction to be executed.

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to $EHSR_{ICM}$.
 CE, ME, DE,
 Unchanged.

All other defined MSR bits set to 0.

If category Embedded.Hypervisor is supported and the interrupt is directed to the guest supervisor state, $GSRR0$ and $GSRR1$ are set in place of $SRR0$ and $SRR1$, respectively. The MSR is set as follows:

MSR

CM MSR_{CM} is set to $EPCR_{GICM}$.
 CE, ME, WE, GS, DE
 Unchanged.

Bits in the MSR corresponding to set bits in the $MSRP$ register are left unchanged.

All other defined MSR bits set to 0.

If Category Embedded.Hypervisor is supported and the interrupt is directed to the guest state, instruction exe-

cutio resumes at the address given by one of the following.

- $GIVPR_{0:47} \parallel GIVOR_{448:59} \parallel 0b0000$ if IVORs [Category: Embedded.Phased-Out] are supported.
- $GIVPR_{0:51} \parallel 0x0A0$ if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported.

Otherwise, instruction execution resumes at the address given by one of the following.

- $IVPR_{0:47} \parallel IVOR_{448:59} \parallel 0b0000$ if IVORs [Category: Embedded.Phased-Out] are supported.

$IVPR_{0:51} \parallel 0x0A0$ if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported.

Programming Note

Software is responsible for taking whatever action(s) are required by the implementation in order to clear any External Input exception status prior to re-enabling MSR_{EE} in order to avoid another, redundant External Input interrupt.

7.6.7 Alignment Interrupt

An Alignment interrupt occurs when no higher priority exception exists (see Section 7.9 on page 1059) and an Alignment exception is presented to the interrupt mechanism. An Alignment exception may be caused when the implementation cannot perform a data storage access for one of the following reasons:

- The operand of a single-register *Load* or *Store* is not aligned.
- The instruction is a *Load Multiple* or *Store Multiple*, or a *Move Assist* for which the length of the storage operand is not zero.
- The operand of *dcbz* or *dcbzep* is in storage that is Write Through Required or Caching Inhibited, or one of these instructions is executed in an implementation that has either no data cache or a Write Through data cache or the line addressed by the instruction cannot be established in the cache because the cache is disabled or locked.
- The operand of a *Store*, except *Store Conditional*, or *Store String* for which the length of the storage operand is zero, is in storage that is Write-Through Required.

For *lmw* and *stmw* with an operand that is not word-aligned, and for *Load and Reserve* and *Store Conditional* instructions with an operand that is not aligned, an implementation may yield boundedly undefined results instead of causing an Alignment interrupt. A *Store Conditional* to Write Through Required storage may either cause a Data Storage interrupt, cause an Alignment interrupt, or correctly execute the instruction. For all other cases listed above, an implementation may execute the instruction correctly instead of causing an Alignment interrupt. (For *dcbz* or *dcbzep*, 'correct' execution means setting each byte of the block in main storage to 0x00.)

Programming Note

The architecture does not support the use of an unaligned effective address by *Load and Reserve* and *Store Conditional* instructions. If an Alignment interrupt occurs because one of these instructions specifies an unaligned effective address, the Alignment interrupt handler must not attempt to emulate the instruction, but instead should treat the instruction as a programming error.

When an Alignment interrupt occurs, the thread suppresses the execution of the instruction causing the Alignment exception.

SRR0, SRR1, MSR, DEAR, and ESR are updated as follows:

SRR0 Set to the effective address of the instruction causing the Alignment interrupt.

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to EPCR_{ICM}.
CE, ME, DE Unchanged

CE, ME, DE, ICM Unchanged.

All other defined MSR bits set to 0.

DEAR Set to the effective address of a byte that is both within the range of the bytes being accessed by the *Storage Access* or *Cache Management* instruction, and within the page whose access caused the Alignment exception.

ESR

FP Set to 1 if the instruction causing the interrupt is a floating-point load or store; otherwise set to 0.

ST Set to 1 if the instruction causing the interrupt is a *Store*; otherwise set to 0.

AP Set to 1 if the instruction causing the interrupt is an Auxiliary Processor load or store; otherwise set to 0.

SPV Set to 1 if the instruction causing the interrupt is a SPE operation or a Vector operation; otherwise set to 0.

VLEMI Set to 1 if the instruction causing the interrupt resides in VLE storage.

EPID Set to 1 if the instruction causing the interrupt is an External Process ID instruction; otherwise set to 0.

All other defined ESR bits are set to 0.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address IVPR_{0:51} || 0x0C0. Otherwise,

instruction execution resumes at address IVPR_{0:47} || IVOR5_{48:59} || 0b0000.

7.6.8 Program Interrupt

A Program interrupt occurs when no higher priority exception exists (see Section 7.9 on page 1059), a Program exception is presented to the interrupt mechanism, and, for Floating-point Enabled exception, MSR_{FE0,FE1} are non-zero. A Program exception is caused when any of the following exceptions arises during execution of an instruction:

Floating-point Enabled exception

A Floating-point Enabled exception is caused when FPSCR_{FEX} is set to 1 by the execution of a floating-point instruction that causes an enabled exception, including the case of a *Move To FPSCR* instruction that causes an exception bit and the corresponding enable bit both to be 1. Note that in this context, the term ‘enabled exception’ refers to the enabling provided by control bits in the Floating-Point Status and Control Register. See Section 4.2.2 of Book I.

Auxiliary Processor Enabled exception

The cause of an Auxiliary Processor Enabled exception is implementation-dependent.

Illegal Instruction exception

An Illegal Instruction exception *does* occur when execution is attempted of any of the following kinds of instructions.

- a reserved-illegal instruction
- when MSR_{PR}=1 (user mode), an *mtspr* or *mfspir* that specifies an spr value with spr₅=0 (user-mode accessible) that represents an unimplemented Special Purpose Register

An Illegal Instruction exception *may* occur when execution is attempted of any of the following kinds of instructions. If the exception does not occur, the alternative is shown in parentheses.

- an instruction that is in invalid form (boundedly undefined results)
- an *lswx* instruction for which register RA or register RB is in the range of registers to be loaded (boundedly undefined results)
- a defined instruction that is not implemented by the implementation (Unimplemented Operation exception)

Privileged Instruction exception

A Privileged Instruction exception occurs when MSR_{PR}=1 and execution is attempted of any of the following kinds of instructions.

- a privileged instruction

- an *mtspr* or *mfspr* instruction that specifies an spr value with $\text{spr}_5=1$

Trap exception

A Trap exception occurs when any of the conditions specified in a *Trap* instruction are met and the exception is not also enabled as a Debug interrupt. If enabled as a Debug interrupt (i.e. $\text{DBCRO}_{\text{TRAP}}=1$, $\text{DBCRO}_{\text{IDM}}=1$, and $\text{MSR}_{\text{DE}}=1$), then a Debug interrupt will be taken instead of the Program interrupt.

Unimplemented Operation exception

An Unimplemented Operation exception *may* occur when execution is attempted of a defined instruction that is not implemented by the implementation. Otherwise an Illegal Instruction exception occurs.

An Unimplemented Operation exception *may* also occur when the thread is in 32-bit mode and execution is attempted of an instruction that is part of the 64-Bit category. Otherwise the instruction executes normally.

SRR0, SRR1, MSR, and ESR are updated as follows:

SRR0 For all Program interrupts except an Enabled exception when in one of the imprecise modes (see Section 4.2.1 on page 903) or when a disabled exception is subsequently enabled, set to the effective address of the instruction that caused the Program interrupt.

For an imprecise Enabled exception, set to the effective address of the excepting instruction or to the effective address of some subsequent instruction. If it points to a subsequent instruction, that instruction has not been executed, and ESR_{PIE} is set to 1. If a subsequent instruction is an *sync* or *isync*, SRR0 will point at the *sync* or *isync* instruction, or at the following instruction.

If $\text{FPSCR}_{\text{FEX}}=1$ but both $\text{MSR}_{\text{FE0}}=0$ and $\text{MSR}_{\text{FE1}}=0$, an Enabled exception type Program interrupt will occur imprecisely prior to or at the next synchronizing event if these MSR bits are altered by any instruction that can set the MSR so that the expression

$$(\text{MSR}_{\text{FE0}} \mid \text{MSR}_{\text{FE1}}) \ \& \ \text{FPSCR}_{\text{FEX}}$$

is 1. When this occurs, SRR0 is loaded with the address of the instruction that would have executed next, not with the address of the instruction that modified the MSR causing the interrupt, and ESR_{PIE} is set to 1.

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to EPCR_{ICM} .
CE, ME, DE Unchanged

All other defined MSR bits set to 0.

ESR

PIL Set to 1 if an Illegal Instruction exception type Program interrupt; otherwise set to 0
PPR Set to 1 if a Privileged Instruction exception type Program interrupt; otherwise set to 0
PTR Set to 1 if a Trap exception type Program interrupt; otherwise set to 0
PUO Set to 1 if an Unimplemented Operation exception type Program interrupt; otherwise set to 0
FP Set to 1 if the instruction causing the interrupt is a floating-point instruction; otherwise set to 0.
PIE Set to 1 if a Floating-point Enabled exception type Program interrupt, and the address saved in SRR0 is not the address of the instruction causing the exception (i.e. the instruction that caused $\text{FPSCR}_{\text{FEX}}$ to be set); otherwise set to 0.
AP Set to 1 if the instruction causing the interrupt is an Auxiliary Processor instruction; otherwise set to 0.
SPV Set to 1 if the instruction causing the interrupt is a SPE operation or a Vector operation; otherwise set to 0.
VLEMI Set to 1 if the instruction causing the interrupt resides in VLE storage.

All other defined ESR bits are set to 0.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address $\text{IVPR}_{0:51} \mid 0x0E0$. Otherwise, instruction execution resumes at address $\text{IVPR}_{0:47} \mid \text{IVOR}_{648:59} \mid 0b0000$.

7.6.9 Floating-Point Unavailable Interrupt

A Floating-Point Unavailable interrupt occurs when no higher priority exception exists (see Section 7.9 on page 1059), an attempt is made to execute a floating-point instruction (i.e. any instruction listed in Section 4.6 of Book I), and $\text{MSR}_{\text{FP}}=0$.

When a Floating-Point Unavailable interrupt occurs, the hardware suppresses the execution of the instruction causing the Floating-Point Unavailable interrupt.

SRR0, SRR1, and MSR are updated as follows:

SRR0 Set to the effective address of the instruction that caused the interrupt.

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to EPCR_{ICM}.
CE, ME, DE
Unchanged

All other defined MSR bits set to 0.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address IVPR_{0:51} || 0x100. Otherwise, instruction execution resumes at address IVPR_{0:47} || IVOR_{748:59} || 0b0000.

7.6.10 System Call Interrupt

A System Call interrupt occurs when no higher priority exception exists (see Section 7.9 on page 1059) and a *System Call (sc)* instruction is executed.

If category Embedded.Hypervisor is not supported or if category Embedded.Hypervisor is supported and the interrupt is directed to hypervisor state, SRR0, SRR1, and MSR are updated as follows:

SRR0 Set to the effective address of the instruction *after* the *sc* instruction.

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to EPCR_{ICM}.
VLEMI Set to 1 if the instruction causing the interrupt resides in VLE storage.
CE, ME, DE
Unchanged.

All other defined MSR bits set to 0.

If category Embedded.Hypervisor is supported and the interrupt is directed to guest supervisor state (MSR_{GS} = 1), GSRR0 and GSRR1 are set in place of SRR0 and SRR1, respectively. The MSR is set as follows:

MSR

CM MSR_{CM} is set to EPCR_{GICM}.
CE, ME, WE, GS, DE
Unchanged.

Bits in the MSR corresponding to set bits in the MSRP register are left unchanged.

All other defined MSR bits set to 0.

If Category Embedded.Hypervisor is supported and the interrupt is directed to the guest state, instruction execution resumes at the address given by one of the following.

- GIVPR_{0:47} || GIVOR_{848:59} || 0b0000 if IVORs [Category: Embedded.Phased-Out] are supported.
- GIVPR_{0:51} || 0x120 if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported.

Otherwise, instruction execution resumes at the address given by one of the following.

- IVPR_{0:47} || IVOR_{848:59} || 0b0000 if IVORs [Category: Embedded.Phased-Out] are supported.
- IVPR_{0:51} || 0x120 if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported.

7.6.11 Auxiliary Processor Unavailable Interrupt

An Auxiliary Processor Unavailable interrupt occurs when no higher priority exception exists (see Section 7.9 on page 1059), an attempt is made to execute an Auxiliary Processor instruction (including Auxiliary Processor loads, stores, and moves), the target Auxiliary Processor is present on the implementation, and the Auxiliary Processor is configured as unavailable. Details of the Auxiliary Processor, its instruction set, and its configuration are implementation-dependent. See User's Manual for the implementation.

When an Auxiliary Processor Unavailable interrupt occurs, the hardware suppresses the execution of the instruction causing the Auxiliary Processor Unavailable interrupt.

Registers SRR0, SRR1, and MSR are updated as follows:

SRR0 Set to the effective address of the instruction that caused the interrupt.

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to EPCR_{ICM}.
CE, ME, DE
Unchanged

All other defined MSR bits set to 0.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address IVPR_{0:51} || 0x140. Otherwise, instruction execution resumes at address IVPR_{0:47} || IVOR_{948:59} || 0b0000.

7.6.12 Decrementer Interrupt

A Decrementer interrupt occurs when no higher priority interrupt exists (see Section 7.9 on page 1059), a Decrementer exception exists (TSR_{DIS}=1), and the exception is enabled. If category Embedded.Hypervisor is supported, the interrupt is enabled by TCR[DIE]=1 and (MSR_{EE}=1 or MSR_{GS}=1). Otherwise, the interrupt is enabled by TCR_{DIE}=1 and MSR_{EE}=1. See Section 9.3 on page 1069.

Programming Note

MSR_{EE} also enables the External Input and Fixed-Interval Timer interrupts.

SRR0, SRR1, MSR, and TSR are updated as follows:

SRR0 Set to the effective address of the next instruction to be executed.

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to EPCR_{ICM}.
CE, ME, DE Unchanged

All other defined MSR bits set to 0.

TSR (See Section 9.5.1 on page 1072.)

DIS Set to 1.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address IVPR_{0:51} || 0x160. Otherwise, instruction execution resumes at address IVPR_{0:47} || IVOR10_{48:59} || 0b0000.

Programming Note

Software is responsible for clearing the Decrementer exception status prior to re-enabling the MSR_{EE} bit in order to avoid another redundant Decrementer interrupt. To clear the Decrementer exception, the interrupt handling routine must clear TSR_{DIS}. Clearing is done by writing a word to TSR using *mtspr* with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write-data to the TSR is not direct data, but a mask. A 1 causes the bit to be cleared, and a 0 has no effect.

7.6.13 Fixed-Interval Timer Interrupt

A Fixed-Interval Timer interrupt occurs when no higher priority exception exists (see Section 7.9 on page 1059), a Fixed-Interval Timer exception exists (TSR_{FIS}=1), and the exception is enabled. If category Embedded.Hypervisor is supported, the interrupt is enabled by TCR_{FIE}=1 and MSR_{GS}=1. See Section 9.6 on page 1073.

Programming Note

MSR_{EE} also enables the External Input and Decrementer interrupts.

SRR0, SRR1, MSR, and TSR are updated as follows:

SRR0 Set to the effective address of the next instruction to be executed.

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to EPCR_{ICM}.

CE, ME, DE

Unchanged.

All other defined MSR bits set to 0.

TSR (See Section 9.5.1 on page 1072.)

FIS Set to 1

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address IVPR_{0:51} || 0x180. Otherwise, instruction execution resumes at address IVPR_{0:47} || IVOR11_{48:59} || 0b0000.

Programming Note

Software is responsible for clearing the Fixed-Interval Timer exception status prior to re-enabling the MSR_{EE} bit in order to avoid another redundant Fixed-Interval Timer interrupt. To clear the Fixed-Interval Timer exception, the interrupt handling routine must clear TSR_{FIS}. Clearing is done by writing a word to TSR using *mtspr* with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write-data to the TSR is not direct data, but a mask. A 1 causes the bit to be cleared, and a 0 has no effect.

7.6.14 Watchdog Timer Interrupt

A Watchdog Timer interrupt occurs when no higher priority exception exists (see Section 7.9 on page 1059), a Watchdog Timer exception exists (TSR_{WIS}=1), and the exception is enabled. If category Embedded.Hypervisor is supported, the interrupt is enabled by TCR_{WIE}=1 and (MSR_{CE} = 1 or MSR_{GS}=1). Otherwise, the interrupt is enabled by TCR_{WIE}=1 and MSR_{CE}=1. See Section 9.7 on page 1073.

Programming Note

MSR_{CE} also enables the Critical Input interrupt.

CSRR0, CSRR1, MSR, and TSR are updated as follows:

CSRR0 Set to the effective address of the next instruction to be executed.

CSRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to EPCR_{ICM}.

ME Unchanged.

DE Unchanged if category E.ED is supported; otherwise set to 0.

All other defined MSR bits set to 0.

TSR (See Section 9.5.1 on page 1072.)

WIS Set to 1.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution

resumes at address $IVPR_{0:51} \parallel 0x1A0$. Otherwise, instruction execution resumes at address $IVPR_{0:47} \parallel IVOR_{12:48:59} \parallel 0b0000$.

Programming Note

Software is responsible for clearing the Watchdog Timer exception status prior to re-enabling the MSR_{CE} bit in order to avoid another redundant Watchdog Timer interrupt. To clear the Watchdog Timer exception, the interrupt handling routine must clear TSR_{WIS} . Clearing is done by writing a word to TSR using *mtspr* with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write-data to the TSR is not direct data, but a mask. A 1 causes the bit to be cleared, and a 0 has no effect.

7.6.15 Data TLB Error Interrupt

A Data TLB Error interrupt occurs when no higher priority exception exists (see Section 7.9 on page 1059) and any of the following Data TLB Error exceptions is presented to the interrupt mechanism.

TLB Miss exception

Caused when the virtual address associated with a data storage access does not match any valid entry in the TLB as specified in Section 6.7.2 on page 949.

If a *stbcx.*, *sthcx.*, *stwcx.*, or *stdcx.* would not perform its store in the absence of a Data Storage interrupt, and a non-conditional *Store* to the specified effective address would cause a Data Storage interrupt, it is implementation dependent whether a Data Storage interrupt occurs.

When a Data TLB Error interrupt occurs, the hardware suppresses the execution of the instruction causing the Data TLB Error interrupt.

If category Embedded.Hypervisor is not supported or if category Embedded.Hypervisor is supported and the interrupt is directed to hypervisor state, $SRR0$, $SRR1$, MSR , $DEAR$, and ESR are updated as follows:

SRR0 Set to the effective address of the instruction causing the Data TLB Error interrupt

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to $EHSR_{ICM}$.
CE, ME, DE

Unchanged.

All other defined MSR bits set to 0.

DEAR Set to the effective address of a byte that is both within the range of the bytes being accessed by the *Storage Access* or *Cache*

Management instruction, and within the page whose access caused the Data TLB Error exception.

ESR

ST Set to 1 if the instruction causing the interrupt is a *Store*, *dcbi*, *dcbz*, or *dcbzep* instruction; otherwise set to 0.

FP Set to 1 if the instruction causing the interrupt is a floating-point load or store; otherwise set to 0.

AP Set to 1 if the instruction causing the interrupt is an Auxiliary Processor load or store; otherwise set to 0.

SPV Set to 1 if the instruction causing the interrupt is a SPE operation or a Vector operation; otherwise set to 0.

VLEMI Set to 1 if the instruction causing the interrupt resides in VLE storage.

EPID Set to 1 if the instruction causing the interrupt is an External Process ID instruction; otherwise set to 0.

All other defined ESR bits are set to 0.

If category Embedded.Hypervisor is supported and the interrupt is directed to guest supervisor state, $GSRR0$, $GSRR1$, $GDEAR$, and $GESR$ are set in place of $SRR0$, $SRR1$, $DEAR$, and ESR , respectively. The MSR is set as follows:

MSR

CM MSR_{CM} is set to $EPCR_{GICM}$.
CE, ME, WE, GS, DE
Unchanged.

Bits in the MSR corresponding to set bits in the $MSRP$ register are left unchanged.

All other defined MSR bits set to 0.

If Category Embedded.Hypervisor is supported and the interrupt is directed to the guest state, instruction execution resumes at the address given by one of the following.

- $GIVPR_{0:47} \parallel GIVOR_{13:48:59} \parallel 0b0000$ if IVORs [Category: Embedded.Phased-Out] are supported.
- $GIVPR_{0:51} \parallel 0x1C0$ if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported.

Otherwise, instruction execution resumes at the address given by one of the following.

- $IVPR_{0:47} \parallel IVOR_{13:48:59} \parallel 0b0000$ if IVORs [Category: Embedded.Phased-Out] are supported.
- $IVPR_{0:51} \parallel 0x1C0$ if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported.

7.6.16 Instruction TLB Error Interrupt

An Instruction TLB Error interrupt occurs when no higher priority exception exists (see Section 7.9 on

page 1059) and any of the following Instruction TLB Error exceptions is presented to the interrupt mechanism.

TLB Miss exception

Caused when the virtual address associated with an instruction fetch does not match any valid entry in the TLB as specified in Section 6.7.2 on page 949.

When an Instruction TLB Error interrupt occurs, the hardware suppresses the execution of the instruction causing the Instruction TLB Miss exception.

If category Embedded.Hypervisor is not supported or if category Embedded.Hypervisor is supported and the interrupt is directed to hypervisor state, SRR0, SRR1, and MSR are updated as follows:

SRR0 Set to the effective address of the instruction causing the Instruction TLB Error interrupt.

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to EPCR_{ICM}.
CE, ME, DE Unchanged.

All other defined MSR bits set to 0.

If category Embedded.Hypervisor is supported and the interrupt is directed to guest supervisor state, GSRR0 and GSRR1 are set in place of SRR0 and SRR1, respectively. The MSR is set as follows:

MSR

CM MSR_{CM} is set to EPCR_{GICM}.
CE, ME, WE, GS, DE Unchanged.

Bits in the MSR corresponding to set bits in the MSRP register are left unchanged.

All other defined MSR bits set to 0.

If Category Embedded.Hypervisor is supported and the interrupt is directed to the guest state, instruction execution resumes at the address given by one of the following.

- GIVPR_{0:47} || GIVOR_{14:48:59} || 0b0000 if IVORs [Category: Embedded.Phased-Out] are supported.
- GIVPR_{0:51} || 0x1E0 if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported.

Otherwise, instruction execution resumes at the address given by one of the following.

- IVPR_{0:47} || IVOR_{14:48:59} || 0b0000 if IVORs [Category: Embedded.Phased-Out] are supported.
- IVPR_{0:51} || 0x1E0 if Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported.

7.6.17 Debug Interrupt

A Debug interrupt occurs when no higher priority exception exists (see Section 7.9 on page 1059), a Debug exception exists in the DBSR, and Debug interrupts are enabled (DBCRO_{IDM}=1 and MSR_{DE}=1). A Debug exception occurs when a Debug Event causes a corresponding bit in the DBSR to be set. See Section 10.5.

If the Embedded.Enhanced Debug category is not supported or is supported and is not enabled, CSRR0, CSRR1, MSR, and DBSR are updated as follows. If the Embedded.Enhanced Debug category is supported and is enabled, DSRR0 and DSRR1 are updated as specified below and CSRR0 and CSRR1 are not changed. The means by which the Embedded.Enhanced Debug category is enabled is implementation-dependent.

CSRR0 or **DSRR0** [Category: Embedded.Enhanced Debug]

For Debug exceptions that occur while Debug interrupts are enabled (DBCRO_{IDM}=1 and MSR_{DE}=1), CSRR0 is set as follows:

- For Instruction Address Compare (IAC1, IAC2, IAC3, IAC4), Data Address Compare (DAC1R, DAC1W, DAC2R, DAC2W), Data Value Compare (DVC1, DVC2), Trap (TRAP), or Branch Taken (BRT) debug exceptions, set to the address of the instruction causing the Debug interrupt.
- For Instruction Complete (ICMP) debug exceptions, set to the address of the instruction that would have executed after the one that caused the Debug interrupt.
- For Unconditional Debug Event (UDE) debug exceptions, set to the address of the instruction that would have executed next if the Debug interrupt had not occurred.
- For Interrupt Taken (IRPT) debug exceptions, set to the interrupt vector value of the interrupt that caused the Interrupt Taken debug event.
- For Return From Interrupt (RET) debug exceptions, set to the address of the *rfi* instruction that caused the Debug interrupt.
- For Critical Interrupt Taken (CRPT) debug exceptions, DSRR0 is set to the address of the first instruction of the critical interrupt handler. CSRR0 is unaffected.
- For Critical Interrupt Return (CRET) debug exceptions, DSRR0 is set to the address of the *rfi* instruction that

caused the Debug interrupt. See Section 10.4.10, “Critical Interrupt Return Debug Event [Category: Embedded.Enhanced Debug]”.

For Debug exceptions that occur while Debug interrupts are disabled ($DBCR0_{IDM}=0$ or $MSR_{DE}=0$), a Debug interrupt will occur at the next synchronizing event if $DBCR0_{IDM}$ and MSR_{DE} are modified such that they are both 1 and if the Debug exception Status is still set in the DBSR. When this occurs, $CSRR0$ or $DSRR0$ [Category:Embedded.Enhanced Debug] is set to the address of the instruction that would have executed next, not with the address of the instruction that modified the Debug Control Register 0 or MSR and thus caused the interrupt.

CSRR1 or **DSRR1** [Category: Embedded.Enhanced Debug]

Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to $EPCR_{ICM}$.
ME Unchanged

All other supported MSR bits set to 0.

DBSR Set to indicate type of Debug Event (see Section 10.5.2)

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address $IVPR_{0:51} \parallel 0x040$. Otherwise, instruction execution resumes at address $IVPR_{0:47} \parallel IVOR_{15_{48:59}} \parallel 0b0000$.

7.6.18 SPE/Embedded Floating-Point/Vector Unavailable Interrupt [Categories: SPE.Embedded Float Scalar Double, SPE.Embedded Float Vector, Vector]

The SPE/Embedded Floating-Point/Vector Unavailable interrupt occurs when no higher priority exception exists, and an attempt is made to execute an SPE, SPE.Embedded Float Scalar Double, SPE.Embedded Float Vector, or Vector instruction and $MSR_{SPV} = 0$.

When an Embedded Floating-Point Unavailable interrupt occurs, the hardware suppresses the execution of the instruction causing the exception.

$SRR0$, $SRR1$, MSR, and ESR are updated as follows:

SRR0 Set to the effective address of the instruction causing the Embedded Floating-Point Unavailable interrupt.

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to $EPCR_{ICM}$.
CE, ME,DE Unchanged

ESR

SPV Set to 1.
VLEMI Set to 1 if the instruction causing the interrupt resides in VLE storage.

All other defined ESR bits are set to 0.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address $IVPR_{0:51} \parallel 0x200$. Otherwise, instruction execution resumes at address $IVPR_{0:47} \parallel IVOR_{32_{48:59}} \parallel 0b0000$.

Programming Note

This interrupt is also used by the Signal Processing Engine in the same manner. It should be used by software to determine if the application is using the upper 32 bits of the GPRs in a 32-bit implementation and thus be required to save and restore them on context switch.

7.6.19 Embedded Floating-Point Data Interrupt

[Categories: SPE.Embedded Float Scalar Double, SPE.Embedded Float Scalar Single, SPE.Embedded Float Vector]

The Embedded Floating-Point Data interrupt occurs when no higher priority exception exists (see Section 7.9) and an Embedded Floating-Point Data exception is presented to the interrupt mechanism. The Embedded Floating-Point Data exception causing the interrupt is indicated in the SPEFSCR; these exceptions include Embedded Floating-Point Invalid Operation/Input Error (FINV, FINVH), Embedded Floating-Point Divide By Zero (FDBZ, FDBZH), Embedded Floating-Point Overflow (FOV, FOVH), and Embedded Floating-Point Underflow (FUNF, FUNFH)

When an Embedded Floating-Point Data interrupt occurs, the hardware suppresses the execution of the instruction causing the exception.

SRR0, SRR1, MSR, and ESR are updated as follows:

SRR0 Set to the effective address of the instruction causing the Embedded Floating-Point Data interrupt.

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to EPCR_{ICM}.
CE, ME, DE

Unchanged

VLEMI Set to 1 if the instruction causing the interrupt resides in VLE storage.

All other defined MSR bits set to 0.

ESR

SPV Set to 1.

All other defined ESR bits are set to 0.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address IVPR_{0:51} || 0x220. Otherwise, instruction execution resumes at address IVPR_{0:47} || IVOR33_{48:59} || 0b0000.

7.6.20 Embedded Floating-Point Round Interrupt

[Categories: SPE.Embedded Float Scalar Double, SPE.Embedded Float Scalar Single, SPE.Embedded Float Vector]

The Embedded Floating-Point Round interrupt occurs when no higher priority exception exists (see Section 7.9 on page 1059), SPEFSCR_{FINXE} is set to 1, and any of the following occurs:

- the unrounded result of an *Embedded Floating-Point* operation is not exact
- an overflow occurs and overflow exceptions are disabled (FOVF or FOVFH is set to 1 and FOVFE is set to 0)
- an underflow occurs and underflow exceptions are disabled (FUNF is set to 1 and FUNFE is set to 0).

The value of SPEFSCR_{FINXS} is 1, indicating that one of the above exceptions has occurred, and additional information about the exception is found in SPEFSCR_{FGH FG FXH FX}.

When an Embedded Floating-Point Round interrupt occurs, the hardware completes the execution of the instruction causing the exception and writes the result to the destination register prior to taking the interrupt.

SRR0, SRR1, MSR, and ESR are updated as follows:

SRR0 Set to the effective address of the instruction following the instruction causing the Embedded Floating-Point Round interrupt.

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to EPCR_{ICM}.
CE, ME, DE

Unchanged

All other defined MSR bits set to 0.

ESR

SPV Set to 1.

VLEMI Set to 1 if the instruction causing the interrupt resides in VLE storage.

All other defined ESR bits are set to 0.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address IVPR_{0:51} || 0x240. Otherwise, instruction execution resumes at address IVPR_{0:47} || IVOR34_{48:59} || 0b0000.

Programming Note

If an implementation does not support \pm Infinity rounding modes and the rounding mode is set to be +Infinity or -Infinity, an Embedded Floating-Point Round interrupt occurs after every *Embedded Floating-Point* instruction for which rounding might occur regardless of the value of FINXE, provided no higher priority exception exists.

When an Embedded Floating-Point Round interrupt occurs, the unrounded (truncated) result of an inexact high or low element is placed in the target register. If only a single element is inexact, the other exact element is updated with the correctly rounded result, and the FG and FX bits corresponding to the other exact element will both be 0.

The bits FG (FGH) and FX (FXH) are provided so that an interrupt handler can round the result as it desires. FG (FGH) is the value of the bit immediately to the right of the least significant bit of the destination format mantissa from the infinitely precise intermediate calculation before rounding. FX (FXH) is the value of the 'or' of all the bits to the right of the FG (FGH) of the destination format mantissa from the infinitely precise intermediate calculation before rounding.

7.6.21 Performance Monitor Interrupt [Category: Embedded.Performance Monitor]

The Performance Monitor interrupt is part of the optional Performance Monitor facility; see Appendix D.

7.6.22 Processor Doorbell Interrupt [Category: Embedded.Processor Control]

A Processor Doorbell Interrupt occurs when no higher priority exception exists, a Processor Doorbell exception is present, and the interrupt is enabled ($MSR_{EE}=1$). Processor Doorbell exceptions are generated when DBELL messages (see Chapter 11) are received and accepted by the thread.

If category Embedded.Hypervisor is supported, the interrupt is enabled if $MSR_{GS} = 1$ or $MSR_{EE}=1$.

SRR0, SRR1 and MSR are updated as follows:

- SRR0** Set to the effective address of the next instruction to be executed.
- SRR1** Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to $EPCR_{ICM}$.

CE, ME, DE

Unchanged.

All other defined MSR bits set to 0.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address $IVPR_{0:51} \parallel 0x280$. Otherwise, instruction execution resumes at address $IVPR_{0:47} \parallel IVOR36_{48:59} \parallel 0b0000$.

7.6.23 Processor Doorbell Critical Interrupt [Category: Embedded.Processor Control]

A Processor Doorbell Critical Interrupt occurs when no higher priority exception exists, a Processor Doorbell Critical exception is present, and the interrupt is enabled ($MSR_{CE}=1$). Processor Doorbell Critical exceptions are generated when DBELL_CRIT messages (see Chapter 11) are received and accepted by the thread.

If category Embedded.Hypervisor is supported, the interrupt is enabled if $MSR_{GS} = 1$ or $MSR_{CE}=1$.

CSRR0, CSRR1 and MSR are updated as follows:

- CSRR0** Set to the effective address of the next instruction to be executed.
- CSRR1** Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to $EPCR_{ICM}$.

ME Unchanged.

DE Unchanged if category E.ED is supported, otherwise set to 0

All other defined MSR bits set to 0.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address $IVPR_{0:51} \parallel 0x2A0$. Otherwise, instruction execution resumes at address $IVPR_{0:47} \parallel IVOR37_{48:59} \parallel 0b0000$.

7.6.24 Guest Processor Doorbell Interrupt [Category: Embedded.Hypervisor, Embedded.Processor Control]

A Guest Processor Doorbell Interrupt occurs when no higher priority exception exists, a Guest Processor Doorbell exception is present, and the interrupt is enabled ($MSR_{GS}=1$ and $MSR_{EE}=1$). Guest Processor Doorbell exceptions are generated when G_DBELL messages (see Chapter 11) are received and accepted by the thread.

GSRR0, GSRR1 and MSR are updated as follows:

GSRR0 Set to the effective address of the next instruction to be executed.

GSRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to EPCR_{ICM}.
CE, ME, DE
Unchanged.

All other defined MSR bits set to 0.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address IVPR_{0:51} || 0x2C0. Otherwise, instruction execution resumes at address IVPR_{0:47} || IVOR38_{48:59} || 0b0000.

Programming Note

Guest Processor Doorbell interrupts are used by the hypervisor to be notified when the guest operating system has set MSR_{EE} to 1. This allows the hypervisor to reflect base class interrupts to the guest at a time when the guest is ready to accept them (MSR_{GS}=1 and MSR_{EE}=1).

Programming Note

Some guest operating systems running on a hypervisor may use *lazy* interrupt blocking. That is, when the operating system wants to block interrupts at the interrupt controller, it does not actually perform the blocking operation, but instead sets a value in memory that represents the level at which interrupts are to be blocked. When an actual interrupt occurs, this value is consulted to determine if the interrupt should have been blocked. If so, the current interrupt level that is to be blocked is set in the interrupt controller and the interrupt handling code returns without acknowledging the interrupt. When interrupts are unblocked at a later time, the interrupt will be reasserted by the interrupt controller. When a hypervisor is taking external interrupts and then reflecting them to a guest, the hypervisor must acknowledge the interrupt before reflecting it to the guest since the external interrupt will occur again once MSR_{GS} = 1 regardless of the state of MSR_{EE}.

To emulate the behavior required for lazy interrupt blocking by the guest, the hypervisor should execute another *msgsnd* instruction specifying a Guest Processor Doorbell at the time that it is reflecting the interrupt to the guest. When the guest performs its interrupt acknowledge (a hypercall or writing to an interrupt controller register emulated by the hypervisor), the hypervisor can execute a *msgclr* to clear a pending message if there are no other interrupts to be reflected to the guest.

7.6.25 Guest Processor Doorbell Critical Interrupt [Category: Embedded.Hypervisor,Embedded.Processor Control]

A Guest Processor Doorbell Critical Interrupt occurs when no higher priority exception exists, a Guest Processor Doorbell Critical exception is present, and the interrupt is enabled ($MSR_{GS} = 1$ and $MSR_{CE}=1$). Guest Processor Doorbell Critical exceptions are generated when `G_DBELL_CRIT` messages (see Chapter 11) are received and accepted by the thread.

CSRR0, CSRR1 and MSR are updated as follows:

CSRR0 Set to the effective address of the next instruction to be executed.

CSRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to $EPCR_{ICM}$.
ME Unchanged.
DE Unchanged if category E.ED is supported, otherwise set to 0

All other defined MSR bits set to 0.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address $IVPR_{0:51} \parallel 0x2E0$. Otherwise, instruction execution resumes at address $IVPR_{0:47} \parallel IVOR_{39:48:59} \parallel 0b0000$.

Programming Note

Guest Processor Doorbell Critical interrupts are used by the hypervisor to be notified when the guest operating system has set MSR_{CE} to 1. This allows the hypervisor to reflect critical class interrupts to the guest at a time when the guest is ready to accept them ($MSR_{GS}=1$ and $MSR_{CE}=1$).

7.6.26 Guest Processor Doorbell Machine Check Interrupt [Category: Embedded.Hypervisor,Embedded.Processor Control]

A Guest Processor Doorbell Machine Check Interrupt occurs when no higher priority exception exists, a Guest Processor Doorbell Machine Check exception is present, and the interrupt is enabled ($MSR_{GS} = 1$ and $MSR_{ME}=1$). Guest Processor Doorbell Machine Check exceptions are generated when `G_DBELL_MC` messages (see Chapter 11) are received and accepted by the thread.

CSRR0, CSRR1 and MSR are updated as follows:

CSRR0 Set to the effective address of the next instruction to be executed.

CSRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to $EPCR_{ICM}$.
ME Unchanged.
DE Unchanged if category E.ED is supported, otherwise set to 0

All other defined MSR bits set to 0.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address $IVPR_{0:51} \parallel 0x2E0$. Otherwise, instruction execution resumes at address $IVPR_{0:47} \parallel IVOR_{39:48:59} \parallel 0b0000$.

Programming Note

Guest Processor Doorbell Machine Check interrupts are used by the hypervisor to be notified when the guest operating system has set MSR_{ME} to 1. This allows the hypervisor to reflect machine check class interrupts to the guest at a time when the guest is ready to accept them ($MSR_{GS}=1$ and $MSR_{ME}=1$).

Programming Note

Guest Processor Doorbell Critical interrupts and Guest Processor Doorbell Machine Check interrupts share the same IVOR. Hypervisor software can differentiate between the two interrupts by comparing whether CE or ME is set in CSRR1 and which interrupt class is to be reflected.

7.6.27 Embedded Hypervisor System Call Interrupt [Category: Embedded.Hypervisor]

An Embedded Hypervisor System Call interrupt occurs when no higher priority exception exists (see Section 7.9) and a *System Call* (`sc`) instruction with $LEV = 1$ is executed.

SRR0, SRR1, and MSR are updated as follows:

SRR0 Set to the effective address of the instruction *after* the `sc` instruction.

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to $EPCR_{ICM}$.
VLEMI Set to 1 if the instruction causing the interrupt resides in VLE storage.
CE, ME, DE

Unchanged.

All other defined MSR bits set to 0.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address $IVPR_{0:51} \parallel 0x300$. Otherwise, instruction execution resumes at address $IVPR_{0:47} \parallel IVOR40_{48:59} \parallel 0b0000$.

7.6.28 Embedded Hypervisor Privilege Interrupt [Category: Embedded.Hypervisor]

An Embedded Hypervisor Privilege interrupt occurs when no higher priority exception exists (see Section 7.9 on page 1059) and an Embedded Hypervisor Privilege exception is presented to the exception mechanism.

An Embedded Hypervisor Privilege exception occurs when $MSR_{GS} = 1$ and $MSR_{PR} = 0$ and execution is attempted of any of the following:

- a hypervisor-privileged instruction
- an *mtspr* or *mfspr* instruction that specifies an SPR that is hypervisor privileged
- a *tlbwe* instruction and category Embedded.Hypervisor.LRAT is not implemented.
- a *tlbwe*, *tlbsrx*, or *tlbilx* instruction and $EPCR_{DGTMI} = 1$
- a *tlbwe* instruction that attempts to write a TLB entry for which $TLB_V = 1$ and $TLB_{IPROT} = 1$ when $MAS0_{WQ} = 0b00$
- a *tlbwe* instruction that attempts to write a TLB entry when $MAS1_V = 1$, $MAS1_{IPROT} = 1$, and $MAS0_{WQ} = 0b00$
- a *mtpmr* or *mfpmr* instruction and $MSRP_{PMMP} = 1$
- a *Cache Locking* instruction and $MSRP_{UCLEP} = 1$

An Embedded Hypervisor Privilege exception may occur for the following implementation dependent reasons when $MSR_{GS} = 1$ and $MSR_{PR} = 0$ and execution is attempted of any of the following:

- a *tlbwe* instruction that attempts to write a TLB entry for which $TLB_V = 0$ and $TLB_{IPROT} = 1$ when $MAS0_{WQ} = 0b00$
- a *tlbwe* instruction that attempts to write a TLB entry when $MAS1_V = 0$, $MAS1_{IPROT} = 1$, and $MAS0_{WQ} = 0b00$
- a *tlbwe* instruction that attempts to write a TLB entry for which $TLB_{IPROT} = 1$ when $MAS0_{WQ} = 0b01$
- a *tlbwe* instruction that attempts to write a TLB entry when $MAS1_{IPROT} = 1$, and $MAS0_{WQ} = 0b01$
- a *tlbwe* instruction that attempts to write a TLB entry when $MAS0_{HES} = 0$
- a *tlbwe* instruction that attempts to write a TLB entry to an array that is disallowed by the implementation
- an implementation dependent instruction or SPR which is hypervisor privileged

An Embedded Hypervisor Privilege exception also occurs when execution is attempted of an *ehpriv* instruction, regardless of the state of the thread.

Execution of the instruction causing the interrupt is suppressed and $SRR0$, $SRR1$, and MSR are updated as follows:

SRR0 Set to the effective address of the instruction causing the Embedded Hypervisor Privilege interrupt.

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to $EPCR_{ICM}$.

VLEMI Set to 1 if the instruction causing the interrupt resides in VLE storage.

CE, ME, DE
Unchanged.

All other defined MSR bits set to 0.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address $IVPR_{0:51} \parallel 0x320$. Otherwise, instruction execution resumes at address $IVPR_{0:47} \parallel IVOR41_{48:59} \parallel 0b0000$.

7.6.29 LRAT Error Interrupt [Category: Embedded.Hypervisor.LRAT]

An LRAT Error interrupt occurs when no higher priority exception exists (see Section 7.9 on page 1059) and an LRAT Miss exception is presented to the interrupt mechanism.

An LRAT Miss exception is caused by either of the following.

- A *tlbwe* instruction is executed in guest supervisor state and the logical page number (RPN specified by $MAS7$ and $MAS3$ and page size specified by $MAS1_{TSIZE}$) does not match any valid entry in the LRAT.
- A Page Table translation is performed and the associated PTE_{ARPN} is to be treated as an LPN (the Embedded.Hypervisor category is supported) and the logical page number (RPN based on PTE_{ARPN} and page size specified by PTE_{PS}) does not match any valid entry in the LRAT.

When an LRAT Error interrupt occurs, the hardware suppresses the execution of the instruction causing the LRAT Error interrupt.

$SRR0$, $SRR1$, MSR , ESR , and $LPER$ are updated as follows:

SRR0 Set to the effective address of the instruction causing the LRAT Error interrupt.

SRR1 Set to the contents of the MSR at the time of the interrupt.

MSR

CM MSR_{CM} is set to EPCR_{ICM}.
CE, ME, DE Unchanged.

All other defined MSR bits are set to 0.

DEAR

If the LRAT Error interrupt occurred for a Page Table translation, set to the effective address of a byte that is both within the range of the bytes being accessed by the *Storage Access* or *Cache Management* instruction, and within the page whose access caused the LRAT Miss exception. Otherwise, undefined.

ESR

FP Set to 1 if the instruction causing the interrupt is a floating-point load or store and the translation of the operand address causes the LRAT Miss exception; otherwise set to 0.

ST Set to 1 if the instruction causing the interrupt is a *Store* or 'store-class' *Cache Management* instruction and the translation of the operand address causes the LRAT Miss exception; otherwise set to 0.

AP Set to 1 if the instruction causing the interrupt is an Auxiliary Processor load or store and the translation of the operand address causes the LRAT Miss exception; otherwise set to 0.

SPV Set to 1 if the instruction causing the interrupt is a SPE operation or a Vector operation, the instruction is a *Load* or *Store*, and the translation of the operand address causes the LRAT Miss exception; otherwise set to 0.

DATA Set to 1 if the interrupt is due to an LRAT miss resulting from a Page Table translation of a *Load*, *Store* or *Cache Management* operand address; otherwise set to 0.

TLBI Set to 1 if a TLB Ineligible exception occurred during a Page Table translation for the instruction causing the interrupt; otherwise set to 0.

PT Set to 1 if the cause of the interrupt is an LRAT miss exception on a Page Table translation. Set to 0 if the cause of the interrupt is an LRAT miss exception on a *tlbwe*.

VLEMI Set to 1 if the instruction causing the interrupt resides in VLE storage, the instruction is a *Load*, *Store*, or *Cache Management* instruction, and the translation of the operand address causes the LRAT Miss exception.

EPID Set to 1 if the instruction causing the interrupt is an External Process ID instruction, the instruction is a *Load*, *Store*, or *Cache Management* instruction, and the translation of the operand address causes the LRAT Miss exception; otherwise set to 0.

All other defined ESR bits are set to 0.

LPER

Set to the values of the ARPN and PS fields from the PTE that was used to translate a virtual address for an instruction fetch, *Load*, *Store* or *Cache Management* instruction that caused an LRAT Error interrupt as a result of an LRAT Miss exception.

If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address IVPR_{0:47} || 0x0340. Otherwise, instruction execution resumes at address IVPR_{0:47} || IVOR42_{48:59} || 0b0000.

7.7 Partially Executed Instructions

In general, the architecture permits load and store instructions to be partially executed, interrupted, and then to be restarted from the beginning upon return from the interrupt. Unaligned *Load* and *Store* instructions, or *Load Multiple*, *Store Multiple*, *Load String*, and *Store String* instructions may be broken up into multiple, smaller accesses, and these accesses may be performed in any order. In order to guarantee that a particular load or store instruction will complete without being interrupted and restarted, software must mark the storage being referred to as Guarded, and must use an elementary (non-string or non-multiple) load or store that is aligned on an operand-sized boundary.

In order to guarantee that *Load* and *Store* instructions can, in general, be restarted and completed correctly without software intervention, the following rules apply when an execution is partially executed and then interrupted:

- For an elementary *Load*, no part of the target register RT or FRT, will have been altered.
- For ‘with update’ forms of *Load* or *Store*, the update register, register RA, will not have been altered.

On the other hand, the following effects are permissible when certain instructions are partially executed and then restarted:

- For any *Store*, some of the bytes at the target storage location may have been altered (if write access to that page in which bytes were altered is permitted by the access control mechanism). In addition, for *Store Conditional* instructions, CR0 has been set to an undefined value, and it is undefined whether the reservation has been cleared.
- For any *Load*, some of the bytes at the addressed storage location may have been accessed (if read access to that page in which bytes were accessed is permitted by the access control mechanism).
- For *Load Multiple* or *Load String*, some of the registers in the range to be loaded may have been altered. Including the addressing registers (RA, and possibly RB) in the range to be loaded is a programming error, and thus the rules for partial execution do not protect against overwriting of these registers.

In no case will access control be violated.

As previously stated, the only load or store instructions that are guaranteed to not be interrupted after being partially executed are elementary, aligned, guarded loads and stores. All others may be interrupted after being partially executed. The following list identifies the specific instruction types for which interruption after partial execution may occur, as well as the specific interrupt types that could cause the interruption:

1. Any *Load* or *Store* (except elementary, aligned, guarded):
 - Any asynchronous interrupt
 - Machine Check
 - Program (Imprecise Mode Floating-Point Enabled)
 - Program (Imprecise Mode Auxiliary Processor Enabled)
2. Unaligned elementary *Load* or *Store*, or any multiple or string:
 - All of the above listed under item 1, plus the following:
 - Data Storage (if the access crosses a protection boundary)
 - Debug (Data Address Compare, Data Value Compare)
3. *mtcrf* may also be partially executed due to the occurrence of any of the interrupts listed under item 1 at the time the *mtcrf* was executing.
 - All instructions prior to the *mtcrf* have completed execution. (Some storage accesses generated by these preceding instructions may not have completed.)
 - No subsequent instruction has begun execution.
 - The *mtcrf* instruction (the address of which was saved in SRR0/CSRR0/MCSRR0/DSRR0 [Category: Embedded.Enhanced.Debug] at the occurrence of the interrupt), may appear not to have begun or may have partially executed.

7.8 Interrupt Ordering and Masking

It is possible for multiple exceptions to exist simultaneously, each of which could cause the generation of an interrupt. Furthermore, for interrupts classes other than the Machine Check interrupt and critical interrupts, the architecture does not provide for reporting more than one interrupt of the same class (unless the Embedded.Enhanced Debug category is supported). Therefore, the architecture defines that interrupts are ordered with respect to each other, and provides a masking mechanism for certain persistent interrupt types.

When an interrupt is masked (disabled), and an event causes an exception that would normally generate the interrupt, the exception *persists* as a *status* bit in a register (which register depends upon the exception type). However, no interrupt is generated. Later, if the interrupt is enabled (unmasked), and the exception status has not been cleared by software, the interrupt due to the original exception event will then finally be generated.

All asynchronous interrupts can be masked. In addition, certain synchronous interrupts can be masked. An example of such an interrupt is the Floating-Point Enabled exception type Program interrupt. The execution of a floating-point instruction that causes the $FPSCR_{FEX}$ bit to be set to 1 is considered an exception event, regardless of the setting of $MSR_{FE0,FE1}$. If $MSR_{FE0,FE1}$ are both 0, then the Floating-Point Enabled exception type of Program interrupt is masked, but the exception persists in the $FPSCR_{FEX}$ bit. Later, if the $MSR_{FE0,FE1}$ bits are enabled, the interrupt will finally be generated.

The architecture enables implementations to avoid situations in which an interrupt would cause the state information (saved in Save/Restore Registers) from a previous interrupt to be overwritten and lost. In order to do this, the architecture defines interrupt classes in a hierarchical manner. At each interrupt class, hardware automatically disables any further interrupts associated with the interrupt class by masking the interrupt enable in the MSR when the interrupt is taken. In addition, each interrupt class masks the interrupt enable in the MSR for each lower class in the hierarchy. The hierar-

chy of interrupt classes is as follows from highest to lowest:

Interrupt Class	MSR Enables Cleared	Save/Restore Registers
Machine Check	ME,DE, CE, EE	MSRR0/1
Debug ¹	DE,CE,EE	DSRR0/1
Critical	CE,EE	CSRR0/1
Base	EE	SRR0/1
Guest <E.HV>	EE	GSRR0/1

¹ The Debug interrupt class is Category: E.ED.

Note: MSR_{DE} may be cleared when a critical interrupt occurs if Category: E.ED is not supported.

Figure 60. Interrupt Hierarchy

[Category: Embedded.Hypervisor]

The masking of interrupts is affected by MSR_{GS} and whether the interrupt is directed to the guest supervisor state or the hypervisor state. In general, interrupts directed to the hypervisor state (with the exception of Guest Processor Doorbell type interrupts), are enabled if $MSR_{GS} = 1$ regardless of the value of other MSR enables. Interrupts directed to the guest supervisor state are enabled if the associated MSR enables are set and $MSR_{GS} = 1$.

If the Embedded.Enhanced Debug category is not supported (or is supported and is not enabled), then the Debug interrupt becomes a Critical class interrupt and all critical class interrupts will clear DE, CE, and EE in the MSR.

Base Class interrupts that occur as a result of precise exceptions are not masked by the EE bit in the MSR and any such exception that occurs prior to software saving the state of SRR0/1 in a base class exception handler will result in a situation that could result in the loss of state information.

This first step of the hardware clearing the MSR enable bits lower in the hierarchy shown in Figure 60 prevents any subsequent asynchronous interrupts from overwriting the Save/Restore Registers (SRR0/SRR1, CSRR0/CSRR1, MCSRR0/MCSRR1, or DSRR0/DSRR1 [Category: Embedded.Enhanced Debug]), prior to software being able to save their contents. Hardware also automatically clears, on any interrupt, $MSR_{PR,FP,FE0,FE1,IS,DS}$. The clearing of these bits assists in the avoidance of subsequent interrupts of certain other types. However, *guaranteeing* that interrupt classes lower in the hierarchy do not occur and thus do not overwrite the Save/Restore Registers (SRR0/SRR1, CSRR0/CSRR1, DSRR0/DSRR1 [Category: Embedded.Enhanced Debug], or MCSRR0/MCSRR1) also requires the cooperation of system software. Specifically, system software must avoid the exe-

cution of instructions that could cause (or enable) a subsequent interrupt, if the contents of the Save/Restore Registers (SRR0/SRR1, CSRR0/CSRR1, DSRR0/DSRR1 [Category: Embedded.Enhanced Debug]), or MCSRR0/MCSRR1) have not yet been saved.

7.8.1 Guidelines for System Software

The following list identifies the actions that system software must avoid, prior to having saved the Save/Restore Registers' contents:

- Re-enabling an interrupt class that is at the same or a lower level in the interrupt hierarchy. This includes the following actions:
 - Re-enabling of MSR_{EE}
 - Re-enabling of MSR_{CE,EE} in critical class interrupt handlers, and if the Embedded.Enhanced Debug category is not supported, re-enabling of MSR_{DE}.
 - Category: Embedded.Enhanced Debug: Re-enabling of MSR_{CE,EE,DE} in Debug class interrupt handlers
 - Re-enabling of MSR_{EE,CE,DE,ME} in Machine Check interrupt handlers.
- Branching (or sequential execution) to addresses for which any of the following conditions are true.
 - The address is not mapped by the TLB or the Page Table or is mapped without UX=1 or SX=1 permission.
 - Both the Embedded.Hypervisor.LRAT and the Embedded.Page.Table category are supported, MSR_{GS}=1, and the effective address is mapped by the Page Table but the LPN is not mapped by the LRAT.

This prevents Instruction Storage, LRAT Error, and Instruction TLB Error interrupts.

- *Load, Store or Cache Management* instructions to addresses for which any of the following conditions are true.
 - The address is not mapped by the TLB or the Page Table or is mapped without the required access permissions.
 - Both the Embedded.Hypervisor.LRAT and the Embedded.Page.Table category are supported, MSR_{GS}=1, and the effective address is mapped by the Page Table but the LPN is not mapped by the LRAT.

This prevents Data Storage, LRAT Error, and Data TLB Error interrupts.

- Execution of any floating-point instruction

This prevents Floating-Point Unavailable interrupts. Note that this interrupt would occur upon the

execution of any floating-point instruction, due to the automatic clearing of MSR_{FP}. However, even if software were to re-enable MSR_{FP} floating-point instructions must still be avoided in order to prevent Program interrupts due to various possible Program interrupt exceptions (Floating-Point Enabled, Unimplemented Operation).

- Re-enabling of MSR_{PR}

This prevents Privileged Instruction exception type Program interrupts. Alternatively, software could re-enable MSR_{PR}, but avoid the execution of any privileged instructions.
- Execution of any Auxiliary Processor instruction

This prevents Auxiliary Processor Unavailable interrupts, and Auxiliary Processor Enabled type and Unimplemented Operation type Program interrupts.
- Execution of any Illegal instructions

This prevents Illegal Instruction exception type Program interrupts.
- Execution of any instruction that could cause an Alignment interrupt

This prevents Alignment interrupts. Included in this category are any string or multiple instructions, and any unaligned elementary load or store instructions. See Section 7.6.7 on page 1039 for a complete list of instructions that may cause Alignment interrupts.

It is not necessary for hardware or software to avoid interrupts higher in the interrupt hierarchy (see Figure 60 on page 1055) from within interrupt handlers (and hence, for example, hardware does not automatically clear MSR_{CE,ME,DE} upon a base class interrupt), since interrupts at each level of the hierarchy use different pairs of Save/Restore Registers to save the instruction address and MSR (i.e. SRR0/SRR1 for base class interrupts, and MCSRR0/MCSRR1, DSRR0/DSRR1 [Category: Embedded.Enhanced Debug], or CSRR0/CSRR1 for non-base class interrupts). The converse, however, is not true. That is, hardware and software must cooperate in the avoidance of interrupts lower in the hierarchy from occurring within interrupt handlers, even though these interrupts use different Save/Restore Register pairs. This is because the interrupt higher in the hierarchy may have occurred from within an interrupt handler for an interrupt lower in the hierarchy prior to the interrupt handler having saved the Save/Restore Registers. Therefore, within an interrupt handler, Save/Restore Registers for all interrupts lower in the hierarchy may contain data that is necessary to the system software.

7.8.2 Interrupt Order

The following is a prioritized listing of the various enabled interrupts for which exceptions might exist simultaneously:

1. Synchronous (Non-Debug) Interrupts:
 - Data Storage
 - Instruction Storage
 - Alignment
 - Program
 - Embedded Hypervisor Privilege <E.HV>
 - Floating-Point Unit Unavailable
 - Auxiliary Processor Unavailable
 - Embedded Floating-Point Unavailable
[SP.Category: SP.Embedded Float_*]
 - SPE/Embedded Floating-Point/Vector
Unavailable
 - Embedded Floating-Point Data [Category:
SP.Embedded Float_*]
 - Embedded Floating-Point Round [Category:
SP.Embedded Float_*]
 - System Call
 - Embedded Hypervisor System Call <E.HV>
 - Data TLB Error
 - Instruction TLB Error
 - LRAT Error <E.HV.LRAT>

Only one of the above types of synchronous interrupts may have an existing exception generating it at any given time. This is guaranteed by the exception priority mechanism (see Section 7.9 on page 1059) and the requirements of the Sequential Execution Model.

2. Machine Check
3. Guest Processor Doorbell Machine Check <E.PC,E.HV>
4. Debug
5. Critical Input
6. Watchdog Timer
7. Processor Doorbell Critical <E.PC> Category: Embedded.Processor Control
8. Guest Processor Doorbell Critical <E.HV> Category: Embedded.Processor Control
9. External Input Category: Embedded.Processor Control
10. Fixed-Interval Timer Category: Embedded.Processor Control
11. Decrementer Category: Embedded.Processor Control
12. Processor Doorbell <E.PC> Category: Embedded.Processor Control
13. Guest Processor Doorbell <E.PC,E.HV>
14. Embedded Performance Monitor

Even though, as indicated above, the base, synchronous exception types listed under item 1 are generated with higher priority than the non-base interrupt classes listed in items 2-6, the fact is that these base class interrupts will immediately be followed by the highest

priority existing interrupt in items 2-5, without executing any instructions at the base class interrupt handler. This is because the base interrupt classes do not automatically disable the MSR mask bits for the interrupts listed in 2-5. In all other cases, a particular interrupt class from the above list will automatically disable any subsequent interrupts of the same class, as well as all other interrupt classes that are listed below it in the priority order.

7.9 Exception Priorities

All synchronous (precise and imprecise) interrupts are reported in program order, as required by the Sequential Execution Model. The one exception to this rule is the case of multiple synchronous imprecise interrupts. Upon a synchronizing event, all previously executed instructions are required to report any synchronous imprecise interrupt-generating exceptions, and the interrupt will then be generated with all of those exception types reported cumulatively, in both the ESR, and any status registers associated with the particular exception type (e.g. the Floating-Point Status and Control Register).

For any single instruction attempting to cause multiple exceptions for which the corresponding synchronous interrupt types are enabled, this section defines the priority order by which the instruction will be permitted to cause a *single* enabled exception, thus generating a particular synchronous interrupt. Note that it is this exception priority mechanism, along with the requirement that synchronous interrupts be generated in program order, that guarantees that at any given time, there exists for consideration only one of the synchronous interrupt types listed in item 1 of Section 7.8.2 on page 1058. The exception priority mechanism also prevents certain debug exceptions from existing in combination with certain other synchronous interrupt-generating exceptions.

Because unaligned *Load* and *Store* instructions, or *Load Multiple*, *Store Multiple*, *Load String*, and *Store String* instructions may be broken up into multiple, smaller accesses, and these accesses may be performed in any order. The exception priority mechanism applies to each of the multiple storage accesses in the order they are performed by the implementation.

This section does not define the permitted setting of multiple exceptions for which the corresponding interrupt types are disabled. The generation of exceptions for which the corresponding interrupt types are disabled will have no effect on the generation of other exceptions for which the corresponding interrupt types are enabled. Conversely, if a particular exception for which the corresponding interrupt type is enabled is shown in the following sections to be of a higher priority than another exception, it will prevent the setting of that other exception, independent of whether that other exception's corresponding interrupt type is enabled or disabled.

Except as specifically noted, only one of the exception types listed for a given instruction type will be permitted to be generated at any given time. The priority of the exception types are listed in the following sections ranging from highest to lowest, within each instruction type.

Programming Note

Some exception types may even be mutually exclusive of each other and could otherwise be considered the same priority. In these cases, the exceptions are listed in the order suggested by the sequential execution model.

7.9.1 Exception Priorities for Defined Instructions

7.9.1.1 Exception Priorities for Defined Floating-Point Load and Store Instructions

The following prioritized list of exceptions may occur as a result of the attempted execution of any defined *Floating-Point Load* and *Store* instruction.

1. Debug (Instruction Address Compare)
2. Instruction TLB Error
3. Instruction Storage Interrupt (all types)
4. LRAT Error for instruction fetch [Categories: E.PT and E.HV.LRAT]
5. Program (Illegal Instruction)
6. Floating-Point Unavailable
7. Program (Unimplemented Operation)
8. Data TLB Error
9. Data Storage (all types)
10. Alignment
11. LRAT Error for data access [Categories: E.PT and E.HV.LRAT]
12. Debug (Data Address Compare, Data Value Compare)
13. Debug (Instruction Complete)

If the instruction is causing both a Debug (Instruction Address Compare) and a Debug (Data Address Compare) or Debug (Data Value Compare), and is not causing any of the exceptions listed in items 2-11, it is permissible for both exceptions to be generated and recorded in the DBSR. A single Debug interrupt will result.

7.9.1.2 Exception Priorities for Other Defined Load and Store Instructions and Defined Cache Management Instructions

The following prioritized list of exceptions may occur as a result of the attempted execution of any other defined *Load* or *Store* instruction, or defined *Cache Management* instruction.

1. Debug (Instruction Address Compare)
2. Instruction TLB Error
3. Instruction Storage Interrupt (all types)
4. LRAT Error for instruction fetch [Categories: E.PT and E.HV.LRAT]
5. Program (Illegal Instruction)

6. Program (Privileged Instruction) (*dcbi* only)
7. Program (Unimplemented Operation)
8. Data TLB Error
9. Data Storage (all types)
10. Alignment
11. LRAT Error for data access [Categories: E.PT and E.HV.LRAT]
12. Debug (Data Address Compare, Data Value Compare)
13. Debug (Instruction Complete)

If the instruction is causing both a Debug (Instruction Address Compare) and a Debug (Data Address Compare) or Debug (Data Value Compare), and is not causing any of the exceptions listed in items 2-11, it is permissible for both exceptions to be generated and recorded in the DBSR. A single Debug interrupt will result.

7.9.1.3 Exception Priorities for Other Defined Floating-Point Instructions

The following prioritized list of exceptions may occur as a result of the attempted execution of any defined floating-point instruction other than a load or store.

1. Debug (Instruction Address Compare)
2. Instruction TLB Error
3. Instruction Storage Interrupt (all types)
4. LRAT Error [Categories: E.PT and E.HV.LRAT]
5. Program (Illegal Instruction)
6. Floating-Point Unavailable
7. Program (Unimplemented Operation)
8. Program (Floating-point Enabled)
9. Debug (Instruction Complete)

7.9.1.4 Exception Priorities for Defined Privileged Instructions

The following prioritized list of exceptions may occur as a result of the attempted execution of any defined privileged instruction, except *dcbi*, *rfi*, and *rftci* instructions.

1. Debug (Instruction Address Compare)
2. Instruction TLB Error
3. Instruction Storage Interrupt (all types)
4. LRAT Error [Categories: E.PT and E.HV.LRAT] (for hardware tablewalk)
5. Program (Illegal Instruction, except for *tlbwe* with invalid MAS settings, see 9)
6. Program (Privileged Instruction)
7. Program (Unimplemented Operation)
8. Embedded Hypervisor Privilege [Category: E.HV]
9. Program (Illegal Instruction, special case for *tlbwe* with invalid MAS settings)
10. LRAT Error [Category: E.HV.LRAT] (for *tlbwe*)
11. Debug (Instruction Complete)

For *mtmsr*, *mtspr* (DBCR0, DBCR1, DBCR2), *mtspr* (TCR), and *mtspr* (TSR), if they are not causing Debug (Instruction Address Compare) nor Program (Privileged

Instruction) exceptions, it is possible that they are simultaneously enabling (via mask bits) multiple existing exceptions (and at the same time possibly causing a Debug (Instruction Complete) exception). When this occurs, the interrupts will be handled in the order defined by Section 7.8.2 on page 1058.

7.9.1.5 Exception Priorities for Defined Trap Instructions

The following prioritized list of exceptions may occur as a result of the attempted execution of a defined *Trap* instruction.

1. Debug (Instruction Address Compare)
2. Instruction TLB Error
3. Instruction Storage Interrupt (all types)
4. LRAT Error [Categories: E.PT and E.HV.LRAT]
5. Program (Illegal Instruction)
6. Program (Unimplemented Operation)
7. Debug (Trap)
8. Program (Trap)
9. Debug (Instruction Complete)

If the instruction is causing both a Debug (Instruction Address Compare) and a Debug (Trap), and is not causing any of the exceptions listed in items 2-6, it is permissible for both exceptions to be generated and recorded in the DBSR. A single Debug interrupt will result.

7.9.1.6 Exception Priorities for Defined System Call Instruction

The following prioritized list of exceptions may occur as a result of the attempted execution of a defined *System Call* instruction.

1. Debug (Instruction Address Compare)
2. Instruction TLB Error
3. Instruction Storage Interrupt (all types)
4. LRAT Error [Categories: E.PT and E.HV.LRAT]
5. Program (Illegal Instruction)
6. Program (Unimplemented Operation)
7. System Call
8. Embedded Hypervisor System Call [Category: E.HV]
9. Debug (Instruction Complete)

7.9.1.7 Exception Priorities for Defined Branch Instructions

The following prioritized list of exceptions may occur as a result of the attempted execution of any defined branch instruction.

1. Debug (Instruction Address Compare)
2. Instruction TLB Error
3. Instruction Storage Interrupt (all types)
4. LRAT Error [Categories: E.PT and E.HV.LRAT]
5. Program (Illegal Instruction)

6. Program (Unimplemented Operation)
7. Debug (Branch Taken)
8. Debug (Instruction Complete)

If the instruction is causing both a Debug (Instruction Address Compare) and a Debug (Branch Taken), and is not causing any of the exceptions listed in items 2-6, it is permissible for both exceptions to be generated and recorded in the DBSR. A single Debug interrupt will result.

7.9.1.8 Exception Priorities for Defined Return From Interrupt Instructions

The following prioritized list of exceptions may occur as a result of the attempted execution of an *rfi*, *rfti*, *rfmci*, *rfdi* [Category: Embedded.Enhanced Debug], *rftgi* [Category: Embedded.Hypervisor] instruction.

1. Debug (Instruction Address Compare)
2. Instruction TLB Error
3. Instruction Storage Interrupt (all types)
4. LRAT Error [Categories: E.PT and E.HV.LRAT]
5. Program (Illegal Instruction)
6. Program (Privileged Instruction)
7. Program (Unimplemented Operation)
8. Debug (Return From Interrupt)
9. Debug (Instruction Complete)

If the *rfti* or *rfti*, *rfmci*, or *rfdi* [Category: Embedded.Enhanced Debug] or *rftgi* [Category: Embedded.Hypervisor] instruction is causing both a Debug (Instruction Address Compare) and a Debug (Return From Interrupt), and is not causing any of the exceptions listed in items 2-6, it is permissible for both exceptions to be generated and recorded in the DBSR. A single Debug interrupt will result.

7.9.1.9 Exception Priorities for Other Defined Instructions

The following prioritized list of exceptions may occur as a result of the attempted execution of all other instructions not listed above.

1. Debug (Instruction Address Compare)
2. Instruction TLB Error
3. Instruction Storage Interrupt (all types)
4. LRAT Error instruction fetch [Categories: E.PT and E.HV.LRAT]
5. Program (Illegal Instruction)
6. Program (Unimplemented Operation)
7. Embedded Hypervisor Privilege <E.HV>
8. LRAT Error for data access for *tlbwe* [Category: E.HV.LRAT]
9. Debug (Instruction Complete)

7.9.2 Exception Priorities for Reserved Instructions

The following prioritized list of exceptions may occur as a result of the attempted execution of any reserved instruction.

1. Debug (Instruction Address Compare)
2. Instruction TLB Error
3. Instruction Storage Interrupt (all types)
4. Program (Illegal Instruction)

Chapter 8. Reset and Initialization

8.1 Background	1063	8.4 Software Initialization Requirements	1065
8.2 Reset Mechanisms	1063		
8.3 Thread State after Reset	1063		

8.1 Background

This chapter describes the requirements for thread reset. This includes both the means of causing reset, and the specific initialization that is required to be performed automatically by the hardware. This chapter also provides an overview of the operations that should be performed by initialization software.

In general, the specific actions taken by a thread upon reset are implementation-dependent. Also, it is the responsibility of system initialization software to initialize the majority of thread and system resources after reset. Implementations are required to provide a minimum thread initialization such that this system software may be fetched and executed, thereby accomplishing the rest of system initialization.

8.2 Reset Mechanisms

This specification defines two mechanisms for internally invoking a thread reset operation using either the Watchdog Timer (see Section 9.7 on page 1073) or the Debug facilities using `DBCRO_RST` (see Section 10.5.1.1 on page 1085). In addition, implementations will typically provide additional means for invoking a reset operation, using an external mechanism such as a signal pin, which when activated, causes the thread to be reset.

8.3 Thread State after Reset

The initial thread state is controlled by the register contents after reset. In general, the contents of most registers are undefined after reset.

The hardware is only guaranteed to initialize those registers (or specific bits in registers) which must be initialized in order for software to be able to reliably perform the rest of system initialization.

The Thread Enable Register, Machine State Register, Processor Version Register, and a TLB entry are updated as follows.

Thread Enable Register [Category: Embedded Multi-Threading]

The TEN is set to the value `0x0000_0000_0000_0001`, indicating that only thread 0 is enabled.

Machine State Register

The state of the MSR for all threads is as shown in Figure 61.

Bit	Setting	Comments
CM	0	Computation Mode (set to 32-bit mode)
GS	0	Hypervisor state <E.HV>
UCLE	0	User Cache Locking Enable
SPV	0	SPE/Embedded Floating-Point/Vector Unavailable
CE	0	Critical Input interrupts disabled
DE	0	Debug interrupts disabled
EE	0	External Input interrupts disabled
PR	0	Supervisor mode
FP	0	FP unavailable
ME	0	Machine Check interrupts disabled
FE0	0	FP exception type Program interrupts disabled
FE1	0	FP exception type Program interrupts disabled
IS	0	Instruction Address Space 0
DS	0	Data Address Space 0
PMM	0	Performance Monitor Mark

Figure 61. Machine State Register Initial Values

Logical Partition Identification Register [Category Embedded.Hypervisor]

The Logical Partition Identification Register (LPIDR) is set to 0.

Processor Version Register

Implementation-Dependent. (This register is read-only, and contains a value which identifies the specific implementation)

TLB entry

A TLB entry (which entry is implementation-dependent) is initialized in an implementation-dependent manner that maps the last page in the implemented effective storage address space, with the following field settings:

Field	Setting	Comments
V	1	valid
EPN	see below	Represents the last page in effective address space
RPN	see below	Represents the last page in physical address space
TS	0	translation address space 0
IND <E.PT>	0	direct entry
TLPID <E.HV>	0	translation logical partition ID
TGS <E.HV>	0	translation hypervisor state
SIZE	?	smallest page size supported
W	?	implementation-dependent value
I	?	implementation-dependent value
M	?	implementation-dependent value
G	?	implementation-dependent value
E	?	implementation-dependent value
U0	?	implementation-dependent value
U1	?	implementation-dependent value
U2	?	implementation-dependent value
U3	?	implementation-dependent value
TID	?	implementation-dependent value, but page must be accessible
UX	?	implementation-dependent value
UR	?	implementation-dependent value
UW	?	implementation-dependent value
SX	1	page is execute accessible in supervisor mode
SR	1	page is read accessible in supervisor mode
SW	1	page is write accessible in supervisor mode
VLE	?	implementation-dependent value
ACM	?	implementation-dependent value
IPROT	?	implementation-dependent value
VF <E.HV>	0	no virtualization fault

Figure 62. TLB Initial Values

The initial settings of EPN and RPN are dependent upon the number of bits implemented in the EPN and RPN fields and the minimum page size supported by the implementation. For example, an implementation that supports 64KB pages as the smallest size and 32 bits of effective address would implement a 16 bit EPN and set the initial value of the EPN field of the TLB boot entry to $2^{16}-1$ (0xFFFF) while an implementation that supports 4K pages as the smallest size and 32 bits of effective address would implement a 20 bit EPN and

set the initial value of the boot entry to $2^{20}-1$ (0xFFFFF).

Instruction execution begins at the last word address of the page mapped by the boot TLB entry. Note that this address is different from the System Reset interrupt vector specified in Book III-S.

An implementation may provide additional methods for initializing the TLB entry used for initial boot by providing an implementation-dependent RPN, or initializing other TLB entries.

If Category: Embedded Multi-threading.Thread Management is not supported, instruction execution for other threads begins at the last word address of the effective address space; otherwise execution begins at the address specified by the NIA register corresponding to the thread.

8.4 Software Initialization Requirements

When reset occurs, the thread is initialized to a minimum configuration to start executing initialization code. Initialization code is necessary to complete the thread and system configuration. The initialization code described in this section is the minimum recommended for configuring the thread to run application code.

Initialization code should configure the following resources:

- Invalidate the instruction cache and data cache (implementation-dependent).
- Initialize system memory as required by the operating system or application code.
- Initialize the Interrupt Vector Prefix Register and Interrupt Vector Offset Register.
- Initialize other registers as needed by the system.
- Initialize off-chip system facilities.
- Dispatch the operating system or application code.

Chapter 9. Timer Facilities

9.1 Overview	1067	9.4 Decrementer Auto-Reload Register	1070
9.2 Time Base (TB)	1067	9.5 Timer Control Register	1070
9.2.1 Writing the Time Base	1068	9.5.1 Timer Status Register	1072
9.3 Decrementer	1069	9.6 Fixed-Interval Timer	1073
9.3.1 Writing and Reading the Decrementer	1069	9.7 Watchdog Timer	1073
9.3.2 Decrementer Events	1069	9.8 Freezing the Timer Facilities	1075

9.1 Overview

The Time Base, Decrementer, Fixed-interval Timer, and Watchdog Timer provide timing functions for the system. The remainder of this section describes these registers and related facilities.

9.2 Time Base (TB)

The Time Base (TB) is a 64-bit register (see Figure 63) containing a 64-bit unsigned integer that is incremented periodically. Each increment adds 1 to the low-order bit (bit 63). The frequency at which the integer is updated is implementation-dependent.

Field	Description
TBU	Upper 32 bits of Time Base
TBL	Lower 32 bits of Time Base

Figure 63. Time Base

The Time Base bits 0:59 increment until their value becomes 0xFFFF_FFFF_FFFF_FFFF ($2^{59} - 1$), at the next increment their value becomes 0x000_0000_0000_0000. There is no interrupt or other indication when this occurs.

Time base bits 60:63 may increment at a variable rate. When the value of bit 59 changes, bits 60:63 are set to zero; if bits 60:63 increment to 0xF before the value of bit 59 changes, they remain at 0xF until the value of bit 59 changes.

The period of the Time Base depends on the driving frequency. As an order of magnitude example, suppose that the CPU clock is 1 GHz and that the Time Base is driven by this frequency divided by 32. Then the period of the Time Base would be

$$T_{TB} = \frac{2^{64} \times 32}{1 \text{ GHz}} = 5.90 \times 10^{11} \text{ seconds}$$

which is approximately 18,700 years.

The Time Base is implemented such that:

1. Loading a GPR from the Time Base has no effect on the accuracy of the Time Base.
2. Copying the contents of a GPR to the Time Base replaces the contents of the Time Base with the contents of the GPR.

The Power ISA does not specify a relationship between the frequency at which the Time Base is updated and other frequencies, such as the CPU clock or bus clock in a Power ISA system. The Time Base update frequency is not required to be constant. What *is* required, so that system software can keep time of day and operate interval timers, is one of the following.

- The system provides an (implementation-dependent) interrupt to software whenever the update frequency of the Time Base bits 0:59 changes, and a means to determine what the current update frequency is.
- The update frequency of the Time Base bits 0:59 is under the control of the system software.

Implementations must provide a means for either preventing the Time Base from incrementing or preventing it from being read in user mode ($MSR_{PR}=1$). If the means is under software control, it must be privileged.

There must be a method for getting all Time Bases in the system to start incrementing with values that are identical or almost identical.

Programming Note

If software initializes the Time Base on power-on to some reasonable value and the update frequency of the Time Base is constant, the Time Base can be used as a source of values that increase at a constant rate, such as for time stamps in trace entries.

Even if the update frequency is not constant, values read from the Time Base are monotonically increasing (except when the Time Base wraps from $2^{64}-1$ to 0). If a trace entry is recorded each time the update frequency changes, the sequence of Time Base values can be post-processed to become actual time values.

Successive readings of the Time Base may return identical values.

See the description of the Time Base in Book II, for ways to compute time of day in POSIX format from the Time Base.

9.2.1 Writing the Time Base

Writing the Time Base is hypervisor privileged. Reading the Time Base is not privileged, it is discussed in Book II.

It is not possible to write the entire 64-bit Time Base using a single instruction. The *mttbl* and *mttbu* extended mnemonics write the lower and upper halves of the Time Base (TBL and TBU), respectively, preserving the other half. These are extended mnemonics for the *mtspr* instruction; see Appendix B, “Assembler Extended Mnemonics” on page 1109.

The Time Base can be written by a sequence such as:

```
lwz    Rx,upper # load 64-bit value for
lwz    Ry,lower # TB into Rx and Ry
li     Rz,0
mttbl  Rz      # set TBL to 0
mttbu  Rx      # set TBU
mttbl  Ry      # set TBL
```

Provided that no interrupts occur while the last three instructions are being executed, loading 0 into TBL prevents the possibility of a carry from TBL to TBU while the Time Base is being initialized.

Programming Note

The instructions for writing the Time Base are mode-independent. Thus code written to set the Time Base will work correctly in either 64-bit or 32-bit mode.

9.3 Decrementer

The Decrementer (DEC) is a 32-bit decrementing counter that provides a mechanism for causing a Decrementer interrupt after a programmable delay. The contents of the Decrementer are treated as a signed integer.

Figure 64. Decrementer

Decrementer bits 32:59 count down until their value becomes 0x000_0000, at the next increment their value becomes 0xFFFF_FFFF. Decrementer bits 60:63 may decrement at a variable rate. When the value of bit 59 changes, bits 60:63 are set to 0xF; if bits 60:63 decrement to 0x0 before the value of bit 59 changes, they remain at 0x0 until the value of bit 59 changes.

The Decrementer is driven by the same frequency as the Time Base. The period of the Decrementer will depend on the driving frequency, but if the same values are used as given above for the Time Base (see Section 9.2), and if the Time Base update frequency is constant, the period would be

$$T_{\text{DEC}} = \frac{2^{32} \times 32}{1 \text{ GHz}} = 137 \text{ seconds.}$$

The Decrementer counts down.

The operation of the Decrementer satisfies the following constraints.

1. The operation of the Time Base and the Decrementer is coherent, i.e., the counters are driven by the same fundamental time base.
2. Loading a GPR from the Decrementer has no effect on the accuracy of the Time Base.
3. Copying the contents of a GPR to the Decrementer replaces the contents of the Decrementer with the contents of the GPR.

Programming Note

In systems that change the Time Base update frequency for purposes such as power management, the Decrementer input frequency will also change. Software must be aware of this in order to set interval timers.

If Decrementer bits 60:63 are used as part of a random number generator, software must account for the fact that these bits are set to 0xF only when bit 59 changes state regardless of whether or not they decremented to 0x0 since they were previously set to 0xF.

9.3.1 Writing and Reading the Decrementer

The contents of the Decrementer can be read or written using the *mf spr* and *mt spr* instructions, both of which are hypervisor privileged. Using an extended mnemonic (see Appendix B, “Assembler Extended Mnemonics” on page 1109), the Decrementer can be written from GPR Rx using:

```
mtdec Rx
```

The Decrementer can be read into GPR Rx using:

```
mfdec Rx
```

Copying the Decrementer to a GPR has no effect on the Decrementer contents or on the interrupt mechanism.

9.3.2 Decrementer Events

A Decrementer event occurs when a decrement occurs on a Decrementer value of 0x0000_0001.

Upon the occurrence of a Decrementer event, the Decrementer may be reloaded from a 32-bit Decrementer Auto-Reload Register (DECAR). See Section 9.4. Upon the occurrence of a Decrementer event, the Decrementer has the following basic modes of operation.

Decrement to one and stop on zero

If $\text{TCR}_{\text{ARE}}=0$, TSR_{DIS} is set to 1, the value 0x0000_0000 is then placed into the DEC, and the Decrementer stops decrementing.

A Decrementer interrupt occurs when no higher priority interrupt exists, a Decrementer exception exists, and the exception is enabled. If category Embedded.Hypervisor is supported, the interrupt is enabled by $\text{TCR}_{\text{DIE}}=1$ and ($\text{MSR}_{\text{EE}}=1$ or $\text{MSR}_{\text{GS}}=1$). Otherwise, the interrupt is enabled by $\text{TCR}_{\text{DIE}}=1$ and $\text{MSR}_{\text{EE}}=1$. See Section 7.6.12, “Decrementer Interrupt” on page 1043 for details of register behavior caused by the Decrementer interrupt.

Decrement to one and auto-reload

If $\text{TCR}_{\text{ARE}}=1$, TSR_{DIS} is set to 1, the contents of the Decrementer Auto-Reload Register is then placed into the DEC, and the Decrementer continues decrementing from the reloaded value.

A Decrementer interrupt occurs when no higher priority interrupt exists, a Decrementer exception exists, and the exception is enabled. If category Embedded.Hypervisor is supported, the interrupt is enabled by $\text{TCR}_{\text{DIE}}=1$ and ($\text{MSR}_{\text{EE}}=1$ or $\text{MSR}_{\text{GS}}=1$). Otherwise, the interrupt is enabled by $\text{TCR}_{\text{DIE}}=1$ and $\text{MSR}_{\text{EE}}=1$. See Section 7.6.12,

“Decrementer Interrupt” on page 1043 for details of register behavior caused by the Decrementer interrupt.

Forcing the Decrementer to 0 using the *mtspr* instruction will not cause a Decrementer exception; however, decrementing which was in progress at the instant of the *mtspr* may cause the exception. To eliminate the Decrementer as a source of exceptions, set TCR_{DIE} to 0 (clear the Decrementer Interrupt Enable bit).

If it is desired to eliminate all Decrementer activity, the procedure is as follows:

1. Write 0 to TCR_{DIE} . This will prevent Decrementer activity from causing exceptions.
2. Write 0 to TCR_{ARE} to disable the Decrementer auto-reload.
3. Write 0 to Decrementer. This will halt Decrementer decrementing. While this action will not cause a Decrementer exception to be set in TSR_{DIS} , a near simultaneous decrement may have done so.
4. Write 1 to TSR_{DIS} . This action will clear TSR_{DIS} to 0 (see Section 9.5.1 on page 1072). This will clear any Decrementer exception which may be pending. Because the Decrementer is frozen at zero, no further Decrementer events are possible.

If the auto-reload feature is disabled ($TCR_{ARE}=0$), then once the Decrementer decrements to zero, it will stay there until software reloads it using the *mtspr* instruction.

On reset, TCR_{ARE} is set to 0. This disables the auto-reload feature.

9.4 Decrementer Auto-Reload Register

The Decrementer Auto-Reload Register is a 32-bit register as shown below.

Figure 65. Decrementer

Bits of the decrementer auto-reload register are numbered 32 (most-significant bit) to 63 (least-significant bit). The Decrementer Auto-Reload Register is provided to support the auto-reload feature of the Decrementer. See Section 9.3.2

The contents of the Decrementer Auto-Reload Register cannot be read. The contents of bits 32:63 of register RS can be written to the Decrementer Auto-Reload Register using the *mtspr* instruction.

This register is hypervisor privileged.

9.5 Timer Control Register

The Timer Control Register (TCR) is a 32-bit register. Timer Control Register bits are numbered 32 (most-significant bit) to 63 (least-significant bit). The Timer Control Register controls Decrementer (see Section 9.3), Fixed-Interval Timer (see Section 9.6), and Watchdog Timer (see Section 9.7) options.

The relationship of the Timer facilities to the TCR and TB is shown in the figure below.

This register is hypervisor privileged.

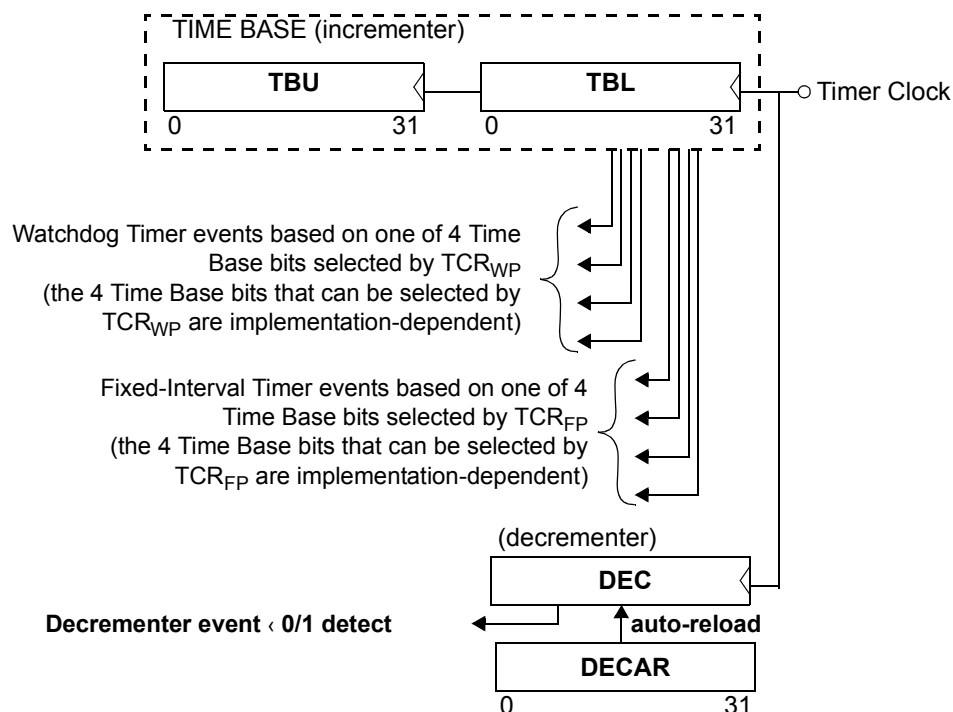

Figure 66. Relationships of the Timer Facilities

The contents of the Timer Control Register can be read using the *mfspr* instruction. The contents of bits 32:63 of register RS can be written to the Timer Control Register using the *mtspr* instruction.

The contents of the TCR are defined below:

Bit(s) Description

32:33 **Watchdog Timer Period** (WP) (see Section 9.7 on page 1073)

Specifies one of 4 bit locations of the Time Base used to signal a Watchdog Timer exception on a transition from 0 to 1. The 4 Time Base bits that can be specified to serve as the Watchdog Timer period are implementation-dependent.

34:35 **Watchdog Timer Reset Control** (WRC) (see Section 9.7 on page 1073)

00 No Watchdog Timer reset will occur

TCR_{WRC} resets to 0b00. This field may be set by software, but cannot be cleared by software (except by a software-induced reset)

01-11

Force thread to be reset on second timeout of Watchdog Timer. The exact func-

tion of any of these settings is implementation-dependent.

The Watchdog Timer Reset Control field is cleared to zero by reset. These bits are set only by software. Once a 1 has been written to one of these bits, that bit remains a 1 until a reset occurs. This is to prevent errant code from disabling the Watchdog reset function.

36 **Watchdog Timer Interrupt Enable** (WIE) (see Section 9.7 on page 1073)

0 Disable Watchdog Timer interrupt
1 Enable Watchdog Timer interrupt

37 **Decrementer Interrupt Enable** (DIE) (see Section 9.3 on page 1069)

0 Disable Decrementer interrupt
1 Enable Decrementer interrupt

38:39 **Fixed-Interval Timer Period** (FP) (see Section 9.6 on page 1073)

Specifies one of 4 bit locations of the Time Base used to signal a Fixed-Interval Timer exception on a transition from 0 to 1. The 4 Time Base bits that can be specified to serve as the Fixed-Interval Timer period are implementation-dependent.

40 **Fixed-Interval Timer Interrupt Enable** (FIE) (see Section 9.6 on page 1073)

	0	Disable Fixed-Interval Timer interrupt
	1	Enable Fixed-Interval Timer interrupt
41	Auto-Reload Enable (ARE)	
	0	Disable auto-reload of the Decrementer
		Decrementer exception is presented (i.e. TSR_{DIS} is set to 1) when the Decrementer is decremented from a value of 0x0000_0001. The next value placed in the Decrementer is the value 0x0000_0000. If category Embedded.Hypervisor is supported, when ($MSR_{EE}=1$ or $MSR_{GS}=1$), $TCRD_{IE}=1$, and $TSR_{DIS}=1$, a Decrementer interrupt is taken. If category Embedded.Hypervisor is not supported, when $MSR_{EE}=1$, $TCRD_{IE}=1$, and $TSR_{DIS}=1$, a Decrementer interrupt is taken. Software must reset TSR_{DIS} .
	1	Enable auto-reload of the Decrementer
		Decrementer exception is presented (i.e. TSR_{DIS} is set to 1) when the Decrementer is decremented from a value of 0x0000_0001. The contents of the Decrementer Auto-Reload Register is placed in the Decrementer. If category Embedded.Hypervisor is supported, when ($MSR_{EE}=1$ or $MSR_{GS}=1$), $TCRD_{IE}=1$, and $TSR_{DIS}=1$, a Decrementer interrupt is taken. If category Embedded.Hypervisor is not supported, when $MSR_{EE}=1$, $TCRD_{IE}=1$, and $TSR_{DIS}=1$, a Decrementer interrupt is taken. Software must reset TSR_{DIS} .
42	Implementation-dependent	
43:63	Reserved	

9.5.1 Timer Status Register

The Timer Status Register (TSR) is a 32-bit register. Timer Status Register bits are numbered 32 (most-significant bit) to 63 (least-significant bit). The Timer Status Register contains status on timer events and the most recent Watchdog Timer-initiated thread reset.

The Timer Status Register is set via hardware, and read and cleared via software. The contents of the Timer Status Register can be read using the *mfspir* instruction. Bits in the Timer Status Register can be cleared using the *mtspir* instruction. Clearing is done by writing bits 32:63 of a General Purpose Register to the Timer Status Register with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write-data to the Timer Status Register is not direct data, but a mask. A 1 causes the bit to be cleared, and a 0 has no effect.

The contents of the TSR are defined below:

Bit(s)	Description
32	Enable Next Watchdog Timer (ENW) (see Section 9.7 on page 1073)
	0 Action on next Watchdog Timer time-out is to set $TSRENW$
	1 Action on next Watchdog Timer time-out is governed by $TSRWIS$
33	Watchdog Timer Interrupt Status (WIS) (see Section 9.7 on page 1073)
	0 A Watchdog Timer event has not occurred.
	1 A Watchdog Timer event has occurred. If category Embedded.Hypervisor is supported, when ($MSR_{CE}=1$ or $MSR_{GS}=1$) and $TCR_{WIE}=1$, a Watchdog Timer interrupt is taken. If category Embedded.Hypervisor is not supported, when $MSR_{CE}=1$ and $TCR_{WIE}=1$, a Watchdog Timer interrupt is taken.
34:35	Watchdog Timer Reset Status (WRS) (see Section 9.7 on page 1073)
	These two bits are set to one of three values when a reset is caused by the Watchdog Timer. These bits are undefined at power-up.
	00 No Watchdog Timer reset has occurred.
	01 Implementation-dependent reset information.
	10 Implementation-dependent reset information.
	11 Implementation-dependent reset information.
36	Decrementer Interrupt Status (DIS) (see Section 9.3.2 on page 1069)
	0 A Decrementer event has not occurred.
	1 A Decrementer event has occurred. When $MSR_{EE}=1$ and $TCR_{DIE}=1$, a Decrementer interrupt is taken.
37	Fixed-Interval Timer Interrupt Status (FIS) (see Section 9.6 on page 1073)
	0 A Fixed-Interval Timer event has not occurred.
	1 A Fixed-Interval Timer event has occurred. If category Embedded.Hypervisor is supported, when ($MSR_{EE}=1$ or $MSR_{GS}=1$) and $TCR_{FIE}=1$, a Fixed-Interval Timer interrupt is taken. If category Embedded.Hypervisor is not supported, when $MSR_{EE}=1$ and $TCR_{FIE}=1$, a Fixed-Interval Timer interrupt is taken.
38:63	Reserved
	This register is hypervisor privileged.

9.6 Fixed-Interval Timer

The Fixed-Interval Timer (FIT) is a mechanism for providing timer interrupts with a repeatable period, to facil-

itate system maintenance. It is similar in function to an auto-reload Decrementer, except that there are fewer selections of interrupt period available. The Fixed-Interval Timer exception occurs on 0 to 1 transitions of a selected bit from the Time Base (see Section 9.5).

The Fixed-Interval Timer exception is logged by TSR_{FIS} . A Fixed-Interval Timer interrupt occurs when no higher priority interrupt exists (see Section 7.9 on page 1059), a Fixed-Interval Timer exception exists ($TSR_{FIS}=1$), and the exception is enabled. If category Embedded.Hypervisor is supported, the interrupt is enabled by $TCR_{FIE}=1$ and ($MSR_{EE} = 1$ or $MSR_{GS}=1$). Otherwise, the interrupt is enabled by $TCR_{FIE}=1$ and $MSR_{EE}=1$. See Section 7.6.13 on page 1043 for details of register behavior caused by the Fixed-Interval Timer interrupt.

Note that a Fixed-Interval Timer exception will also occur if the selected Time Base bit transitions from 0 to 1 due to an *mtspr* instruction that writes a 1 to the bit when its previous value was 0.

9.7 Watchdog Timer

The Watchdog Timer is a facility intended to aid system recovery from faulty software or hardware. Watchdog time-outs occur on 0 to 1 transitions of selected bits from the Time Base (Section 9.5).

When a Watchdog Timer time-out occurs while Watchdog Timer Interrupt Status is clear ($TSR_{WIS} = 0$) and the next Watchdog Time-out is enabled ($TSR_{ENW} = 1$), a Watchdog Timer exception is generated and logged by setting TSR_{WIS} to 1. This is referred to as a Watchdog Timer First Time Out. A Watchdog Timer interrupt occurs when no higher priority interrupt exists (see Section 7.9 on page 1059), a Watchdog Timer exception exists ($TSR_{WIS}=1$), and the exception is enabled. If category Embedded.Hypervisor is supported, the interrupt is enabled by $TCR_{WIE}=1$ and ($MSR_{CE} = 1$ or $MSR_{GS}=1$). Otherwise, the interrupt is enabled by $TCR_{WIE}=1$ and $MSR_{CE}=1$. See Section 7.6.14 on page 1044 for details of register behavior caused by the Watchdog Timer Interrupt. The purpose of the Watchdog Timer First time-out is to give an indication that there may be problem and give the system a chance to perform corrective action or capture a failure before a reset occurs from the Watchdog Timer Second time-out as explained further below.

Note that a Watchdog Timer exception will also occur if the selected Time Base bit transitions from 0 to 1 due to an *mtspr* instruction that writes a 1 to the bit when its previous value was 0.

When a Watchdog Timer time-out occurs while $TSR_{WIS} = 1$ and $TSR_{ENW} = 1$, a thread reset occurs if it is enabled by a non-zero value of the Watchdog Reset Control field in the Timer Control Register (TCR_{WRC}). This is referred to as a Watchdog Timer Second Time

Out. The assumption is that TSR_{WIS} was not cleared because the thread was unable to execute the Watchdog Timer interrupt handler, leaving reset as the only available means to restart the system. Note that once TCR_{WRC} has been set to a non-zero value, it cannot be reset by software; this feature prevents errant software from disabling the Watchdog Timer reset capability.

A more complete view of Watchdog Timer behavior is afforded by Figure 67 and Figure 68, which describe the Watchdog Timer state machine and Watchdog Timer controls. The numbers in parentheses in the figure refer to the discussion of modes of operation which follow the table.

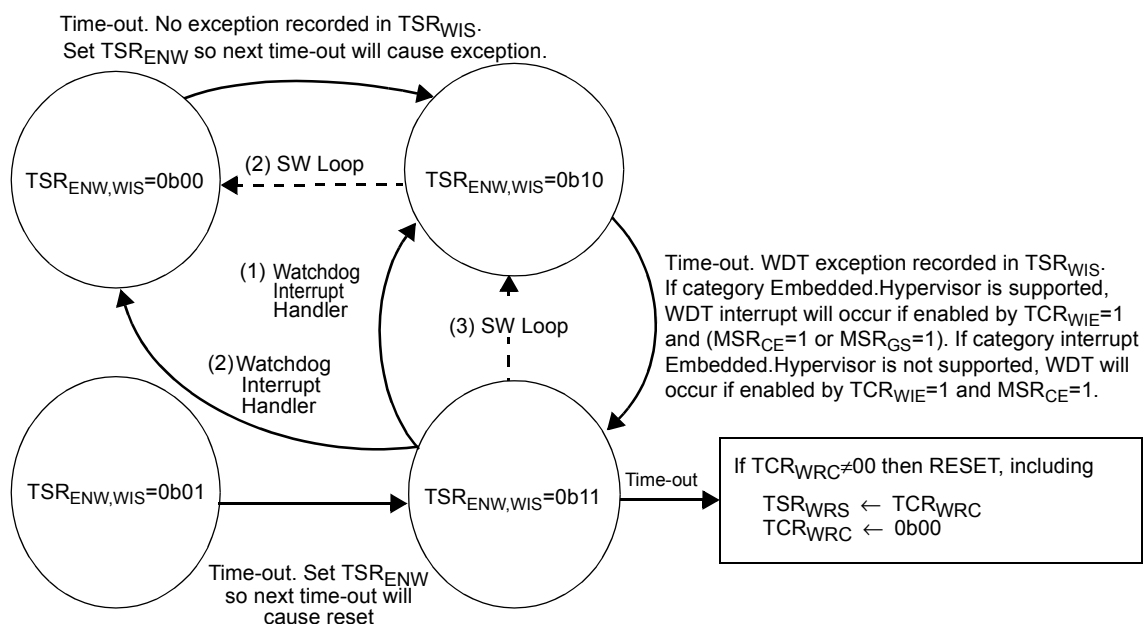

Figure 67. Watchdog State Machine

Enable Next WDT (TSR_{ENW})	WDT Status (TSR_{WIS})	Action when timer interval expires
0	0	Set Enable Next Watchdog Timer ($TSR_{ENW}=1$).
0	1	Set Enable Next Watchdog Timer ($TSR_{ENW}=1$).
1	0	Set Watchdog Timer interrupt status bit ($TSR_{WIS}=1$). If category Embedded.Hypervisor is supported and Watchdog Timer interrupt is enabled ($TCR_{WIE}=1$ and $(MSR_{CE}=1$ or $MSR_{GS}=1)$), then interrupt. If category Embedded.Hypervisor is not supported and Watchdog Timer interrupt is enabled ($TCR_{WIE}=1$ and $MSR_{CE}=1$), then interrupt.
1	1	Cause Watchdog Timer reset action specified by TCR_{WRC} . Reset will copy pre-reset TCR_{WRC} into TSR_{WRS} , then clear TCR_{WRC} .

Figure 68. Watchdog Timer Controls

The controls described in the above table imply three different modes of operation that a programmer might select for the Watchdog Timer. Each of these modes assumes that TCR_{WRC} has been set to allow thread reset by the Watchdog facility:

1. Always take the Watchdog Timer interrupt when pending, and never attempt to prevent its occurrence. In this mode, the Watchdog Timer interrupt caused by a first time-out is used to clear TSR_{WIS} so a second time-out never occurs. TSR_{ENW} is not cleared, thereby allowing the next time-out to cause another interrupt.

2. Always take the Watchdog Timer interrupt when pending, but avoid when possible. In this mode a recurring code loop of reliable duration (or perhaps a periodic interrupt handler such as the Fixed-Interval Timer interrupt handler) is used to repeatedly clear TSR_{ENW} such that a first time-out exception is avoided, and thus no Watchdog Timer interrupt occurs. Once TSR_{ENW} has been cleared, software has between one and two full Watchdog periods before a Watchdog exception will be posted in TSR_{WIS} . If this occurs before the software is able to clear TSR_{ENW} again, a Watchdog

Timer interrupt will occur. In this case, the Watchdog Timer interrupt handler will then clear both TSR_{ENW} and TSR_{WIS} , in order to (hopefully) avoid the next Watchdog Timer interrupt.

3. Never take the Watchdog Timer interrupt. In this mode, Watchdog Timer interrupts are disabled (via $TCR_{WIE}=0$), and the system depends upon a recurring code loop of reliable duration (or perhaps a periodic interrupt handler such as the Fixed-Interval Timer interrupt handler) to repeatedly clear TSR_{WIS} such that a second time-out is avoided, and thus no reset occurs. TSR_{ENW} is not cleared, thereby allowing the next time-out to set TSR_{WIS} again. The recurring code loop must have a period which is less than one Watchdog Timer period in order to guarantee that a Watchdog Timer reset will not occur.

9.8 Freezing the Timer Facilities

The debug mechanism provides a means of temporarily freezing the timers upon a debug event. Specifically, the Time Base and Decrementer can be frozen and prevented from incrementing/decrementing, respectively, whenever a debug event is set in the Debug Status Register. Note that this also freezes the FIT and Watchdog timer. This allows a debugger to simulate the appearance of 'real time', even though the application has been temporarily 'halted' to service the debug event. See the description of bit 63 of the Debug Control Register 0 (Freeze Timers on Debug Event or $DBCRO_{FT}$) in Section 10.5.1.1 on page 1085.

10.1 Overview

Debug facilities are provided to enable hardware and software debug functions, such as instruction and data breakpoints and program single stepping. The debug facilities consist of a set of Debug Control Registers (DBCR0, DBCR1, and DBCR2) (see Section 10.5.1 on page 1085), a set of Address and Data Value Compare Registers (IAC1, IAC2, IAC3, IAC4, DAC1, DAC2, DVC1, and DVC2), (see Section 10.4.3, Section 10.4.4, and Section 10.4.5), a Debug Status Register (DBSR) (see Section 10.5.2) for enabling and recording various kinds of debug events, and a special Debug interrupt type built into the interrupt mechanism (see Section 7.6.17). The debug facilities also provide a mechanism for software-controlled thread reset, and for controlling the operation of the timers in a debug environment.

The *mfspr* and *mtspr* instructions (see Section 5.4.1) provide access to the registers of the debug facilities.

In addition to the facilities described here, implementations will typically include debug facilities, modes, and access mechanisms which are implementation-specific. For example, implementations will typically provide access to the debug facilities via a dedicated interface such as the IEEE 1149.1 Test Access Port (JTAG).

10.2 Internal Debug Mode

Debug events include such things as instruction and data breakpoints. These debug events cause status bits to be set in the Debug Status Register. The existence of a set bit in the Debug Status Register is considered a Debug exception. Debug exceptions, if enabled, will cause Debug interrupts.

There are two different mechanisms that control whether Debug interrupts are enabled. The first is the MSR_{DE} bit, and this bit must be set to 1 to enable Debug interrupts. The second mechanism is an enable bit in the Debug Control Register 0 (DBCR0). This bit is the Internal Debug Mode bit ($DBCR0_{IDM}$), and it must also be set to 1 to enable Debug interrupts.

When $DBCR0_{IDM}=1$, the thread is in Internal Debug Mode. In this mode, debug events will (if also enabled by MSR_{DE}) cause Debug interrupts. Software at the Debug interrupt vector location will thus be given control upon the occurrence of a debug event, and can access (via the normal instructions) all architected resources. In this fashion, debug monitor software can control the thread and gather status, and interact with debugging hardware.

When the thread is not in Internal Debug Mode ($DBCR0_{IDM}=0$), debug events may still occur and be recorded in the Debug Status Register. These exceptions may be monitored via software by reading the Debug Status Register (using *mf spr*), or may eventually cause a Debug interrupt if later enabled by setting $DBCR0_{IDM}=1$ (and $MSR_{DE}=1$). Behavior when debug events occur while $DBCR0_{IDM}=0$ is implementation-dependent.

10.3 External Debug Mode [Category: Embedded.Enhanced Debug]

The External Debug Mode is a mode in which external facilities can control execution and access registers and other resources. These facilities are defined as the *external debug* facilities and are not defined here, however some instructions and registers share internal and external debug roles and are briefly described as necessary.

A *dnh* instruction is provided to stop instruction fetching and execution and allow the thread to be managed by an external debug facility. After the *dnh* instruction is executed, instructions are not fetched, interrupts are not taken, and the thread does not execute instructions.

10.4 Debug Events

Debug events are used to cause Debug exceptions to be recorded in the Debug Status Register (see Section 10.5.2). In order for a debug event to be enabled to set a Debug Status Register bit and thereby cause a Debug exception, the specific event type must be enabled by a corresponding bit or bits in the Debug Control Register DBCR0 (see Section 10.5.1.1), DBCR1 (see Section 10.5.1.2), or DBCR2 (see Section 10.5.1.3), in most cases; the Unconditional

Debug Event (UDE) is an exception to this rule. Once a Debug Status Register bit is set, if Debug interrupts are enabled by MSR_{DE} , a Debug interrupt will be generated.

[Category: Embedded.Hypervisor]

To prevent spurious hypervisor debug events from occurring when a guest has been permitted to use the Debug facilities, if the thread is in hypervisor state ($MSR_{GS}=0$) and debug events are disabled for hypervisor ($EPCR_{DUVD}=1$), no debug events are allowed to occur except for the Unconditional Debug Event. It is implementation-dependent whether the Unconditional Debug Event is allowed to occur in hypervisor state when $EPCR_{DUVD}=1$.

Certain debug events are not allowed to occur when $MSR_{DE}=0$. In such situations, no Debug exception occurs and thus no Debug Status Register bit is set. Other debug events may cause Debug exceptions and set Debug Status Register bits regardless of the state of MSR_{DE} . The associated Debug interrupts that result from such Debug exceptions will be delayed until $MSR_{DE}=1$, provided the exceptions have not been cleared from the Debug Status Register in the meantime.

Any time that a Debug Status Register bit is allowed to be set while $MSR_{DE}=0$, a special Debug Status Register bit, Imprecise Debug Event ($DBSR_{IDE}$), will also be set. $DBSR_{IDE}$ indicates that the associated Debug exception bit in the Debug Status Register was set while Debug interrupts were disabled via the $MMSR_{DE}$ bit. Debug interrupt handler software can use this bit to determine whether the address recorded in CSRR0/DSRR0 [Category: Embedded.Enhanced Debug] should be interpreted as the address associated with the instruction causing the Debug exception, or simply the address of the instruction after the one which set the MSR_{DE} bit, thereby enabling the delayed Debug interrupt.

Debug interrupts are ordered with respect to other interrupt types (see Section 7.8 on page 179). Debug exceptions are prioritized with respect to other exceptions (see Section 7.9 on page 183).

There are eight types of debug events defined:

1. Instruction Address Compare debug events
2. Data Address Compare debug events
3. Trap debug events
4. Branch Taken debug events
5. Instruction Complete debug events
6. Interrupt Taken debug events
7. Return debug events
8. Unconditional debug events
9. Critical Interrupt Taken debug events [Category Embedded.Enhanced Debug]
10. Critical Interrupt Return debug events [Category Embedded.Enhanced Debug]

Programming Note

There are two classes of debug exception types:

Type 1: exception before instruction

Type 2: exception after instruction

Almost all debug exceptions fall into the first type. That is, they all take the interrupt upon encountering an instruction having the exception without updating any architectural state (other than DBSR, CSRR0/DSRR0 [Category: Embedded.Enhanced Debug], CSRR1/DSRR1 [Category: Embedded.Enhanced Debug], MSR) for that instruction.

The CSRR0/DSRR0 [Category: Embedded.Enhanced Debug] for this type of exception points to the instruction that encountered the exception. This includes IAC, DAC, branch taken, etc.

The only exception which fall into the second type is the instruction complete debug exception. This exception is taken upon completing and updating one instruction and then pointing CSRR0/DSRR0 [Category: Embedded.Enhanced Debug] to the next instruction to execute.

To make forward progress for any Type 1 debug exception one does the following:

1. Software sets up Type 1 exceptions (e.g. branch taken debug exceptions) and then returns to normal program operation
2. Hardware takes Debug interrupt upon the first branch taken Debug exception, pointing to the branch with CSRR0/DSRR0 [Category: Embedded.Enhanced Debug].
3. Software, in the debug handler, sees the branch taken exception type, does whatever logging/anal-

ysis it wants to, then clears all debug event enables in the DBCR except for the instruction complete debug event enable.

4. Software does an *rfci* or *rfdi* [Category: Embedded.Enhanced Debug].
5. Hardware would execute and complete one instruction (the branch taken in this case), and then take a Debug interrupt with CSRR0/DSRR0 [Category: Embedded.Enhanced Debug] pointing to the target of the branch.
6. Software would see the instruction complete interrupt type. It clears the instruction complete event enable, then enables the branch taken interrupt event again.
7. Software does an *rfci* or *rfdi* [Category: Embedded.Enhanced Debug].
8. Hardware resumes on the target of the taken branch and continues until another taken branch, in which case we end up at step 2 again.

This, at first, seems like a double tax (i.e. 2 debug interrupts for every instance of a Type 1 exception), but there doesn't seem like any other clean way to make forward progress on Type 1 debug exceptions. The only other way to avoid the double tax is to have the debug handler routine actually emulate the instruction pointed to for the Type 1 exceptions, determine the next instruction that would have been executed by the interrupted program flow and load the CSRR0/DSRR0 [Category: Embedded.Enhanced Debug] with that address and do an *rfci/rfdi* [Category: Embedded.Enhanced Debug]; this is probably not faster.

10.4.1 Instruction Address Compare Debug Event

One or more Instruction Address Compare debug events (IAC1, IAC2, IAC3 or IAC4) occur if they are enabled and execution is attempted of an instruction at an address that meets the criteria specified in the DBCR0, DBCR1, IAC1, IAC2, IAC3, and IAC4 Registers.

Instruction Address Compare User/Supervisor Mode

DBCR1_{IAC1US} specifies whether IAC1 debug events can occur in user mode or supervisor mode, or both.

DBCR1_{IAC2US} specifies whether IAC2 debug events can occur in user mode or supervisor mode, or both.

DBCR1_{IAC3US} specifies whether IAC3 debug events can occur in user mode or supervisor mode, or both.

DBCR1_{IAC4US} specifies whether IAC4 debug events can occur in user mode or supervisor mode, or both.

Effective/Real Address Mode

DBCR1_{IAC1ER} specifies whether effective addresses, real addresses, effective addresses and MSR_{IS}=0, or effective addresses and MSR_{IS}=1 are used in determining an address match on IAC1 debug events.

DBCR1_{IAC2ER} specifies whether effective addresses, real addresses, effective addresses and MSR_{IS}=0, or

effective addresses and $MSR_{IS}=1$ are used in determining an address match on IAC2 debug events.

$DBC1_{IAC3ER}$ specifies whether effective addresses, real addresses, effective addresses and $MSR_{IS}=0$, or effective addresses and $MSR_{IS}=1$ are used in determining an address match on IAC3 debug events.

$DBC1_{IAC4ER}$ specifies whether effective addresses, real addresses, effective addresses and $MSR_{IS}=0$, or effective addresses and $MSR_{IS}=1$ are used in determining an address match on IAC4 debug events.

Instruction Address Compare Mode

$DBC1_{IAC12M}$ specifies whether all or some of the bits of the address of the instruction fetch must match the contents of the IAC1 or IAC2, whether the address must be inside a specific range specified by the IAC1 and IAC2 or outside a specific range specified by the IAC1 and IAC2 for an IAC1 or IAC2 debug event to occur.

$DBC1_{IAC34M}$ specifies whether all or some of the bits of the address of the instruction fetch must match the contents of the IAC3 Register or IAC4 Register, whether the address must be inside a specific range specified by the IAC3 Register and IAC4 Register or outside a specific range specified by the IAC3 Register and IAC4 Register for an IAC3 or IAC4 debug event to occur.

There are four instruction address compare modes.

There are four instruction address compare modes.

- *Exact address compare mode*
If the address of the instruction fetch is equal to the value in the enabled IAC Register, an instruction address match occurs. For 64-bit implementations, the addresses are masked to compare only bits 32:63 when the thread is executing in 32-bit mode.
- *Address bit match mode*
For IAC1 and IAC2 debug events, if the address of the instruction fetch access, ANDed with the contents of the IAC2, are equal to the contents of the IAC1, also ANDed with the contents of the IAC2, an instruction address match occurs.

For IAC3 and IAC4 debug events, if the address of the instruction fetch, ANDed with the contents of the IAC4, are equal to the contents of the IAC3, also ANDed with the contents of the IAC4, an instruction address match occurs.

For 64-bit implementations, the addresses are masked to compare only bits 32:63 when the thread is executing in 32-bit mode.
- *Inclusive address range compare mode*
For IAC1 and IAC2 debug events, if the 64-bit

address of the instruction fetch is greater than or equal to the contents of the IAC1 and less than the contents of the IAC2, an instruction address match occurs.

For IAC3 and IAC4 debug events, if the 64-bit address of the instruction fetch is greater than or equal to the contents of the IAC3 and less than the contents of the IAC4, an instruction address match occurs.

- For 64-bit implementations, the addresses are masked to compare only bits 32:63 when the thread is executing in 32-bit mode.

- *Exclusive address range compare mode*

For IAC1 and IAC2 debug events, if the 64-bit address of the instruction fetch is less than the contents of the IAC1 or greater than or equal to the contents of the IAC2, an instruction address match occurs.

For IAC3 and IAC4 debug events, if the 64-bit address of the instruction fetch is less than the contents of the IAC3 or greater than or equal to the contents of the IAC4, an instruction address match occurs.

For 64-bit implementations, the addresses are masked to compare only bits 32:63 when the thread is executing in 32-bit mode.

See the detailed description of DBCR0 (see Section 10.5.1.1, “Debug Control Register 0 (DBCRO)” on page 1085) and DBCR1 (see Section 10.5.1.2, “Debug Control Register 1 (DBC1)” on page 1087) and the modes for detecting IAC1, IAC2, IAC3 and IAC4 debug events. Instruction Address Compare debug events can occur regardless of the setting of MSR_{DE} or $DBC0_{IDM}$.

When an Instruction Address Compare debug event occurs, the corresponding $DBSR_{IAC1}$, $DBSR_{IAC2}$, $DBSR_{IAC3}$, or $DBSR_{IAC4}$ bit or bits are set to record the debug exception. If $MSR_{DE}=0$, $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If $MSR_{DE}=1$ (i.e. Debug interrupts are enabled) at the time of the Instruction Address Compare debug exception, a Debug interrupt will occur immediately (provided there exists no higher priority exception which is enabled to cause an interrupt). The execution of the instruction causing the exception will be suppressed, and CSRR0/DSRR0 [Category: Embedded.Enhanced Debug] will be set to the address of the excepting instruction.

If $MSR_{DE}=0$ (i.e. Debug interrupts are disabled) at the time of the Instruction Address Compare debug exception, a Debug interrupt will not occur, and the instruction will complete execution (provided the instruction is not causing some other exception which will generate an enabled interrupt).

Later, if the debug exception has not been reset by clearing $DBSR_{IAC1}$, $DBSR_{IAC2}$, $DBSR_{IAC3}$, and $DBSR_{IAC4}$, and MSR_{DE} is set to 1, a delayed Debug interrupt will occur. In this case, $CSRR0/DSRR0$ [Category: Embedded.Enhanced Debug] will contain the address of the instruction after the one which enabled the Debug interrupt by setting MSR_{DE} to 1. Software in the Debug interrupt handler can observe $DBSR_{IDE}$ to determine how to interpret the value in $CSRR0/DSRR0$ [Category: Embedded.Enhanced Debug].

10.4.2 Data Address Compare Debug Event

One or more Data Address Compare debug events ($DAC1R$, $DAC1W$, $DAC2R$, $DAC2W$) occur if they are enabled, execution is attempted of a data storage access instruction, and the type, address, and possibly even the data value of the data storage access meet the criteria specified in the Debug Control Register 0, Debug Control Register 2, and the $DAC1$, $DAC2$, $DVC1$, and $DVC2$ Registers.

Data Address Compare Read/Write Enable

$DBCR0_{DAC1}$ specifies whether $DAC1R$ debug events can occur on read-type data storage accesses and whether $DAC1W$ debug events can occur on write-type data storage accesses.

$DBCR0_{DAC2}$ specifies whether $DAC2R$ debug events can occur on read-type data storage accesses and whether $DAC2W$ debug events can occur on write-type data storage accesses.

Indexed-string instructions (*lswx*, *stswx*) for which the XER field specifies zero bytes as the length of the string are treated as no-ops, and are not allowed to cause Data Address Compare debug events.

All *Load* instructions are considered reads with respect to debug events, while all *Store* instructions are considered writes with respect to debug events. In addition, the *Cache Management* instructions, and certain special cases, are handled as follows.

- *dcbt*, *dcbtls*, *dcbtep*, *icbt*, *icbtls*, *icbtep*, *icbi*, *icblc*, *dcblc*, and *icbiep* are all considered reads with respect to debug events. Note that *dcbt*, *dcbtep*, *icbt*, and *icbtep* are treated as no-operations when they report Data Storage or Data TLB Miss exceptions, instead of being allowed to cause interrupts. However, these instructions are allowed to cause Debug interrupts, even when they would otherwise have been no-op'ed due to a Data Storage or Data TLB Miss exception.
- *dcbtst*, *dcbtstls*, *dcbtstep*, *dcbz*, *dcbzep*, *dcbi*, *dcbf*, *dcbfep*, *dcbz*, *dcbst*, and *dcbstep* are all considered writes with respect to

debug events. Note that *dcbf*, *dcbfep*, *dcbst*, and *dcbstep* are considered reads with respect to Data Storage exceptions, since they do not actually change the data at a given address. However, since the execution of these instructions may result in write activity on the data bus, they are treated as writes with respect to debug events. Note also that *dcbtst* and *dcbtstep* are treated as no-operations when they report Data Storage or Data TLB Miss exceptions, instead of being allowed to cause interrupts. However, these instructions are allowed to cause Debug interrupts, even when they would otherwise have been no-op'ed due to a Data Storage or Data TLB Miss exception.

Data Address Compare User/Supervisor Mode

$DBCR2_{DAC1US}$ specifies whether $DAC1R$ and $DAC1W$ debug events can occur in user mode or supervisor mode, or both.

$DBCR2_{DAC2US}$ specifies whether $DAC2R$ and $DAC2W$ debug events can occur in user mode or supervisor mode, or both.

Effective/Real Address Mode

$DBCR2_{DAC1ER}$ specifies whether effective addresses, real addresses, effective addresses and $MSR_{DS}=0$, or effective addresses and $MSR_{DS}=1$ are used in determining an address match on $DAC1R$ and $DAC1W$ debug events.

$DBCR2_{DAC2ER}$ specifies whether effective addresses, real addresses, effective addresses and $MSR_{DS}=0$, or effective addresses and $MSR_{DS}=1$ are used in determining an address match on $DAC2R$ and $DAC2W$ debug events.

Data Address Compare Mode

$DBCR2_{DAC12M}$ specifies whether all or some of the bits of the address of the data storage access must match the contents of the $DAC1$ or $DAC2$, whether the address must be inside a specific range specified by the $DAC1$ and $DAC2$ or outside a specific range specified by the $DAC1$ and $DAC2$ for a $DAC1R$, $DAC1W$, $DAC2R$ or $DAC2W$ debug event to occur.

There are four data address compare modes.

- *Exact address compare mode*
If the 64-bit address of the data storage access is equal to the value in the enabled Data Address Compare Register, a data address match occurs.

For 64-bit implementations, the addresses are masked to compare only bits 32:63 when the thread is executing in 32-bit mode.

- *Address bit match mode*

If the address of the data storage access, ANDed with the contents of the DAC2, are equal to the contents of the DAC1, also ANDed with the contents of the DAC2, a data address match occurs.

For 64-bit implementations, the addresses are masked to compare only bits 32:63 when the thread is executing in 32-bit mode.

- *Inclusive address range compare mode*

If the 64-bit address of the data storage access is greater than or equal to the contents of the DAC1 and less than the contents of the DAC2, a data address match occurs.

For 64-bit implementations, the addresses are masked to compare only bits 32:63 when the thread is executing in 32-bit mode.

- *Exclusive address range compare mode*

If the 64-bit address of the data storage access is less than the contents of the DAC1 or greater than or equal to the contents of the DAC2, a data address match occurs.

For 64-bit implementations, the addresses are masked to compare only bits 32:63 when the thread is executing in 32-bit mode.

Data Value Compare Mode

DBCR2_{DVC1M} and DBCR2_{DVC1BE} specify whether and how the data value being accessed by the storage access must match the contents of the DVC1 for a DAC1R or DAC1W debug event to occur.

DBCR2_{DVC2M} and DBCR2_{DVC2BE} specify whether and how the data value being accessed by the storage access must match the contents of the DVC2 for a DAC2R or DAC2W debug event to occur.

The description of DBCR0 (see Section 10.5.1.1) and DBCR2 (see Section 10.5.1.3) and the modes for detecting Data Address Compare debug events. Data Address Compare debug events can occur regardless of the setting of MSR_{DE} or DBCR0_{IDM}.

When an Data Address Compare debug event occurs, the corresponding DBSR_{DAC1R}, DBSR_{DAC1W}, DBSR_{DAC2R}, or DBSR_{DAC2W} bit or bits are set to 1 to record the debug exception. If MSR_{DE}=0, DBSR_{IDE} is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 (i.e. Debug interrupts are enabled) at the time of the Data Address Compare debug exception, a Debug interrupt will occur immediately (provided there

exists no higher priority exception which is enabled to cause an interrupt), the execution of the instruction causing the exception will be suppressed, and CSRR0/DSRR0 [Category: Embedded.Enhanced Debug will be set to the address of the excepting instruction. Depending on the type of instruction and/or the alignment of the data access, the instruction causing the exception may have been partially executed (see Section 7.7).

If MSR_{DE}=0 (i.e. Debug interrupts are disabled) at the time of the Data Address Compare debug exception, a Debug interrupt will not occur, and the instruction will complete execution (provided the instruction is not causing some other exception which will generate an enabled interrupt). Also, DBSR_{IDE} is set to indicate that the debug exception occurred while Debug interrupts were disabled by MSR_{DE}=0.

Later, if the debug exception has not been reset by clearing DBSR_{DAC1R}, DBSR_{DAC1W}, DBSR_{DAC2R}, DBSR_{DAC2W}, and MSR_{DE} is set to 1, a delayed Debug interrupt will occur. In this case, CSRR0/DSRR0 [Category: Embedded.Enhanced Debug will contain the address of the instruction after the one which enabled the Debug interrupt by setting MSR_{DE} to 1. Software in the Debug interrupt handler can observe DBSR_{IDE} to determine how to interpret the value in CSRR0/DSRR0 [Category: Embedded.Enhanced Debug.

10.4.3 Trap Debug Event

A Trap debug event (TRAP) occurs if DBCR0_{TRAP}=1 (i.e. Trap debug events are enabled) and a *Trap* instruction (*tw*, *twi*, *td*, *tdi*) is executed and the conditions specified by the instruction for the trap are met. The event can occur regardless of the setting of MSR_{DE} or DBCR0_{IDM}.

When a Trap debug event occurs, DBSR_{TR} is set to 1 to record the debug exception. If MSR_{DE}=0, DBSR_{IDE} is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 (i.e. Debug interrupts are enabled) at the time of the Trap debug exception, a Debug interrupt will occur immediately (provided there exists no higher priority exception which is enabled to cause an interrupt), and CSRR0/DSRR0 [Category: Embedded.Enhanced Debug] will be set to the address of the excepting instruction.

If MSR_{DE}=0 (i.e. Debug interrupts are disabled) at the time of the Trap debug exception, a Debug interrupt will not occur, and a Trap exception type Program interrupt will occur instead if the trap condition is met.

Later, if the debug exception has not been reset by clearing DBSR_{TR}, and MSR_{DE} is set to 1, a delayed Debug interrupt will occur. In this case, CSRR0/DSRR0 [Category: Embedded.Enhanced Debug will contain the address of the instruction after the one which enabled the Debug interrupt by setting MSR_{DE} to 1. Software in the debug interrupt handler can observe

DBSR_{IDE} to determine how to interpret the value in CSRR0/DSRR0 [Category: Embedded.Enhanced Debug].

10.4.4 Branch Taken Debug Event

A Branch Taken debug event (BRT) occurs if DBCR0_{BRT}=1 (i.e. Branch Taken Debug events are enabled), execution is attempted of a branch instruction whose direction will be taken (that is, either an unconditional branch, or a conditional branch whose branch condition is met), and MSR_{DE}=1.

Branch Taken debug events are not recognized if MSR_{DE}=0 at the time of the execution of the branch instruction and thus DBSR_{IDE} can not be set by a Branch Taken debug event. This is because branch instructions occur very frequently. Allowing these common events to be recorded as exceptions in the DBSR while debug interrupts are disabled via MSR_{DE} would result in an inordinate number of imprecise Debug interrupts.

When a Branch Taken debug event occurs, the DBSR_{BRT} bit is set to 1 to record the debug exception and a Debug interrupt will occur immediately (provided there exists no higher priority exception which is enabled to cause an interrupt). The execution of the instruction causing the exception will be suppressed, and CSRR0/DSRR0 [Category: Embedded.Enhanced Debug] will be set to the address of the excepting instruction.

10.4.5 Instruction Complete Debug Event

An Instruction Complete debug event (ICMP) occurs if DBCR0_{ICMP}=1 (i.e. Instruction Complete debug events are enabled), execution of any instruction is completed, and MSR_{DE}=1. Note that if execution of an instruction is suppressed due to the instruction causing some other exception which is enabled to generate an interrupt, then the attempted execution of that instruction does not cause an Instruction Complete debug event. The **sc** instruction does not fall into the type of an instruction whose execution is suppressed, since the instruction actually completes execution and then generates a System Call interrupt. In this case, the Instruction Complete debug exception will also be set.

Instruction Complete debug events are not recognized if MSR_{DE}=0 at the time of the execution of the instruction, DBSR_{IDE} can not be set by an ICMP debug event. This is because allowing the common event of Instruction Completion to be recorded as an exception in the DBSR while Debug interrupts are disabled via MSR_{DE} would mean that the Debug interrupt handler software would receive an inordinate number of imprecise Debug interrupts every time Debug interrupts were re-enabled via MSR_{DE}.

When an Instruction Complete debug event occurs, DBSR_{ICMP} is set to 1 to record the debug exception, a Debug interrupt will occur immediately (provided there exists no higher priority exception which is enabled to cause an interrupt), and CSRR0/DSRR0 [Category: Embedded.Enhanced Debug] will be set to the address of the instruction after the one causing the Instruction Complete debug exception.

10.4.6 Interrupt Taken Debug Event

10.4.6.1 Causes of Interrupt Taken Debug Events

Only base class interrupts can cause an Interrupt Taken debug event. If the Embedded.Enhanced Debug category is not supported or is supported and not enabled, all other interrupts automatically clear MSR_{DE}, and thus would always prevent the associated Debug interrupt from occurring precisely. If the Embedded.Enhanced Debug category is supported and enabled, then critical class interrupts do not automatically clear MSR_{DE}, but they cause Critical Interrupt Taken debug events instead of Interrupt Taken debug events.

Also, if the Embedded.Enhanced Debug category is not supported or is supported and not enabled, Debug interrupts themselves are critical class interrupts, and thus any Debug interrupt (for any other debug event) would always end up setting the additional exception of DBSR_{IRPT} upon entry to the Debug interrupt handler. At this point, the Debug interrupt handler would be unable to determine whether or not the Interrupt Taken debug event was related to the original debug event.

10.4.6.2 Interrupt Taken Debug Event Description

An Interrupt Taken debug event (IRPT) occurs if DBCR0_{IRPT}=1 (i.e. Interrupt Taken debug events are enabled) and a base class interrupt occurs. Interrupt Taken debug events can occur regardless of the setting of MSR_{DE}.

When an Interrupt Taken debug event occurs, DBSR_{IRPT} is set to 1 to record the debug exception. If MSR_{DE}=0, DBSR_{IDE} is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 (i.e. Debug interrupts are enabled) at the time of the Interrupt Taken debug event, a Debug interrupt will occur immediately (provided there exists no higher priority exception which is enabled to cause an interrupt), and Critical Save/Restore Register 0/Debug Save/Restore Register 0 [Category: Embedded.Enhanced Debug] will be set to the address of the interrupt vector which caused the Interrupt Taken

debug event. No instructions at the base interrupt handler will have been executed.

If $MSR_{DE}=0$ (i.e. Debug interrupts are disabled) at the time of the Interrupt Taken debug event, a Debug interrupt will not occur, and the handler for the interrupt which caused the Interrupt Taken debug event will be allowed to execute.

Later, if the debug exception has not been reset by clearing $DBSR_{IRPT}$, and MSR_{DE} is set to 1, a delayed Debug interrupt will occur. In this case, $CSRR0/DSRR0$ [Category: Embedded.Enhanced Debug] will contain the address of the instruction after the one which enabled the Debug interrupt by setting MSR_{DE} to 1. Software in the Debug interrupt handler can observe the $DBSR_{IDE}$ bit to determine how to interpret the value in $CSRR0/DSRR0$ [Category: Embedded.Enhanced Debug].

10.4.7 Return Debug Event

A Return debug event (RET) occurs if $DBCRO_{RET}=1$ and an attempt is made to execute an *rfi*. Return debug events can occur regardless of the setting of MSR_{DE} .

When a Return debug event occurs, $DBSR_{RET}$ is set to 1 to record the debug exception. If $MSR_{DE}=0$, $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If $MSR_{DE}=1$ at the time of the Return Debug event, a Debug interrupt will occur immediately, and $CSRR0/DSRR0$ [Category: Embedded.Enhanced Debug] will be set to the address of the *rfi*.

If $MSR_{DE}=0$ at the time of the Return Debug event, a Debug interrupt will not occur.

Later, if the Debug exception has not been reset by clearing $DBSR_{RET}$, and MSR_{DE} is set to 1, a delayed imprecise Debug interrupt will occur. In this case, $CSRR0/DSRR0$ [Category: Embedded.Enhanced Debug] will contain the address of the instruction after the one which enabled the Debug interrupt by setting MSR_{DE} to 1. An imprecise Debug interrupt can be caused by executing an *rfi* when $DBCRO_{RET}=1$ and $MSR_{DE}=0$, and the execution of that *rfi* happens to cause MSR_{DE} to be set to 1. Software in the Debug interrupt handler can observe the $DBSR_{IDE}$ bit to determine how to interpret the value in $CSRR0/DSRR0$ [Category: Embedded.Enhanced Debug].

10.4.8 Unconditional Debug Event

An Unconditional debug event (UDE) occurs when the Unconditional Debug Event (UDE) signal is activated by the debug mechanism. The exact definition of the UDE signal and how it is activated is implementation-dependent. The Unconditional debug event is the only debug event which does not have a corresponding enable bit for the event in $DBCRO$ (hence the name of

the event). The Unconditional debug event can occur regardless of the setting of MSR_{DE} .

When an Unconditional debug event occurs, the $DBSR_{UDE}$ bit is set to 1 to record the Debug exception. If $MSR_{DE}=0$, $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If $MSR_{DE}=1$ (i.e. Debug interrupts are enabled) at the time of the Unconditional Debug exception, a Debug interrupt will occur immediately (provided there exists no higher priority exception which is enabled to cause an interrupt), and $CSRR0/DSRR0$ [Category: Embedded.Enhanced Debug] will be set to the address of the instruction which would have executed next had the interrupt not occurred.

If $MSR_{DE}=0$ (i.e. Debug interrupts are disabled) at the time of the Unconditional Debug exception, a Debug interrupt will not occur.

Later, if the Unconditional Debug exception has not been reset by clearing $DBSR_{UDE}$, and MSR_{DE} is set to 1, a delayed Debug interrupt will occur. In this case, $CSRR0/DSRR0$ [Category: Embedded.Enhanced Debug] will contain the address of the instruction after the one which enabled the Debug interrupt by setting MSR_{DE} to 1. Software in the Debug interrupt handler can observe $DBSR_{IDE}$ to determine how to interpret the value in $CSRR0/DSRR0$ [Category: Embedded.Enhanced Debug].

10.4.9 Critical Interrupt Taken Debug Event [Category: Embedded.Enhanced Debug]

A Critical Interrupt Taken debug event (CIRPT) occurs if $DBCRO_{CIRPT} = 1$ (i.e. Critical Interrupt Taken debug events are enabled) and a critical interrupt occurs. A critical interrupt is any interrupt that saves state in $CSRR0$ and $CSRR1$ when the interrupt is taken. Critical Interrupt Taken debug events can occur regardless of the setting of MSR_{DE} .

When a Critical Interrupt Taken debug event occurs, $DBSR_{CIRPT}$ is set to 1 to record the debug event. If $MSR_{DE}=0$, $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If $MSR_{DE} = 1$ (i.e. Debug Interrupts are enabled) at the time of the Critical Interrupt Taken debug event, a Debug Interrupt will occur immediately (provided there is no higher priority exception which is enabled to cause an interrupt), and $DSRR0$ will be set to the address of the first instruction of the critical interrupt handler. No instructions at the critical interrupt handler will have been executed.

If $MSR_{DE} = 0$ (i.e. Debug Interrupts are disabled) at the time of the Critical Interrupt Taken debug event, a Debug Interrupt will not occur, and the handler for the critical interrupt which caused the debug event will be

allowed to execute normally. Later, if the debug exception has not been reset by clearing $DBSR_{CIRPT}$ and MSR_{DE} is set to 1, a delayed Debug Interrupt will occur. In this case $DSRR0$ will contain the address of the instruction after the one that set $MSR_{DE} = 1$. Software in the Debug Interrupt handler can observe $DBSR_{IDE}$ to determine how to interpret the value in $DSRR0$.

10.4.10 Critical Interrupt Return Debug Event [Category: Embedded.Enhanced Debug]

A Critical Interrupt Return debug event (CRET) occurs if $DBCR0_{CRET} = 1$ (i.e. Critical Interrupt Return debug events are enabled) and an attempt is made to execute an *rfci* instruction. Critical Interrupt Return debug events can occur regardless of the setting of MSR_{DE} .

When a Critical Interrupt Return debug event occurs, $DBSR_{CRET}$ is set to 1 to record the debug event. If $MSR_{DE}=0$, $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If $MSR_{DE} = 1$ (i.e. Debug Interrupts are enabled) at the time of the Critical Interrupt Return debug event, a Debug Interrupt will occur immediately (provided there is no higher priority exception which is enabled to cause an interrupt), and $DSRR0$ will be set to the address of the *rfci* instruction.

If $MSR_{DE} = 0$ (i.e. Debug Interrupts are disabled) at the time of the Critical Interrupt Return debug event, a Debug Interrupt will not occur. Later, if the debug exception has not been reset by clearing $DBSR_{CRET}$ and MSR_{DE} is set to 1, a delayed Debug Interrupt will occur. In this case $DSRR0$ will contain the address of the instruction after the one that set $MSR_{DE} = 1$. An imprecise Debug Interrupt can be caused by executing an *rfci* when $DBCR0_{CRET} = 1$ and $MSR_{DE} = 0$, and the execution of the *rfci* happens to cause MSR_{DE} to be set to 1. Software in the Debug Interrupt handler can observe $DBSR_{IDE}$ to determine how to interpret the value in $DSRR0$.

10.5 Debug Registers

This section describes debug-related registers that are accessible to software. These registers are intended for use by special debug tools and debug software, and not by general application or operating system code.

10.5.1 Debug Control Registers

Debug Control Register 0 (DBCR0), Debug Control Register 1 (DBCR1), and Debug Control Register 2 (DBCR2) are each 32-bit registers. Bits of DBCR0, DBCR1, and DBCR2 are numbered 32 (most-significant bit) to 63 (least-significant bit). DBCR0, DBCR1,

and DBCR2 are used to enable debug events, reset the thread, control timer operation during debug events, and set the debug mode of the thread.

10.5.1.1 Debug Control Register 0 (DBCR0)

The contents of the DBCR0 can be read into bits 32:63 of register RT using *mfspir RT, DBCR0*, setting bits 0:31 of RT to 0. The contents of bits 32:63 of register RS can be written to the DBCR0 using *mtspir DBCR0, RS*. The bit definitions for DBCR0 are shown below.

Bit(s)	Description
32	External Debug Mode (EDM) [Category: Embedded.Enhanced Debug] The EDM bit is a read-only bit that reflects whether the thread is controlled by an external debug facility. When EDM is set, internal debug mode is suppressed and the taking of debug interrupts does not occur. 0 The thread is not in external debug mode. 1 The thread is in external debug mode.
33	Internal Debug Mode (IDM) 0 Debug interrupts are disabled. 1 If $MSR_{DE}=1$, then the occurrence of a debug event or the recording of an earlier debug event in the Debug Status Register when $MSR_{DE}=0$ or $DBCR0_{IDM}=0$ will cause a Debug interrupt.

Programming Note

Software must clear debug event status in the Debug Status Register in the Debug interrupt handler when a Debug interrupt is taken before re-enabling interrupts via MSR_{DE} . Otherwise, redundant Debug interrupts will be taken for the same debug event.

34:35	Reset (RST) 00 No action 01 Implementation-specific 10 Implementation-specific 11 Implementation-specific Warning: Writing 0b01, 0b10, or 0b11 to these bits may cause a thread reset to occur.
36	Instruction Completion Debug Event (ICMP) 0 ICMP debug events are disabled 1 ICMP debug events are enabled

Note: Instruction Completion will not cause an ICMP debug event if $MSR_{DE}=0$.

IAC3 debug events can occur only if the address of the instruction fetch is equal to the value specified in IAC3.

IAC4 debug events can occur only if the address of the instruction fetch is equal to the value specified in IAC4.

01 Address bit match

IAC3 and IAC4 debug events can occur only if the address of the data storage access, ANDed with the contents of IAC4 are equal to the contents of IAC3, also ANDed with the contents of IAC4.

If $IAC3US \neq IAC4US$ or $IAC3ER \neq IAC4ER$, results are boundedly undefined.

10 Inclusive address range compare

IAC3 and IAC4 debug events can occur only if the address of the instruction fetch is greater than or equal to the value specified in IAC3 and less than the value specified in IAC4.

If $IAC3US \neq IAC4US$ or $IAC3ER \neq IAC4ER$, results are boundedly undefined.

11 Exclusive address range compare

IAC3 and IAC4 debug events can occur only if the address of the instruction fetch is less than the value specified in IAC3 or is greater than or equal to the value specified in IAC4.

If $IAC3US \neq IAC4US$ or $IAC3ER \neq IAC4ER$, results are boundedly undefined.

58:63 Reserved

This register is hypervisor privileged.

10.5.1.3 Debug Control Register 2 (DBCR2)

The contents of the DBCR2 can be copied into bits 32:63 register RT using *mfspir RT, DBCR2*, setting bits 0:31 of register RT to 0. The contents of bits 32:63 of a register RS can be written to the DBCR2 using *mtspir DBCR2, RS*. The bit definitions for DBCR2 are shown below.

Bit(s) Description

32:33 **Data Address Compare 1 User/Supervisor Mode** (DAC1US)

- 00 DAC1 debug events can occur
- 01 Reserved
- 10 DAC1 debug events can occur only if $MSR_{PR}=0$

11 DAC1 debug events can occur only if $MSR_{PR}=1$

34:35 **Data Address Compare 1 Effective/Real Mode** (DAC1ER)

- 00 DAC1 debug events are based on effective addresses
- 01 DAC1 debug events are based on real addresses
- 10 DAC1 debug events are based on effective addresses and can occur only if $MSR_{DS}=0$
- 11 DAC1 debug events are based on effective addresses and can occur only if $MSR_{DS}=1$

36:37 **Data Address Compare 2 User/Supervisor Mode** (DAC2US)

- 00 DAC2 debug events can occur
- 01 Reserved
- 10 DAC2 debug events can occur only if $MSR_{PR}=0$
- 11 DAC2 debug events can occur only if $MSR_{PR}=1$

38:39 **Data Address Compare 2 Effective/Real Mode** (DAC2ER)

- 00 DAC2 debug events are based on effective addresses
- 01 DAC2 debug events are based on real addresses
- 10 DAC2 debug events are based on effective addresses and can occur only if $MSR_{DS}=0$
- 11 DAC2 debug events are based on effective addresses and can occur only if $MSR_{DS}=1$

40:41 **Data Address Compare 1/2 Mode** (DAC12M)

00 Exact address compare

DAC1 debug events can occur only if the address of the data storage access is equal to the value specified in DAC1.

DAC2 debug events can occur only if the address of the data storage access is equal to the value specified in DAC2.

01 Address bit match

DAC1 and DAC2 debug events can occur only if the address of the data storage access, ANDed with the contents of DAC2 are equal to the contents of DAC1, also ANDed with the contents of DAC2.

If $DAC1US \neq DAC2US$ or $DAC1ER \neq DAC2ER$, results are boundedly undefined.

10 Inclusive address range compare

DAC1 and DAC2 debug events can occur only if the address of the data storage access is greater than or equal to the value specified in DAC1 and less than the value specified in DAC2.

If $DAC1US \neq DAC2US$ or $DAC1ER \neq DAC2ER$, results are boundedly undefined.

11 Exclusive address range compare

DAC1 and DAC2 debug events can occur only if the address of the data storage access is less than the value specified in DAC1 or is greater than or equal to the value specified in DAC2.

If $DAC1US \neq DAC2US$ or $DAC1ER \neq DAC2ER$, results are boundedly undefined.

42:43 Reserved

44:45 **Data Value Compare 1 Mode** (DVC1M)

00 DAC1 debug events can occur

01 DAC1 debug events can occur only when all bytes specified in $DBCR2_{DVC1BE}$ in the data value of the data storage access match their corresponding bytes in DVC1

10 DAC1 debug events can occur only when at least one of the bytes specified in $DBCR2_{DVC1BE}$ in the data value of the data storage access matches its corresponding byte in DVC1

11 DAC1 debug events can occur only when all bytes specified in $DBCR2_{DVC1BE}$ within at least one of the halfwords of the data value of the data storage access matches their corresponding bytes in DVC1

46:47 **Data Value Compare 2 Mode** (DVC2M)

00 DAC2 debug events can occur

01 DAC2 debug events can occur only when all bytes specified in $DBCR2_{DVC2BE}$ in the data value of the data storage access match their corresponding bytes in DVC2

10 DAC2 debug events can occur only when at least one of the bytes specified in $DBCR2_{DVC2BE}$ in the data value of the data storage access matches its corresponding byte in DVC2

11 DAC2 debug events can occur only when all bytes specified in $DBCR2_{DVC2BE}$ within at least one of the halfwords of the data value of the data storage access matches their corresponding bytes in DVC2

48:55 **Data Value Compare 1 Byte Enables** (DVC1BE)

Specifies which bytes in the aligned data value being read or written by the storage access are compared to the corresponding bytes in DVC1.

56:63 **Data Value Compare 2 Byte Enables** (DVC2BE)

Specifies which bytes in the aligned data value being read or written by the storage access are compared to the corresponding bytes in DVC2

This register is hypervisor privileged.

10.5.2 Debug Status Register

The Debug Status Register (DBSR) is a 32-bit register and contains status on debug events and the most recent thread reset.

The DBSR is set via hardware, and read and cleared via software. The contents of the DBSR can be read into bits 32:63 of a register RT using the *mfspir* instruction, setting bits 0:31 of RT to zero. Bits in the DBSR can be cleared using the *mtspir* instruction. Clearing is done by writing bits 32:63 of a register to the DBSR with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write-data to the DBSR is not direct data, but a mask. A 1 causes the bit to be cleared, and a 0 has no effect.

The bit definitions for the DBSR are shown below:

Bit(s) Description

32 **Imprecise Debug Event** (IDE)

Set to 1 if $MSR_{DE}=0$ and a debug event causes its respective Debug Status Register bit to be set to 1.

33 **Unconditional Debug Event** (UDE)

Set to 1 if an Unconditional debug event occurred. See Section 10.4.8.

34:35 **Most Recent Reset** (MRR)

Set to one of three values when a reset occurs. These two bits are undefined at power-up.

00 No reset occurred since these bits last cleared by software

01 Implementation-dependent reset information

10 Implementation-dependent reset information

11 Implementation-dependent reset information

36 **Instruction Complete Debug Event** (ICMP)

Set to 1 if an Instruction Completion debug event occurred and $DBCR0_{ICMP}=1$. See Section 10.4.5.

37 **Branch Taken Debug Event** (BRT)

	Set to 1 if a Branch Taken debug event occurred and $DBCRO_{BRT}=1$. See Section 10.4.4.		Set to 1 if a Return debug event occurred and $DBCRO_{RET}=1$. See Section 10.4.2.
38	Interrupt Taken Debug Event (IRPT) Set to 1 if an Interrupt Taken debug event occurred and $DBCRO_{IRPT}=1$. See Section 10.4.6.	49:52	Reserved
39	Trap Instruction Debug Event (TRAP) Set to 1 if a Trap Instruction debug event occurred and $DBCRO_{TRAP}=1$. See Section 10.4.3.	53:56	Implementation-dependent
40	Instruction Address Compare 1 Debug Event (IAC1) Set to 1 if an IAC1 debug event occurred and $DBCRO_{IAC1}=1$. See Section 10.4.1.	57	Critical Interrupt Taken Debug Event (CIRPT) [Category: Embedded.Enhanced Debug] A Critical Interrupt Taken Debug Event occurs when $DBCRO_{CIRPT}=1$ and a critical interrupt (any interrupt that uses the critical class, i.e. uses CSRR0 and CSRR1) occurs. 0 Critical interrupt taken debug events are disabled. 1 Critical interrupt taken debug events are enabled.
41	Instruction Address Compare 2 Debug Event (IAC2) Set to 1 if an IAC2 debug event occurred and $DBCRO_{IAC2}=1$. See Section 10.4.1.	58	Critical Interrupt Return Debug Event (CRET) [Category: Embedded.Enhanced Debug] A Critical Interrupt Return Debug Event occurs when $DBCRO_{CRET}=1$ and a return from critical interrupt (an <i>rftci</i> instruction is executed) occurs. 0 Critical interrupt return debug events are disabled. 1 Critical interrupt return debug events are enabled.
42	Instruction Address Compare 3 Debug Event (IAC3) Set to 1 if an IAC3 debug event occurred and $DBCRO_{IAC3}=1$. See Section 10.4.1.	59:63	Implementation-dependent
43	Instruction Address Compare 4 Debug Event (IAC4) Set to 1 if an IAC4 debug event occurred and $DBCRO_{IAC4}=1$. See Section 10.4.1.		This register is hypervisor privileged.
44	Data Address Compare 1 Read Debug Event (DAC1R) Set to 1 if a read-type DAC1 debug event occurred and $DBCRO_{DAC1}=0b10$ or $DBCRO_{DAC1}=0b11$. See Section 10.4.2.		
45	Data Address Compare 1 Write Debug Event (DAC1W) Set to 1 if a write-type DAC1 debug event occurred and $DBCRO_{DAC1}=0b01$ or $DBCRO_{DAC1}=0b11$. See Section 10.4.2.		
46	Data Address Compare 2 Read Debug Event (DAC2R) Set to 1 if a read-type DAC2 debug event occurred and $DBCRO_{DAC2}=0b10$ or $DBCRO_{DAC2}=0b11$. See Section 10.4.2.		
47	Data Address Compare 2 Write Debug Event (DAC2W) Set to 1 if a write-type DAC2 debug event occurred and $DBCRO_{DAC2}=0b01$ or $DBCRO_{DAC2}=0b11$. See Section 10.4.2.		
48	Return Debug Event (RET)		

10.5.3 Debug Status Register Write Register (DBSRWR)

The Debug Status Register Write Register (DBSRWR) allows a hypervisor state program to write the contents of the Debug Status Register (see Section 10.5.2, “Debug Status Register”). The format of the DBSRWR is shown in Figure 69 below.

Figure 69. Debug Status Register Write Register

The DBSRWR is provided as a means to restore the contents of the DBSR on a partition switch.

The DBSRWR is hypervisor privileged.

Writing DBSRWR changes the value in the DBSR. Writing non-zero bits may enable an imprecise Debug exception which may cause later imprecise Debug Interrupts. In order to correctly write DBSRWR, software should ensure that $MSR_{DE} = 0$ when the value is written and perform a context synchronizing operation before setting MSR_{DE} to 1.

10.5.4 Instruction Address Compare Registers

The Instruction Address Compare Register 1, 2, 3, and 4 (IAC1, IAC2, IAC3, and IAC4 respectively) are each 64-bits, with bit 63 being reserved.

A debug event may be enabled to occur upon an attempt to execute an instruction from an address specified in either IAC1, IAC2, IAC3, or IAC4, inside or outside a range specified by IAC1 and IAC2 or, inside or outside a range specified by IAC3 and IAC4, or to blocks of addresses specified by the combination of the IAC1 and IAC2, or to blocks of addresses specified by the combination of the IAC3 and IAC4. Since all instruction addresses are required to be word-aligned, the two low-order bits of the Instruction Address Compare Registers are reserved and do not participate in the comparison to the instruction address (see Section 10.4.1 on page 1079).

The contents of the Instruction Address Compare i Register (where $i=\{1,2,3, \text{ or } 4\}$) can be read into register RT using *mf spr RT,IACi*. The contents of register RS can be written to the Instruction Address Compare i Register using *mt spr IACi,RS*.

This register is hypervisor privileged.

10.5.5 Data Address Compare Registers

The Data Address Compare Register 1 and 2 (DAC1 and DAC2 respectively) are each 64-bits.

A debug event may be enabled to occur upon loads, stores, or cache operations to an address specified in either the DAC1 or DAC2, inside or outside a range specified by the DAC1 and DAC2, or to blocks of addresses specified by the combination of the DAC1 and DAC1 (see Section 10.4.2).

The contents of the Data Address Compare i Register (where $i=\{1 \text{ or } 2\}$) can be read into register RT using *mf spr RT,DACi*. The contents of register RS can be written to the Data Address Compare i Register using *mt spr DACi,RS*.

The contents of the DAC1 or DAC2 are compared to the address generated by a data storage access instruction.

These registers are hypervisor privileged.

10.5.6 Data Value Compare Registers

The Data Value Compare Register 1 and 2 (DVC1 and DVC2 respectively) are each 64-bits.

A DAC1R, DAC1W, DAC2R, or DAC2W debug event may be enabled to occur upon loads or stores of a specific data value specified in either or both of the DVC1 and DVC2. $DBCR2_{DVC1M}$ and $DBCR2_{DVC1BE}$ control how the contents of the DVC1 is compared with the value and $DBCR2_{DVC2M}$ and $DBCR2_{DVC2BE}$ control how the contents of the DVC2 is compared with the value (see Section 10.4.2 and Section 10.5.1.3).

The contents of the Data Value Compare i Register (where $i=\{1 \text{ or } 2\}$) can be read into register RT using *mf spr RT,DVCi*. The contents of register RS can be written to the Data Value Compare i Register using *mt spr DVCi,RS*.

These registers are hypervisor privileged.

10.6 Debugger Notify Halt Instruction [Category: Embedded.Enhanced Debug]

The ***dnh*** instruction provides the means for the transfer of information between the thread and an implementation-dependent external debug facility. ***dnh*** also causes the thread to stop fetching and executing instructions.

Debugger Notify Halt ***XFX-form***

dnh DUI,DUIS

19	DUI	DUIS	198	/
0	6	11	21	31

```

if enabled by implementation-dependent means
then
    implementation-dependent register ← DUI
    halt thread
else
    illegal instruction exception

```

Execution of the ***dnh*** instruction causes the thread to stop fetching instructions and taking interrupts if execution of the instruction has been enabled. The contents of the DUI field are sent to the external debug facility to identify the reason for the halt.

If execution of the ***dnh*** instruction has not been previously enabled, executing the ***dnh*** instruction produces an Illegal Instruction exception. The means by which execution of the ***dnh*** instruction is enabled is implementation-dependent.

The current state of the debug facility, whether the thread is in IDM or EDM mode has no effect on the execution of the ***dnh*** instruction.

The instruction is context synchronizing.

Programming Note

The DUIS field in the instruction may be used to pass information to an external debug facility. After the ***dnh*** instruction has executed, the instruction itself can be read back by the Illegal Instruction Interrupt handler or the external debug facility if the contents of the DUIS field are of interest. If the thread entered the Illegal Instruction Interrupt handler, software can use SRR0 to obtain the address of the ***dnh*** instruction which caused the handler to be invoked.

Special Registers Altered:

None

Chapter 11. Processor Control [Category: Embedded.Processor Control]

11.1 Overview	1093	11.2.2.3 Guest Doorbell Critical Message Filtering [Category: Embedded.Hypervisor]	1096
11.2 Programming Model	1093	11.2.2.4 Guest Doorbell Machine Check Message Filtering [Category: Embedded.Hypervisor]	1096
11.2.1 Message Handling and Filtering	1093	11.3 Processor Control Instructions	1098
11.2.2 Doorbell Message Filtering	1094		
11.2.2.1 Doorbell Critical Message Filtering	1095		
11.2.2.2 Guest Doorbell Message Filtering [Category: Embedded.Hypervisor]	1095		

11.1 Overview

The Processor Control facility provides a mechanism for threads within a coherence domain to send messages to all devices in the coherence domain. The facility provides a mechanism for sending interrupts that are not dependent on the interrupt controller to threads and allows message filtering by the threads that receive the message.

The Processor Control facility is also useful for sending messages to a device that provides specialized services such as secure boot operations controlled by a security device.

The Processor Control facility defines how threads send messages and what actions threads take on the receipt of a message. The actions taken by devices other than threads are not defined.

11.2 Programming Model

Threads initiate a message by executing the *msgsnd* instruction and specifying a message type and message payload in a general purpose register. Sending a message causes the message to be sent to all the devices, including the sending thread, in the coherence domain in a reliable manner.

Each device receives all messages that are sent. The actions that a device takes are dependent on the message type and payload. There are no restrictions on what messages a thread can send.

To provide inter thread interrupt capability the following *doorbell* message types are defined:

- *Processor Doorbell*
- *Processor Doorbell Critical*
- *Guest Processor Doorbell* <E.HV>
- *Guest Processor Doorbell Critical* <E.HV>
- *Guest Processor Doorbell Machine Check* <E.HV>

A doorbell message causes an interrupt to occur on threads when the message is received and the thread determines through examination of the payload that the message should be accepted. The examination of the payload for this purpose is termed *filtering*. The acceptance of a doorbell message causes an exception to be generated on the accepting thread.

Threads accept and filter messages defined in Section 11.2.1. Threads may also accept other implementation-dependent defined messages.

11.2.1 Message Handling and Filtering

Threads filter, accept, and handle message types defined as follows. The message type is specified in the message and is determined by the contents of register RB_{32:36} used as the operand in the *msgsnd* instruction. The message type is interpreted as follows:

Value	Description
-------	-------------

- | | |
|---|---|
| 0 | <i>Doorbell Interrupt</i> (DBELL)
A Processor Doorbell exception is generated on the thread when the thread has filtered the message based on the payload and has |
|---|---|

determined that it should accept the message. A Processor Doorbell Interrupt occurs when no higher priority exception exists, a Processor Doorbell exception exists, and the interrupt is enabled ($MSR_{EE}=1$). If category Embedded.Hypervisor is supported, the interrupt is enabled if ($MSR_{EE}=1$ or $MSR_{GS}=1$).

- 1 **Doorbell Critical Interrupt** (DBELL_CRIT)
A Processor Doorbell Critical exception is generated on the thread when the thread has filtered the message based on the payload and has determined that it should accept the message. A Processor Doorbell Critical Interrupt occurs when no higher priority exception exists, a Processor Doorbell Critical exception exists, and the interrupt is enabled ($MSR_{CE}=1$). If category Embedded.Hypervisor is supported, the interrupt is enabled if ($MSR_{CE}=1$ or $MSR_{GS}=1$).
- 2 **Guest Doorbell Interrupt** (G_DBELL) <E.HV>
A Guest Processor Doorbell exception is generated on the thread when the thread has filtered the message based on the payload and has determined that it should accept the message. A Guest Processor Doorbell Interrupt occurs when no higher priority exception exists, a Guest Processor Doorbell exception exists, and the interrupt is enabled ($MSR_{EE}=1$ and $MSR_{GS}=1$).
- 3 **Guest Doorbell Interrupt Critical** (G_DBELL_CRIT) <E.HV>
A Guest Processor Doorbell Critical exception is generated on the thread when the thread has filtered the message based on the payload and has determined that it should accept the message. A Guest Processor Doorbell Critical Interrupt occurs when no higher priority exception exists, a Guest Processor Doorbell Critical exception exists, and the interrupt is enabled ($MSR_{CE}=1$ and $MSR_{GS}=1$).
- 4 **Guest Doorbell Interrupt Machine Check** (G_DBELL_MC) <E.HV>
A Guest Processor Doorbell Machine Check exception is generated on the thread when the thread has filtered the message based on the payload and has determined that it should accept the message. A Guest Processor Doorbell Machine Check Interrupt occurs when no higher priority exception exists, a Guest Processor Doorbell Machine Check exception exists, and the interrupt is enabled ($MSR_{ME}=1$ and $MSR_{GS}=1$).

Message types other than these and their associated actions are implementation-dependent.

11.2.2 Doorbell Message Filtering

A thread receiving a DBELL message will filter the message and either ignore the message or accept the message and generate a Processor Doorbell exception based on the payload and the state of the thread at the time the message is received.

The payload is specified in the message and is determined by the contents of register $RB_{37:63}$ used as the operand in the *msgsnd* instruction. The payload bits are defined below.

Bit	Description
37	Broadcast (BRDCAST) If set, the message is accepted by all threads regardless of the value of the PIR register and the value of PIRTAG.
0	If the value of PIR and PIRTAG are equal a Processor Doorbell exception is generated.
1	A Processor Doorbell exception is generated regardless of the value of PIRTAG and PIR.
38:49	LPID Tag (LPIDTAG) <E.HV> The contents of this field are compared with the contents of the LPIDR. If LPIDTAG = 0, it matches all values in the LPIDR register.
50:63	PIR Tag (PIRTAG) The contents of this field are compared with bits 50:63 of the PIR register.

If category E.HV is supported by the thread on which a DBELL message is received, the message will only be accepted if it is for this partition ($payload_{LPIDTAG} = LPIDR$) or it is for all partitions ($payload_{LPIDTAG} = 0$) and it meets the additional criteria for acceptance below.

If a DBELL message is received by a thread, the message is accepted and a Processor Doorbell exception is generated if one of the following conditions exist:

- This is a broadcast message ($payload_{BRDCAST}=1$);
- The message is intended for this thread ($PIR_{50:63}=payload_{PIRTAG}$).

The exception condition remains until a Processor Doorbell Interrupt is taken, or a *msgclr* instruction is executed on the receiving thread with a message type of DBELL. A change to any of the filtering criteria (i.e. changing the PIR register) will not clear a pending Processor Doorbell exception.

DBELL messages are not cumulative. That is, if a DBELL message is accepted and the interrupt is pending because $MSR_{EE}=0$, additional DBELL messages that would be accepted are ignored until the Processor Doorbell exception is cleared by taking the interrupt or cleared by executing a *msgclr* with a message type of DBELL on the receiving thread.

The temporal relationship between when a DBELL message is sent and when it is received in a given thread is not defined.

11.2.2.1 Doorbell Critical Message Filtering

A thread receiving a DBELL_CRIT message type will filter the message and either ignore the message or accept the message and generate a Processor Doorbell Critical exception based on the payload and the state of the thread at the time the message is received.

The payload is specified in the message and is determined by the contents of register RB_{37:63} used as the operand in the *msgsnd* instruction. The payload bits are defined below.

Bit	Description
37	Broadcast (BRDCAST) If set, the message is accepted by all threads regardless of the value of the PIR register and the value of PIRTAG.
0	If the value of PIR and PIRTAG are equal a Processor Doorbell Critical exception is generated.
1	A Processor Doorbell Critical exception is generated regardless of the value of PIRTAG and PIR.
38:49	LPID Tag (LPIDTAG) <E.HV> The contents of this field are compared with the contents of the LPIDR. If LPIDTAG = 0, it matches all values in the LPIDR register.
50:63	PIR Tag (PIRTAG) The contents of this field are compared with bits 50:63 of the PIR register.

If category E.HV is supported by the thread on which a DBELL_CRIT message is received, the message will only be accepted if it is for this partition (payload_{LPIDTAG} = LPIDR) or it is for all partitions (payload_{LPIDTAG} = 0) and it meets the additional criteria for acceptance below.

If a DBELL_CRIT message is received by a thread, the message is accepted and a Processor Doorbell Critical exception is generated if one of the following conditions exist:

- This is a broadcast message (payload_{BRDCAST}=1);
- The message is intended for this thread (PIR_{50:63}=payload_{PIRTAG}).

DBELL_CRIT messages are not cumulative. That is, if a DBELL_CRIT message is accepted and the interrupt is pended because MSR_{CE}=0, additional DBELL_CRIT messages that would be accepted are ignored until the Processor Doorbell Critical exception is cleared by taking the interrupt or cleared by executing a *msgclr* with a message type of DBELL_CRIT on the receiving thread.

The temporal relationship between when a DBELL_CRIT message is sent and when it is received in a given thread is not defined.

The temporal relationship between when a DBELL_CRIT message is sent and when it is received in a given thread is not defined.

11.2.2.2 Guest Doorbell Message Filtering [Category: Embedded.Hypervisor]

A thread receiving a G_DBELL message type will filter the message and either ignore the message or accept the message and generate a Guest Processor Doorbell Critical exception based on the payload and the state of the thread at the time the message is received.

The payload is specified in the message and is determined by the contents of register RB_{37:63} used as the operand in the *msgsnd* instruction. The payload bits are defined below.

Bit	Description
37	Broadcast (BRDCAST) If set, the message is accepted by all threads regardless of the value of the GPIR register and the value of PIRTAG.
0	If the value of GPIR and PIRTAG are equal a Guest Processor Doorbell exception is generated.
1	A Guest Processor Doorbell exception is generated regardless of the value of PIRTAG and GPIR.
38:49	LPID Tag (LPIDTAG) The contents of this field are compared with the contents of the LPIDR. If LPIDTAG = 0, it matches all values in the LPIDR register.
50:63	PIR Tag (PIRTAG) The contents of this field are compared with bits 50:63 of the GPIR register.

When a G_DBELL message is received by a thread, the message will only be accepted if it is for this partition (payload_{LPIDTAG} = LPIDR) or it is for all partitions (payload_{LPIDTAG} = 0) and it meets the additional criteria for acceptance below.

The message is accepted and a Guest Processor Doorbell exception is generated if one of the following conditions exist:

- This is a broadcast message (payload_{BRDCAST}=1);
- The message is intended for this thread (GPIR_{50:63}=payload_{PIRTAG}).

G_DBELL messages are not cumulative. That is, if a G_DBELL message is accepted and the interrupt is pended because MSR_{CE}=0, additional G_DBELL messages that would be accepted are ignored until the Guest Processor Doorbell exception is cleared by taking the interrupt or cleared by executing a *msgclr* with a message type of G_DBELL on the receiving thread.

The temporal relationship between when a G_DBELL message is sent and when it is received in a given thread is not defined.

11.2.2.3 Guest Doorbell Critical Message Filtering [Category: Embedded.Hypervisor]

A thread receiving a G_DBELL_CRIT message type will filter the message and either ignore the message or accept the message and generate a Guest Processor Doorbell Critical exception based on the payload and the state of the thread at the time the message is received.

The payload is specified in the message and is determined by the contents of register RB_{37:63} used as the operand in the *msgsnd* instruction. The payload bits are defined below.

Bit	Description
37	Broadcast (BRDCAST) If set, the message is accepted by all threads regardless of the value of the GPIR register and the value of PIRTAG.
0	If the value of GPIR and PIRTAG are equal a Guest Processor Doorbell Critical exception is generated.
1	A Guest Processor Doorbell Critical exception is generated regardless of the value of PIRTAG and GPIR.
38:49	LPID Tag (LPIDTAG) The contents of this field are compared with the contents of the LPIDR. If LPIDTAG = 0, it matches all values in the LPIDR register.
50:63	PIR Tag (PIRTAG) The contents of this field are compared with bits 50:63 of the GPIR register.

When a G_DBELL_CRIT message is received by a thread, the message will only be accepted if it is for this partition (payload_{LPIDTAG} = LPIDR) or it is for all partitions (payload_{LPIDTAG} = 0) and it meets the additional criteria for acceptance below.

If a G_DBELL_CRIT message is received by a thread, the message is accepted and a Guest Processor Doorbell Critical exception is generated if one of the following conditions exist:

- This is a broadcast message (payload_{BRDCAST}=1);
- The message is intended for this thread (GPIR_{50:63}=payload_{PIRTAG}).

G_DBELL_CRIT messages are not cumulative. That is, if a G_DBELL_CRIT message is accepted and the interrupt is pended because MSR_{CE}=0, additional G_DBELL messages that would be accepted are ignored until the Guest Processor Doorbell Critical exception is cleared by taking the interrupt or cleared

by executing a *msgclr* with a message type of G_DBELL_CRIT on the receiving thread.

The temporal relationship between when a G_DBELL_CRIT message is sent and when it is received in a given thread is not defined.

11.2.2.4 Guest Doorbell Machine Check Message Filtering [Category: Embedded.Hypervisor]

A thread receiving a G_DBELL_MC message type will filter the message and either ignore the message or accept the message and generate a Guest Processor Doorbell Machine Check exception based on the payload and the state of the thread at the time the message is received.

The payload is specified in the message and is determined by the contents of register RB_{37:63} used as the operand in the *msgsnd* instruction. The payload bits are defined below.

Bit	Description
37	Broadcast (BRDCAST) If set, the message is accepted by all threads regardless of the value of the GPIR register and the value of PIRTAG.
0	If the value of GPIR and PIRTAG are equal a Guest Processor Doorbell Machine Check exception is generated.
1	A Guest Processor Doorbell Machine Check exception is generated regardless of the value of PIRTAG and GPIR.
38:49	LPID Tag (LPIDTAG) The contents of this field are compared with the contents of the LPIDR. If LPIDTAG = 0, it matches all values in the LPIDR register.
50:63	PIR Tag (PIRTAG) The contents of this field are compared with bits 50:63 of the GPIR register.

When a G_DBELL_MC message is received by a thread, the message will only be accepted if it is for this partition (payload_{LPIDTAG} = LPIDR) or it is for all partitions (payload_{LPIDTAG} = 0) and it meets the additional criteria for acceptance below.

If a G_DBELL_MC message is received by a thread, the message is accepted and a Guest Processor Doorbell Machine Check exception is generated if one of the following conditions exist:

- This is a broadcast message (payload_{BRDCAST}=1);
- The message is intended for this thread (GPIR_{50:63}=payload_{PIRTAG}).

G_DBELL_MC messages are not cumulative. That is, if a G_DBELL_MC message is accepted and the interrupt is pended because MSR_{CE}=0, additional G_DBELL_MC messages that would be accepted are

ignored until the Guest Processor Doorbell Machine Check exception is cleared by taking the interrupt or cleared by executing a *msgclr* with a message type of G_DBELL_MC on the receiving thread.

The temporal relationship between when a G_DBELL_MC message is sent and when it is received in a given thread is not defined.

11.3 Processor Control Instructions

msgsnd and *msgclr* instructions are provided for sending and clearing messages to threads and other devices in the coherence domain. These instructions are privileged.

In the instruction descriptions the statement “this instruction is treated as a *Store*” means that the instruction is treated as a *Store* with respect to the storage access ordering mechanism caused by memory barriers in Section 1.7.1 of Book II.

Message Send

X-form

msgsnd RB

```
msgtype ← GPR(RB)32:36
payload ← GPR(RB)37:63
send_msg_to_coherence_domain(msgtype, payload)
```

msgsnd sends a message to all devices in the coherence domain. The message contains a type and a payload. The message type (*msgtype*) is defined by the contents of RB_{32:36} and the message payload is defined by the contents of RB_{37:63}. Message delivery is reliable and guaranteed. Each device may perform specific actions based on the message type and payload or may ignore messages. Consult the implementation user’s manual for specific actions taken based on message type and payload.

For threads, actions taken on receipt of a message are defined in Section 11.2.1.

For storage access ordering, *msgsnd* is treated as a *Store* with respect to memory barriers.

This instruction is hypervisor privileged.

Special Registers Altered:

None

Message Clear

X-form

msgclr RB

```
msgtype ← GPR(RB)32:36
clear_received_message(msgtype)
```

msgclr clears a message of *msgtype* previously accepted by the thread executing the *msgclr*. *msgtype* is defined by the contents of RB_{32:36}. A message is said to be cleared when a pending exception generated by an accepted message has not yet taken its associated interrupt.

If a pending exception exists for *msgtype* that exception is cleared at the completion of the *msgclr* instruction.

For threads, the types of messages that can be cleared are defined in Section 11.2.1.

This instruction is hypervisor privileged.

Special Registers Altered:

None

Programming Note

Execution of a *msgclr* instruction that clears a pending exception when the associated interrupt is masked because the interrupt enable (MSR_{EE} or MSR_{CE}) is not set to 1 will always clear the pending exception (and thus the interrupt will not occur) if a subsequent instruction causes MSR_{EE} or MSR_{CE} to be set to 1.

Chapter 12. Synchronization Requirements for Context Alterations

Changing the contents of certain System Registers, the contents of TLB entries, or the contents of other system resources that control the context in which a program executes can have the side effect of altering the context in which data addresses and instruction addresses are interpreted, and in which instructions are executed and data accesses are performed. For example, changing certain bits in the MSR has the side effect of changing how instruction addresses are calculated. These side effects need not occur in program order, and therefore may require explicit synchronization by software. (Program order is defined in Book II.)

An instruction that alters the context in which data addresses or instruction addresses are interpreted, or in which instructions are executed or data accesses are performed, is called a *context-altering instruction*. This chapter covers all the context-altering instructions. The software synchronization required for them is shown in Table 13 (for data access) and Table 12 (for instruction fetch and execution).

The notation “CSI” in the tables means any context synchronizing instruction (e.g., *sc*, *isync*, *rfi*, *rfci*, *rfmci*, or *rfdi* [Category: Embedded. Enhanced Debug]). A context synchronizing interrupt (i.e., any interrupt except non-recoverable Machine Check) can be used instead of a context synchronizing instruction. If it is, phrases like “the synchronizing instruction”, below, should be interpreted as meaning the instruction at which the interrupt occurs. If no software synchronization is required before (after) a context-altering instruction, “the synchronizing instruction before (after) the context-altering instruction” should be interpreted as meaning the context-altering instruction itself.

The synchronizing instruction before the context-altering instruction ensures that all instructions up to and including that synchronizing instruction are fetched and executed in the context that existed before the alteration. The synchronizing instruction after the context-altering instruction ensures that all instructions after that synchronizing instruction are fetched and executed in the context established by the alteration. Instructions after the first synchronizing instruction, up to and including the second synchronizing instruction, may be fetched or executed in either context.

If a sequence of instructions contains context-altering instructions and contains no instructions that are affected by any of the context alterations, no software synchronization is required within the sequence.

Programming Note

Sometimes advantage can be taken of the fact that certain events, such as interrupts, and certain instructions that occur naturally in the program, such as an *rfi*, *rfgi* [Category: Embedded.Hypervisor], *rfci*, *rfmci*, or *rfdi* [Category: Embeddd.Enhanced Debug] that returns from an interrupt handler, provide the required synchronization.

No software synchronization is required before or after a context-altering instruction that is also context synchronizing (e.g., *rfi*, etc.) or when altering the MSR in most cases (see the tables). No software synchronization is required before most of the other alterations shown in Table 12, because all instructions preceding the context-altering instruction are fetched and decoded before the context-altering instruction is executed (the hardware must determine whether any of these preceding instructions are context synchronizing).

Unless otherwise stated, the material in this chapter assumes a single-threaded environment.

<i>tlbivax</i>	CSI	CSI, or CSI and sync	1,6
<i>tlbwe</i>	CSI	CSI, or CSI and sync	1,6

Table 13: Synchronization requirements for data access

Notes:

- There are additional software synchronization requirements for this instruction in multi-threaded environments (e.g., it may be necessary to invalidate one or more TLB entries on all threads in the system and to be able to determine that the invalidations have completed and that all side effects of the invalidations have taken effect); it is also necessary to execute a **tlbsync** instruction.
- The alteration must not cause an implicit branch in real address space. Thus the real address of the context-altering instruction and of each subsequent instruction, up to and including the next context synchronizing instruction, must be independent of whether the alteration has taken effect.
- A context synchronizing instruction is required after altering MSR_{ME} to ensure that the alteration takes effect for subsequent Machine Check interrupts, which may not be recoverable and therefore

may not be context synchronizing.

4. The effect of changing MSR_{EE} or MSR_{CE} is immediate.

If an *mtmsr*, *wrtee*, or *wrteei* instruction sets MSR_{EE} to '0', an External Input, DEC or FIT interrupt does not occur after the instruction is executed.

If an *mtmsr*, *wrtee*, or *wrteei* instruction changes MSR_{EE} from '0' to '1' when an External Input, Decrementer, Fixed-Interval Timer, or higher priority enabled exception exists, the corresponding interrupt occurs immediately after the *mtmsr*, *wrtee*, or *wrteei* is executed, and before the next instruction is executed in the program that set MSR_{EE} to '1'.

If an *mtmsr* instruction sets MSR_{CE} to '0', a Critical Input or Watchdog Timer interrupt does not occur after the instruction is executed.

If an *mtmsr* instruction changes MSR_{CE} from '0' to '1' when a Critical Input, Watchdog Timer or higher priority enabled exception exists, the corresponding interrupt occurs immediately after the *mtmsr* is executed, and before the next instruction is executed in the program that set MSR_{CE} to '1'.

5. Synchronization requirements for changing any of the Debug Facility Registers are implementation-dependent.
6. For data accesses, the context synchronizing instruction before the *tlbwe*, *tlbilx* <E.HV>, or *tlbivax* instruction ensures that all storage accesses due to preceding instructions have completed to a point at which they have reported all exceptions they will cause.

The context synchronizing instruction after the *tlbwe*, *tlbilx* <E.HV>, or *tlbivax* ensures that subsequent storage accesses (data and instruction) will use the updated value in the TLB entry(s) being affected. It does not ensure that all storage accesses previously translated by the TLB entry(s) being updated have completed with respect to storage; if these completions must be ensured, the *tlbwe*, *tlbilx* <E.HV>, or *tlbivax* must be followed by a *sync* instruction as well as by a context synchronizing instruction.

Programming Note

The following sequence illustrates why it is necessary, for data accesses, to ensure that all storage accesses due to instructions before the *tlbwe* or *tlbivax* have completed to a point at which they have reported all exceptions they will cause. Assume that valid TLB entries exist for the target storage location when the sequence starts.

- A program issues a load or store to a page.
- The same program executes a *tlbwe* or *tlbivax* that invalidates the corresponding TLB entry.
- The *Load* or *Store* instruction finally executes, and gets a TLB Miss exception.
- The TLB Miss exception is semantically incorrect. In order to prevent it, a context synchronizing instruction must be executed between steps 1 and 2.

7. The elapsed time between the Decrementer reaching zero, or the transition of the selected Time Base bit for the Fixed-Interval Timer or the Watchdog Timer, and the signalling of the Decrementer, Fixed-Interval Timer or the Watchdog Timer exception is not defined.
8. The notation "{*sync*, CSI}" denotes an instruction sequence. Other instructions may be interleaved with this sequence, but these instructions must appear in the order shown.

No software synchronization is required before the *Store* instruction because (a) stores are not performed out-of-order and (b) address translations associated with instructions preceding the *Store* instruction are not performed again after the store has been performed (see Section 5.5). These properties ensure that all address translations associated with instructions preceding the *Store* instruction will be performed using the old contents of the PTE.

The *sync* instruction after the *Store* instruction ensures that all lookups of the Page Table that are performed after the *sync* instruction completes will use the value stored (or a value stored subsequently). The context synchronizing instruction after the *sync* instruction ensures that any address translations associated with instructions following the context synchronizing instruction that were performed using the old contents of the PTE will be discarded, with the result that these address translations will be performed again and, if there is no corresponding entry in any implementation-specific address translation lookaside information, will use the value stored (or a value stored subsequently).

The **sync** instruction also ensures that all storage accesses associated with instructions preceding the **sync** instruction, before the **sync** instruction is executed, will be performed with respect to any thread or mechanism, to the extent required by the associated Memory Coherence Required or Alternate Coherence Mode attributes, before any data accesses caused by instructions following the **sync** instruction are performed with respect to that thread or mechanism.

9. After executing a **mtspr** that sets one of the TLB invalidate all bits in the MMUCSR0 to a 1, software must read MMUCSR0 using a **mtspr** instruction until the corresponding bit is zero and then perform the CSI, or CSI and **sync** as indicated in the “Required After” column.

Appendix A. Implementation-Dependent Instructions

This appendix documents architectural resources that are allocated for specific implementation-sensitive functions which have scope-limited utility. Implementa-

tions may exercise reasonable flexibility in implementing these functions, but that flexibility should be limited to that allowed in this appendix.

A.1 Embedded Cache Initialization [Category: Embedded.Cache Initialization]

Data Cache Invalidate

X-form

dcf CT

0	31	/	CT	///	///	454	/	31
	6	7	11	16	21			

If CT is not supported by the implementation, this instruction designates the primary data cache as the target data cache.

If CT is supported by the implementation, let CT designate either the primary data cache or another level of the data cache hierarchy, as specified in Book II Section 3.2, as the target data cache.

The contents of the target data cache of the thread executing the **dcf** instruction are invalidated.

Software must place a **sync** instruction before the **dcf** to guarantee all previous data storage accesses complete before the **dcf** is performed.

Software must place a **sync** instruction after the **dcf** to guarantee that the **dcf** completes before any subsequent data storage accesses are performed.

This instruction is hypervisor privileged.

Special Registers Altered:

A.2 Embedded Cache Debug Facility [Category: Embedded.Cache Debug]

A.2.1 Embedded Cache Debug Registers

A.2.1.1 Data Cache Debug Tag Register High

The Data Cache Debug Tag Register High (DCDBTRH) is a 32-bit Special Purpose Register. The Data Cache Debug Tag Register High is read using *mfspr* and is set by *dcread*.

Figure 70. Data Cache Debug Tag Register High

Programming Note

An example implementation of DCDBTRH could have the following content and format.

Bit(s)	Description
32:55	Tag Real Address (TRA) Bits 0:23 of the lower 32 bits of the 36-bit real address associated with this cache block
56	Valid (V) The valid indicator for the cache block (1 indicates valid)
57:59	Reserved
60:63	Tag Extended Real Address (TERA) Upper 4 bits of the 36-bit real address associated with this cache block

Implementations may support different content and format based on their cache implementation.

| This register is hypervisor privileged.

A.2.1.2 Data Cache Debug Tag Register Low

The Data Cache Debug Tag Register Low (DCDBTRL) is a 32-bit Special Purpose Register. The Data Cache Debug Tag Register Low is read using *mfspr* and is set by *dcread*.

Figure 71. Data Cache Debug Tag Register Low

Programming Note

An example implementation of DCDBTRL could have the following content and format.

Bit(s)	Description
32:44	Reserved (TRA)
45	U bit parity (UPAR)
46:47	Tag parity (TPAR)
48:51	Data parity (DPAR)
52:55	Modified (dirty) parity (MPAR)
56:59	Dirty Indicators (D) The “dirty” (modified) indicators for each of the four doublewords in the cache block
60	U0 Storage Attribute (U0) The U0 storage attribute for the page associated with this cache block
61	U1 Storage Attribute (U1) The U1 storage attribute for the page associated with this cache block
62	U2 Storage Attribute (U2) The U2 storage attribute for the page associated with this cache block
63	U3 Storage Attribute (U3) The U3 storage attribute for the page associated with this cache block

Implementations may support different content and format based on their cache implementation.

| This register is hypervisor privileged.

A.2.1.3 Instruction Cache Debug Data Register

The Instruction Cache Debug Data Register (ICDBDR) is a read-only 32-bit Special Purpose Register. The Instruction Cache Debug Data Register can be read using *mfspr* and is set by *icread*.

Figure 72. Instruction Cache Debug Data Register

This register is hypervisor privileged.

A.2.1.4 Instruction Cache Debug Tag Register High

The Instruction Cache Debug Tag Register High (ICDBTRH) is a 32-bit Special Purpose Register. The Instruction Cache Debug Tag Register High is read using *mfspr* and is set by *icread*.

Figure 73. Instruction Cache Debug Tag Register High

Programming Note

An example implementation of ICDBTRH could have the following content and format.

Bit(s)	Description
32:55	Tag Effective Address (TEA) Bits 0:23 of the 32-bit effective address associated with this cache block
56	Valid (V) The valid indicator for the cache block (1 indicates valid)
57:58	Tag parity (TPAR)
59	Instruction Data parity (DPA)
60:63	Reserved

Implementations may support different content and format based on their cache implementation.

This register is hypervisor privileged.

A.2.1.5 Instruction Cache Debug Tag Register Low

The Instruction Cache Debug Tag Register Low (ICDBTRL) is a 32-bit Special Purpose Register. The Instruction Cache Debug Tag Register Low is read using *mfspr* and is set by *icread*.

Figure 74. Instruction Cache Debug Tag Register Low

Programming Note

An example implementation of ICDBTRL could have the following content and format.

Bit(s)	Description
32:53	Reserved
54	Translation Space (TS) The address space portion of the virtual address associated with this cache block.
55	Translation ID Disable (TD) TID Disable field for the memory page associated with this cache block
56:63	Translation ID (TID) TID field portion of the virtual address associated with this cache block

Other implementations may support different content and format based on their cache implementation.

This register is hypervisor privileged.

A.2.2 Embedded Cache Debug Instructions

Data Cache Read

X-form

dcread RT,RA,RB

31	RT	RA	RB	486	/
0	6	11	16	21	31

[Alternative Encoding]

31	RT	RA	RB	326	/
0	6	11	16	21	31

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
C ← log2(cache size)
B ← log2(cache block size)
IDX ← EA64-C:63-B
WD ← EA64-B:61
RT0:31 ← undefined
RT32:63 ← (data cache data)[IDX]WD×32:WD×32+31
DCDBTRH ← (data cache tag high)[IDX]
DCDBTRL ← (data cache tag low)[IDX]

```

Let the effective address (EA) be the sum of the contents of register RA, or 0 if RA is equal to 0, and the contents of register RB.

Let C = log₂(cache size in bytes).
Let B = log₂(cache block size in bytes).

EA_{64-C:63-B} selects one of the 2^{C-B} data cache blocks.

EA_{64-B:61} selects one of the data words in the selected data cache block.

The selected word in the selected data cache block is placed into register RT.

The contents of the data cache directory entry associated with the selected data cache block are placed into DCDBTRH and DCDBTRL (see Figure 70 and Figure 71).

dcread requires software to guarantee execution synchronization before subsequent **mfspr** instructions can read the results of the **dcread** instruction into GPRs. In order to guarantee that the **mfspr** instructions obtain the results of the **dcread** instruction, a sequence such as the following must be used:

```

sync          # ensure that all previous
              # cache operations have
              # completed

```

```

dcread    regT,regA,regB# read cache information;

```

```

isync          # ensure dcread completes
              # before attempting to
              # read results

```

```

mfspr    regD,dcdbtrh # move high portion of tag
              # into GPR D

```

```

mfspr    regE,dcdbtrl # move low portion of tag
              # into GPR E

```

This instruction is hypervisor privileged.

Special Registers Altered:
DCDBTRH DCDBTRL

Programming Note

dcread can be used by a debug tool to determine the contents of the data cache, without knowing the specific addresses of the blocks which are currently contained within the cache.

Programming Note

Execution of **dcread** before the data cache has completed all cache operations associated with previously executed instructions (such as block fills and block flushes) is undefined.

Instruction Cache Read**X-form**

icread RA, RB

0	31	///	RA	RB	998	/
	6		11	16	21	31

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + (RB)
C ← log2(cache size)
B ← log2(cache block size)
IDX ← EA64-C:63-B
WD ← EA64-B:61
ICDBDR ← (instruction cache data)[IDX]WD×32:WD×32+31
ICDBTRH ← (instruction cache tag high)[IDX]
ICDBTRL ← (instruction cache tag low)[IDX]

```

Let the effective address (EA) be the sum of the contents of register RA, or 0 if RA is equal to 0, and the contents of register RB.

Let C = log₂(cache size in bytes).
Let B = log₂(cache block size in bytes).

EA_{64-C:63-B} selects one of the 2^{C-B} instruction cache blocks.

EA_{64-B:61} selects one of the data words in the selected instruction cache block.

The selected word in the selected instruction cache block is placed into ICDBDR.

The contents of the instruction cache directory entry associated with the selected cache block are placed into ICDBTRH and ICDBTRL (see Figure 73 and Figure 74).

icread requires software to guarantee execution synchronization before subsequent **mfsprr** instructions can read the results of the **icread** instruction into GPRs. In order to guarantee that the **mfsprr** instructions obtain the results of the **icread** instruction, a sequence such as the following must be used:

```

icread  regA,regB  # read cache information

isync                    # ensure icread completes
                        # before attempting to
                        # read results

mficdbdr  regC      # move instruction
                        # information into GPR C

mficdbtrh regD      # move high portion of
                        # tag into GPR D

mficdbtrl regE      # move low portion of tag
                        # into GPR E

```

This instruction is hypervisor privileged.

Special Registers Altered:

ICDBDR ICDBTRH ICDBTRL

Programming Note

icread can be used by a debug tool to determine the contents of the instruction cache, without knowing the specific addresses of the blocks which are currently contained within the cache.

Appendix B. Assembler Extended Mnemonics

In order to make assembler language programs simpler to write and easier to understand, a set of extended mnemonics and symbols is provided for certain instructions. This appendix defines extended mnemonics and symbols related to instructions defined in Book III.

Assemblers should provide the extended mnemonics and symbols listed here, and may provide others.

B.1 Move To/From Special Purpose Register Mnemonics

This section defines extended mnemonics for the *mtspr* and *mfspir* instructions, including the Special Purpose Registers (SPRs) defined in Book I and certain privileged SPRs, and for the *Move From Time Base* instruction defined in Book II.

The *mtspr* and *mfspir* instructions specify an SPR as a numeric operand; extended mnemonics are provided that represent the SPR in the mnemonic rather than requiring it to be coded as an operand. Similar extended mnemonics are provided for the *Move From*

Time Base instruction, which specifies the portion of the Time Base as a numeric operand.

Note: *mftb* serves as both a basic and an extended mnemonic. The Assembler will recognize an *mftb* mnemonic with two operands as the basic form, and an *mftb* mnemonic with one operand as the extended form. In the extended form the TBR operand is omitted and assumed to be 268 (the value that corresponds to TB).

Table 14: Extended mnemonics for moving to/from an SPR

Special Purpose Register	Move To SPR		Move From SPR	
	Extended	Equivalent to	Extended	Equivalent to
Fixed-Point Exception Register	mtxer Rx	mtspr 1,Rx	mfixer Rx	mfspir Rx,1
Link Register	mtlr Rx	mtspr 8,Rx	mflr Rx	mfspir Rx,8
Count Register	mtctr Rx	mtspr 9,Rx	mfctr Rx	mfspir Rx,9
Decrementer	mtdec Rx	mtspr 22,Rx	mfdec Rx	mfspir Rx,22
Save/Restore Register 0	mtsrr0 Rx	mtspr 26,Rx	mfssr0 Rx	mfspir Rx,26
Save/Restore Register 1	mtsrr1 Rx	mtspr 27,Rx	mfssr1 Rx	mfspir Rx,27
Special Purpose Registers G0 through G3	mtsprg n,Rx	mtspr 272+n,Rx	mfsprg Rx,n	mfspir Rx,272+n
Time Base [Lower]	mttbl Rx	mtspr 284,Rx	mftb Rx	mftb Rx,268 ¹ mfspir Rx,268
Time Base Upper	mttbu Rx	mtspr 285,Rx	mftbu Rx	mftb Rx,269 ¹ mfspir Rx,269
PPR32	mtppr32 Rx	mtspr 898, Rx	mfppr32 Rx	mfspir Rx, 898 ²
Processor Version Register	-	-	mfivr Rx	mfspir Rx,287

¹ The *mftb* instruction is Category: Phased-Out. Assemblers targeting version 2.03 or later of the architecture should generate an *mfspir* instruction for the *mftb* and *mftbu* extended mnemonics; see the corresponding Assembler Note in the *mftb* instruction description (see Section 5.2.1 of Book II).

² Category: Phased-In

Appendix C. Guidelines for 64-bit Implementations in 32-bit Mode and 32-bit Implementations

C.1 Hardware Guidelines

C.1.1 64-bit Specific Instructions

The instructions in the Category: 64-Bit are considered restricted only to 64-bit processing. A 32-bit implementation need not implement the group; likewise, the 32-bit applications will not utilize any of these instructions. All other instructions shall either be supported directly by the implementation, or sufficient infrastructure will be provided to enable software emulation of the instructions. A 64-bit implementation that is executing in 32-bit mode may choose to take an Unimplemented Instruction Exception when these 64-bit specific instructions are executed.

C.1.2 Registers on 32-bit Implementations

The Power ISA provides 32-bit and 64-bit registers. All 32-bit registers shall be supported as defined in the specification except the MSR and EPCR. The MSR shall be supported as defined in the specification except that CM is treated as a reserved bit. EPCR shall be supported as defined in the specification except that ICM and GICM are treated as reserved bits. Only bits 32:63 of the 64-bit registers are required to be implemented in hardware in a 32-bit implementation except for the 64-bit FPRs. Such 64-bit registers include the LR, the CTR, the XER, the 32 GPRs, SRR0, CSRR0, DSRR0 <E.ED>, MCSRR0, MAS2, and GSRR0 <E.HV>.

For additional information, see Section 1.5.2 of Book I.

C.1.3 Addressing on 32-bit Implementations

Only bits 32:63 of the 64-bit instruction and data storage effective addresses need to be calculated and presented to main storage. Given that the only branch and data storage access instructions that are not included in Section C.1.1 are defined to prepend 32 0s to bits 32:63 of the effective address computation, a 32-bit implementation can simply bypass the prepending of

the 32 0s when implementing these instructions. For Branch to Link Register and Branch to Count Register instructions, given the LR and CTR are implemented only as 32-bit registers, only concatenating 2 0s to the right of bits 32:61 of these registers is necessary to form the 32-bit branch target address.

For next sequential instruction address computation, the behavior is the same as for 64-bit implementations in 32-bit mode.

C.1.4 TLB Fields on 32-bit Implementations

32-bit implementations should support bits 32:53 of the Effective Page Number (EPN) field in the TLB. This size provides support for a 32-bit effective address, which Power ISA ABIs may have come to expect to be available. 32-bit implementations may support greater than 32-bit real addresses by supporting more than bits 32:53 of the Real Page Number (RPN) field in the TLB.

C.2 32-bit Software Guidelines

C.2.1 32-bit Instruction Selection

Any software that uses any of the instructions listed in Category: 64-Bit shall be considered 64-bit software, and correct execution cannot be guaranteed on 32-bit implementations. Generally speaking, 32-bit software should avoid using any instruction or instructions that depend on any particular setting of bits 0:31 of any 64-bit application-accessible system register, including General Purpose Registers, for producing the correct 32-bit results. Context switching may or may not preserve the upper 32 bits of application-accessible 64-bit system registers and insertion of arbitrary settings of those upper 32 bits at arbitrary times during the execution of the 32-bit application must not affect the final result.

Appendix D. Example Performance Monitor [Category: Embedded.Performance Monitor]

D.1 Overview

This appendix describes an example of a Performance Monitor facility. It defines an architecture suitable for performance monitoring facilities in the Embedded environment. The architecture itself presents only programming model visible features in conjunction with architecturally defined behavioral features. Much of the selection of events is by necessity implementation-dependent and is not described as part of the architecture; however, this document provides guidelines for some features of a performance monitor implementation that should be followed by all implementations.

The example Performance Monitor facility provides the ability to monitor and count predefined events such as clocks, misses in the instruction cache or data cache, types of instructions decoded, or mispredicted branches. The count of such events can be used to trigger the Performance Monitor exception. While most of the specific events are not architected, the mechanism of controlling data collection is.

The example Performance Monitor facility can be used to do the following:

- Improve system performance by monitoring software execution and then recoding algorithms for more efficiency. For example, memory hierarchy behavior can be monitored and analyzed to optimize task scheduling or data distribution algorithms.
- Characterize performance in environments not easily characterized by benchmarking.
- Help system developers bring up and debug their systems.

D.2 Programming Model

The example Performance Monitor facility defines a set of Performance Monitor Registers (PMRs) that are used to collect and control performance data collection and an interrupt to allow intervention by software. The PMRs provide various controls and access to collected data. They are categorized as follows:

- Counter registers. These registers are used for data collection. The occurrence of selected events are counted here. These registers are named PMC0..15. User and supervisor level access to these registers is through different PMR numbers allowing different access rights.
- Global controls. This register control global settings of the Performance Monitor facility and affect all counters. This register is named PMGC0. User and supervisor level access to these registers is through different PMR numbers allowing different access rights. In addition, a bit in the MSR (MSR_{PMM}) is defined to enable/disable counting.
- Local controls. These registers control settings that apply only to a particular counter. These registers are named PMLCa0..15 and PMLCb0..15. User and supervisor level access to these registers is through different PMR numbers allowing different access rights. Each set of local control registers (PMLCa n and PMLCb n) contains controls that apply to the associated same numbered counter register (e.g. PMLCa0 and PMLCb0 contain controls for PMC0 while PMLCa1 and PMLCb1 contain controls for PMC1).

Assembler Note

The counter registers, global controls, and local controls have alias names which cause the assembler to use different PMR numbers. The names PMC0...15, PMGC0, PMLCa0...15, and PMLCb0...15 cause the assembler to use the supervisor level PMR number, and the names UPMC0...15, UPMGC0, UPMLCa0...15, and UPMLCb0...15 cause the assembler to use the user-level PMR number.

A given implementation may implement fewer counter registers (and their associated control registers) than are architected. Architected counter and counter control registers that are not implemented behave the same as unarchitected Performance Monitor Registers.

PMRs are described in Section D.3.

Software uses the global and local controls to select which events are counted in the counter registers, when such events should be counted, and what action

should be taken when a counter overflows. Software can use the collected information to determine performance attributes of a given segment of code, a process, or the entire software system. PMRs can be read by software using the *mfpmr* instruction and PMRs can be written by using the *mtpmr* instruction. Both instructions are described in Section D.4.

Since counters are defined as 32-bit registers, it is possible for the counting of some events to overflow. A Performance Monitor interrupt is provided that can be programmed to occur in the event of a counter overflow. The Performance Monitor interrupt is described in detail in Section D.2.5 and Section D.2.6.

D.2.1 Event Counting

Event counting can be configured in several different ways. This section describes configurability and specific unconditional counting modes.

D.2.2 Thread Context Configurability

Counting can be enabled if conditions in the thread state match a software-specified condition. Because a software task scheduler may switch a thread's execution among multiple processes and because statistics on only a particular process may be of interest, a facility is provided to mark a process. The Performance Monitor mark bit, MSR_{PMM} , is used for this purpose. System software may set this bit to 1 when a marked process is running. This enables statistics to be gathered only during the execution of the marked process. The states of MSR_{PR} and MSR_{PMM} together define a state that the thread (supervisor or user) and the process (marked or unmarked) may be in at any time. If this state matches an individual state specified by the $PMLCan_{FCS}$, $PMLCan_{FCU}$, $PMLCan_{FCM1}$ and $PMLCan_{FCM0}$ fields in $PMLCan$ (the state for which monitoring is enabled), counting is enabled for $PMCn$.

Each event, on an implementation basis, may count regardless of the value of MSR_{PMM} . The counting behavior of each event should be documented in the User's Manual.

The thread states and the settings of the $PMLCan_{FCS}$, $PMLCan_{FCU}$, $PMLCan_{FCM1}$ and $PMLCan_{FCM0}$ fields in

$PMLCan$ necessary to enable monitoring of each thread state are shown in Figure 75.

Thread State	FCS	FCU	FCM1	FCM0
Marked	0	0	0	1
Not marked	0	0	1	0
Supervisor	0	1	0	0
User	1	0	0	0
Marked and supervisor	0	1	0	1
Marked and user	1	0	0	1
Not marked and supervisor	0	1	1	0
Not mark and user	1	0	1	0
All	0	0	0	0
None	X	X	1	1
None	1	1	X	X

Figure 75. Thread States and PMLCan Bit Settings

Two unconditional counting modes may be specified:

- Counting is unconditionally enabled regardless of the states of MSR_{PMM} and MSR_{PR} . This can be accomplished by setting $PMLCan_{FCS}$, $PMLCan_{FCU}$, $PMLCan_{FCM1}$, and $PMLCan_{FCM0}$ to 0 for each counter control.
- Counting is unconditionally disabled regardless of the states of MSR_{PMM} and MSR_{PR} . This can be accomplished by setting $PMGCO_{FAC}$ to 1 or by setting $PMLCan_{FC}$ to 1 for each counter control. Alternatively, this can be accomplished by setting $PMLCan_{FCM1}$ to 1 and $PMLCan_{FCM0}$ to 1 for each counter control or by setting $PMLCan_{FCS}$ to 1 and $PMLCan_{FCU}$ to 1 for each counter control.

Programming Note

Events may be counted in a fuzzy manner. That is, events may not be counted precisely due to the nature of an implementation. Users of the Performance Monitor facility should be aware that an event may be counted even if it was precisely filtered, though it should not have been. In general such discrepancies are statistically unimportant and users should not assume that counts are explicitly accurate.

D.2.3 Event Selection

Events to count are determined by placing an implementation defined event value into the $PMLCa0..15_{EVENT}$ field. Which events may be programmed into which counter are implementation specific and should be defined in the User's Manual. In general, most events may be programmed into any of the implementation available counters. Programming a counter with an event that is not supported for that counter gives boundedly undefined results.

Programming Note

Event name and event numbers will differ greatly across implementations and software should not expect that events and event names will be consistent.

D.2.4 Thresholds

Thresholds are values that must be exceeded for an event to be counted. Threshold values are programmed in the `PMLCb0..15_THRESHOLD` field. The events which may be thresholded and the units of each event that may be thresholded are implementation-dependent. Programming a threshold value for an event that is not defined to use a threshold gives boundedly undefined results.

D.2.5 Performance Monitor Exception

A Performance Monitor exception occurs when counter overflow detection is enabled and a counter overflows. More specifically, for each counter register n , if `PMGC0PMIE=1` and `PMLCnCE=1` and `PMCNOV=1` and `MSREE = 1`, a Performance Monitor exception is said to exist. The Performance Monitor exception condition will cause a Performance Monitor interrupt if the exception is the highest priority exception.

The Performance Monitor exception is level sensitive and the exception condition may cease to exist if any of the required conditions fail to be met. Thus it is possible for a counter to overflow and continue counting events until `PMCNOV` becomes 0 without taking a Performance Monitor interrupt if `MSREE = 0` during the overflow condition. To avoid this, software should program the counters to freeze if an overflow condition is detected (see Section D.3.4).

D.2.6 Performance Monitor Interrupt

A Performance Monitor interrupt occurs when a Performance Monitor exception exists and no higher priority exception exists. When a Performance Monitor interrupt occurs, `SRR0` and `SRR1` record the current state of the NIA and the MSR and the MSR is set to handle the interrupt. If Interrupt Fixed Offsets [Category: Embedded.Phased-In] are supported, instruction execution resumes at address `IVPR0:51 || 0x260`. Otherwise, instruction execution resumes at address `IVPR0:47 || IVOR3548:59 || 0b0000`.

The Performance Monitor interrupt is precise and asynchronous.

Programming Note

When taking a Performance Monitor interrupt software should clear the overflow condition by reading the counter register and setting the counter register to a non-overflow value since the normal return from the interrupt will set `MSREE` back to 1.

D.3 Performance Monitor Registers**D.3.1 Performance Monitor Global Control Register 0**

The Performance Monitor Global Control Register 0 (`PMGC0`) controls all Performance Monitor counters.

Figure 76. [User] Performance Monitor Global Control Register 0

These bits are interpreted as follows:

Bit	Description
32	Freeze All Counters (FAC) The FAC bit is sticky; that is, once set to 1 it remains set to 1 until it is set to 0 by an <i>mtpmr</i> instruction. <ul style="list-style-type: none"> 0 The PMCs can be incremented (if enabled by other Performance Monitor control fields). 1 The PMCs can not be incremented.
33	Performance Monitor Interrupt Enable (PMIE) <ul style="list-style-type: none"> 0 Performance Monitor interrupts are disabled. 1 Performance Monitor interrupts are enabled and occur when an enabled condition or event occurs. Enabled conditions and events are described in Section D.2.5.
34	Freeze Counters on Enabled Condition or Event (FCECE) Enabled conditions and events are described in Section D.2.5. <ul style="list-style-type: none"> 0 The PMCs can be incremented (if enabled by other Performance Monitor control fields). 1 The PMCs can be incremented (if enabled by other Performance Monitor control fields) only until an enabled condition or event occurs. When an enabled condition or event occurs, <code>PMGC0_{FAC}</code> is set to 1. It is the user's responsibility to set <code>PMGC0_{FAC}</code> to 0.

35:63 Reserved

The UPMGC0 register is an alias to the PMGC0 register for user mode read only access.

D.3.2 Performance Monitor Local Control A Registers

The Performance Monitor Local Control A Registers 0 through 15 (PMLCa0..15) function as event selectors and give local control for the corresponding numbered Performance Monitor counters. PMLCa works with the corresponding numbered PMLCb register.

Figure 77. [User] Performance Monitor Local Control A Registers

PMLCa is set to 0 at reset. These bits are interpreted as follows:

Bit	Description
32	Freeze Counter (FC) 0 The PMC can be incremented (if enabled by other Performance Monitor control fields). 1 The PMC can not be incremented.
33	Freeze Counter in Supervisor State (FCS) 0 The PMC is incremented (if enabled by other Performance Monitor control fields). 1 The PMC can not be incremented if MSR _{PR} is 0.
34	Freeze Counter in User State (FCU) 0 The PMC can be incremented (if enabled by other Performance Monitor control fields). 1 The PMC can not be incremented if MSR _{PR} is 1.
35	Freeze Counter while Mark is Set (FCM1) 0 The PMC can be incremented (if enabled by other Performance Monitor control fields). 1 The PMC can not be incremented if MSR _{PMM} is 1.
36	Freeze Counter while Mark is Cleared (FCM0) 0 The PMC can be incremented (if enabled by other Performance Monitor control fields). 1 The PMC can not be incremented if MSR _{PMM} is 0.
37	Condition Enable (CE)

- 0 Overflow conditions for PMC_n cannot occur (PMC_n cannot cause interrupts, cannot freeze counters)
- 1 Overflow conditions occur when the most-significant-bit of PMC_n is equal to 1.

It is recommended that CE be set to 0 when counter PMC_n is selected for chaining; see Section D.5.1.

38:40	Reserved
41:47	Event Selector (EVENT) Up to 128 events selectable; see Section D.2.3.
48:53	Setting is implementation-dependent.
54:63	Reserved

The UPMLCa0..15 registers are aliases to the PMLCa0..15 registers for user mode read only access.

D.3.3 Performance Monitor Local Control B Registers

The Performance Monitor Local Control B Registers 0 through 15 (PMLCb0..15) specify a threshold value and a multiple to apply to a threshold event selected for the corresponding Performance Monitor counter. Threshold capability is implementation counter dependent. Not all events or all counters of an implementation are guaranteed to support thresholds. PMLCb works with the corresponding numbered PMLCa register.

Figure 78. [User] Performance Monitor Local Control B Register

PMLCb is set to 0 at reset. These bits are interpreted as follows:

Bit	Description
32:52	Reserved
53:55	Threshold Multiple (THRESHMUL) 000 Threshold field is multiplied by 1 (THRESHOLD × 1) 001 Threshold field is multiplied by 2 (THRESHOLD × 2) 010 Threshold field is multiplied by 4 (THRESHOLD × 4) 011 Threshold field is multiplied by 8 (THRESHOLD × 8) 100 Threshold field is multiplied by 16 (THRESHOLD × 16) 101 Threshold field is multiplied by 32 (THRESHOLD × 32) 110 Threshold field is multiplied by 64 (THRESHOLD × 64)

111	Threshold field is multiplied by 128 (THRESHOLD × 128)
56:57	Reserved
58:63	Threshold (THRESHOLD) Only events that exceed the value THRESHOLD multiplied as described by THRESHMUL are counted. Events to which a threshold value applies are implementation-dependent as are the unit (for example duration in cycles) and the granularity with which the threshold value is interpreted.

Programming Note

By varying the threshold value, software can obtain a profile of the event characteristics subject to thresholding. For example, if PMC1 is configured to count cache misses that last longer than the threshold value, software can measure the distribution of cache miss durations for a given program by monitoring the program repeatedly using a different threshold value each time.

The UPMLCb0..15 registers are aliases to the PMLCb0..15 registers for user mode read only access.

D.3.4 Performance Monitor Counter Registers

The Performance Monitor Counter Registers (PMC0..15) are 32-bit counters that can be programmed to generate interrupt signals when they overflow. Each counter is enabled to count up to 128 events.

Figure 79. [User] Performance Monitor Counter Registers

PMCs are set to 0 at reset. These bits are interpreted as follows:

Bit	Description
32	Overflow (OV) 0 Counter has not reached an overflow state. 1 Counter has reached an overflow state.
33:63	Counter Value (CV) Indicates the number of occurrences of the specified event.

The minimum value for a counter is 0 (0x0000_0000) and the maximum value is 4,294,967,295 (0xFFFF_FFFF). A counter can increment up to the maximum value and then wraps to the minimum value. A counter enters the overflow state when the high-order bit is set to 1, which normally occurs only when the counter increments from a value below

2,147,483,648 (0x8000_0000) to a value greater than or equal to 2,147,483,648 (0x8000_0000).

Several different actions may occur when an overflow state is reached, depending on the configuration:

- If PMLCa_nCE is 0, no special actions occur on overflow: the counter continues incrementing, and no exception is signaled.
- If PMLCa_nCE and PMGC0_{FCECE} are 1, all counters are frozen when PMC_n overflows.
- If PMLCa_nCE, PMGC0_{PMIE}, and MSR_{EE} are 1, an exception is signalled when PMC_n reaches overflow. Note that the interrupts are masked by setting MSR_{EE} to 0. An overflow condition may be present while MSR_{EE} is zero, but the interrupt is not taken until MSR_{EE} is set to 1.

If an overflow condition occurs while MSR_{EE} is 0 (the exception is masked), the exception is still signalled once MSR_{EE} is set to 1 if the overflow condition is still present and the configuration has not been changed in the meantime to disable the exception; however, if MSR_{EE} remains 0 until after the counter leaves the overflow state (MSB becomes 0), or if MSR_{EE} remains 0 until after PMLCa_nCE or PMGC0_{PMIE} are set to 0, the exception does not occur.

Programming Note

Loading a PMC with an overflowed value can cause an immediate exception. For example, if PMLCa_nCE, PMGC0_{PMIE}, and MSR_{EE} are all 1, and an *mtpmr* loads an overflowed value into a PMC_n that previously held a non-overflowed value, then an interrupt will be generated before any event counting has occurred.

The following sequence is generally recommended for setting the counter values and configurations.

1. Set PMGC0_{FAC} to 1 to freeze the counters.
2. Perform a series of *mtpmr* operations to initialize counter values and configure the control registers
3. Release the counters by setting PMGC0_{FAC} to 0 with a final *mtpmr*.

D.4 Performance Monitor Instructions

Move From Performance Monitor Register XFX-form

mfpmr RT,PMRN

31	RT	pmrn	334	/
0	6	11	21	31

```
n ← pmrn5:9 || pmrn0:4
if length(PMR(n)) = 64 then
  RT ← PMR(n)
else
  RT ← 320 || PMR(n)32:63
```

Let PMRN denote a Performance Monitor Register number and PMR the set of Performance Monitor Registers.

The contents of the designated Performance Monitor Register are placed into register RT.

The list of defined Performance Monitor Registers and their privilege class is provided in Figure 80.

Execution of this instruction specifying a defined and privileged Performance Monitor Register when MSR_{PR}=1 will result in a Privileged Instruction exception.

Category: Embedded.Hypervisor]

If MSRP_{PMMP} = 1 and MSR_{GS} = 1, execution of this instruction specifying a defined Performance Monitor Register sets RT to 0.

Execution of this instruction specifying an undefined Performance Monitor Register will either result in an Illegal Instruction exception or will produce an undefined value for register RT.

Special Registers Altered:

None

Move To Performance Monitor Register XFX-form

mtpmr PMRN,RS

31	RS	pmrn	462	/
0	6	11	21	31

```
n ← pmrn5:9 || pmrn0:4
if length(PMR(n)) = 64 then
  PMR(n) ← (RS)
else
  PMR(n) ← (RS)32:63
```

Let PMRN denote a Performance Monitor Register number and PMR the set of Performance Monitor Registers.

The contents of the register RS are placed into the designated Performance Monitor Register.

The list of defined Performance Monitor Registers and their privilege class is provided in Figure 80.

Execution of this instruction specifying a defined and privileged Performance Monitor Register when MSR_{PR}=1 will result in a Privileged Instruction exception.

[Category: Embedded.Hypervisor]

If MSRP_{PMMP} = 1 and MSR_{GS} = 1 and MSR_{PR} = 0, execution of this instruction specifying a defined Performance Monitor Register results in a Embedded Hypervisor Privilege exception.

Execution of this instruction specifying an undefined Performance Monitor Register will either result in an Illegal Instruction exception or will perform no operation.

Special Registers Altered:

None

decimal	PMR ¹		Register Name	Privileged		Cat
	pmrn _{5:9}	pmrn _{0:4}		mtpmr	mfpmr	
0-15	00000	0xxxxx	PMC0..15	-	no	E.PM
16-31	00000	1xxxxx	PMC0..15	yes	yes	E.PM

¹ Note that the order of the two 5-bit halves of the PMR number is reversed.						

Figure 80. Embedded.Performance Monitor PMRs

D.5 Performance Monitor Software Usage Notes

D.5.1 Chaining Counters

An implementation may contain events that are used to “chain” counters together to provide a larger range of event counts. This is accomplished by programming the desired event into one counter and programming another counter with an event that occurs when the first counter transitions from 1 to 0 in the most significant bit.

The counter chaining feature can be used to decrease the processing pollution caused by Performance Monitor interrupts, (things like cache contamination, and pipeline effects), by allowing a higher event count than is possible with a single counter. Chaining two counters together effectively adds 32 bits to a counter register where the first counter's carry-out event acts like a carry-out feeding the second counter. By defining the event of interest to be another PMC's overflow generation, the chained counter increments each time the first counter rolls over to zero. Multiple counters may be chained together.

Because the entire chained value cannot be read in a single instruction, an overflow may occur between counter reads, producing an inaccurate value. A sequence like the following is necessary to read the complete chained value when it spans multiple counters and the counters are not frozen. The example shown is for a two-counter case.

```
loop:
  mfpmr    Rx,pmctr1    #load from upper counter
  mfpmr    Ry,pmctr0    #load from lower counter
  mfpmr    Rz,pmctr1    #load from upper counter
  cmp      cr0,0,Rz,Rx  #see if 'old' = 'new'
  bc      4,2,loop
           #loop if carry occurred between reads
```

The comparison and loop are necessary to ensure that a consistent set of values has been obtained. The above sequence is not necessary if the counters are frozen.

D.5.2 Thresholding

Threshold event measurement enables the counting of duration and usage events. Assume an example event, dLFB load miss cycles, requires a threshold value. A dLFB load miss cycles event is counted only when the number of cycles spent recovering from the miss is greater than the threshold. If the event is counted on two counters and each counter has an individual threshold, one execution of a performance monitor program can sample two different threshold values. Measuring code performance with multiple concurrent thresholds expedites code profiling significantly.

This chapter describes computation modes, document conventions, a processor overview, instruction formats, storage addressing, and instruction addressing.

1.1 Overview

Variable Length Encoding (VLE) is a code density optimized re-encoding of much of the instruction set defined by Books I, II, and III-E using both 16-bit and 32-bit instruction formats.

VLE offers more efficient binary representations of applications for the embedded processor spaces where code density plays a major role in affecting overall system cost, and to a somewhat lesser extent, performance.

VLE is a supplement to the instruction set defined by Book I-III and code pages using VLE encoding or non-VLE encoding can be intermingled in a system providing focus on both high performance and code density where most needed.

VLE provides alternative encodings to instructions defined in Books I-III to enable reduced code footprint. This set of alternative encodings is selected on a page basis. A single storage attribute bit selects between

standard instruction encodings and VLE instructions for that page of memory.

Instruction encodings in pages marked as VLE are either 16 or 32 bits long, and are aligned on 16-bit boundaries. Because of this, all instruction pages marked as VLE are required to use Big-Endian byte ordering.

The programming model uses the same register set with both instruction set encodings, although some registers are not accessible by VLE instructions using the 16-bit formats and not all condition register (CR) fields are used by *Conditional Branch* instructions or instructions that access the condition register executing from a VLE instruction page. In addition, immediate fields and displacements differ in size and use, due to the more restrictive encodings imposed by VLE instruction formats.

VLE additional instruction fields are described in Section 1.4.19, "Instruction Fields".

Other than the requirement of Big-Endian byte ordering for instruction pages and the additional storage attribute to identify whether the instruction page corresponds to a VLE section of code, VLE complies with the memory model, register model, timer facilities, debug facilities, and interrupt/exception model defined

in Book I-III and therefore execute in the same environment as non-VLE instructions.

1.2 Documentation Conventions

Book VLE adheres to the documentation conventions defined in Section 1.3 of Book I. Note however that this book defines instructions that apply to the User Instruction Set Architecture, the Virtual Environment Architecture, and the Operating Environment Architecture.

1.2.1 Description of Instruction Operation

The RTL (register transfer language) descriptions in Book VLE conform to the conventions described in Section 1.3.4 of Book I.

1.3 Instruction Mnemonics and Operands

The description of each instruction includes the mnemonic and a formatted list of operands. VLE instruction semantics are either identical or similar to those of other instructions in the architecture. Where the semantics, side-effects, and binary encodings are identical, the standard mnemonics and formats are used. Such unchanged instructions are listed and appropriately referenced, but the instruction definitions are not replicated in this book. Where the semantics are similar but the binary encodings differ, the standard mnemonic is typically preceded with an *e_* to denote a VLE instruction. To distinguish between similar instructions available in both 16- and 32-bit forms under VLE and standard instructions, VLE instructions encoded with 16 bits have an *se_* prefix. The following are examples:

```
stwx RS,RA,RB    // standard Book I instruction
e_stw RS,D(RA)   // 32-bit VLE instruction
se_stw RZ,SD4(RX) // 16-bit VLE instruction
```

1.4 VLE Instruction Formats

All VLE instructions to be executed are either two or four bytes long and are halfword-aligned in storage. Thus, whenever instruction addresses are presented to the processor (as in *Branch* instructions), the low-order bit is treated as 0. Similarly, whenever the processor generates an instruction address, the low-order bit is zero.

The format diagrams given below show horizontally all valid combinations of instruction fields. Only those formats that are unique to VLE-defined instructions are included here. Instruction forms that are available in VLE or non-VLE mode are described in Section 1.6 of Book I and are not repeated here.

In some cases an instruction field must contain a particular value. If a field that must contain a particular value does not contain that value, the instruction form is invalid and the results are as described for invalid instruction forms in Book I.

VLE instructions use split field notation as defined in Section 1.6 of Book I.

1.4.19 Instruction Fields

VLE uses instruction fields defined in Section 1.6.28 of Book I as well as VLE-defined instruction fields defined below.

ARX (12:15)

Field used to specify an “alternate” General Purpose Register in the range R8:R23 to be used as a destination.

ARY (8:11)

Field used to specify an “alternate” General Purpose Register in the range R8:R23 to be used as a source.

BD8 (8:15), BD15 (16:30), BD24 (7:30)

Immediate field specifying a signed two's complement branch displacement which is concatenated on the right with 0b0 and sign-extended to 64 bits.

BD15. (Used by 32-bit branch conditional class instructions) A 15-bit signed displacement that is sign-extended and shifted left one bit (concatenated with 0b0) and then added to the current instruction address to form the branch target address.

BD24. (Used by 32-bit branch class instructions) A 24-bit signed displacement that is sign-extended and shifted left one bit (concatenated with 0b0) and then added to the current instruction address to form the branch target address.

BD8. (Used by 16-bit branch and branch conditional class instructions) An 8-bit signed displacement that is sign-extended and shifted left one bit (concatenated with 0b0) and then added to the current instruction address to form the branch target address.

BI16 (6:7), BI32 (12:15)

Field used to specify one of the Condition Register fields to be used as a condition of a Branch Conditional instruction.

BO16 (5), BO32 (10:11)

Field used to specify whether to branch if the condition is true, false, or to decrement the Count Register and branch if the Count Register is not zero in a Branch Conditional instruction.

BF32 (9:10)

Field used to specify one of the Condition Register fields to be used as a target of a compare instruction.

D8 (24:31)

The D8 field is a 8-bit signed displacement which is sign-extended to 64 bits.

ELEV (16:20)

Field used by the *e_sc* instruction.

F (21)

Fill value used to fill the remaining 56 bits of a scaled-immediate 8 value.

LI20 (17:20 || 11:15 || 21:31)

A 20-bit signed immediate value which is sign-extended to 64 bits for the *e_li* instruction.

LK (7, 15, 31)

LINK bit.

0 Do not set the Link Register.

1 Set the Link Register. The sum of the value 2 or 4 and the address of the *Branch* instruction is placed into the Link Register.

OIM5 (7:11)

Offset Immediate field used to specify a 5-bit unsigned fixed-point value in the range [1:32] encoded as [0:31]. Thus the binary encoding of 0b00000 represents an immediate value of 1, 0b00001 represents an immediate value of 2, and so on.

OPCD (0:3, 0:4, 0:5, 0:9, 0:14, 0:15)

Primary opcode field.

Rc (6, 7, 20, 31)

RECORD bit.

0 Do not alter the Condition Register.

1 Set Condition Register Field 0.

RX (12:15)

Field used to specify a General Purpose Register in the ranges R0:R7 or R24:R31 to be used as a source or as a destination. R0 is encoded as 0b0000, R1 as 0b0001, etc. R24 is encoded as 0b1000, R25 as 0b1001, etc.

RY (8:11)

Field used to specify a General Purpose Register in the ranges R0:R7 or R24:R31 to be used as a source. R0 is encoded as 0b0000, R1 as 0b0001, etc. R24 is encoded as 0b1000, R25 as 0b1001, etc.

RZ (8:11)

Field used to specify a General Purpose Register in the ranges R0:R7 or R24:R31 to be used as a source or as a destination for load/store data. R0 is encoded as 0b0000, R1 as 0b0001, etc. R24 is encoded as 0b1000, R25 as 0b1001, etc.

SCL (22:23)

Field used to specify a scale amount in *Immediate* instructions using the SCI8-form. Scaling involves left shifting by 0, 8, 16, or 24 bits.

SD4 (4:7)

Used by 16-bit load and store class instructions. The SD4 field is a 4-bit unsigned immediate value zero-extended to 64 bits, shifted left according to the size of the operation, and then added to the base register to form a 64-bit EA. For byte operations, no shift is performed. For half-word operations, the immediate is shifted left one bit (concatenated with 0b0). For word operations, the immediate is shifted left two bits (concatenated with 0b00).

SI (6:10 || 21:31, 11:15 || 21:31)
A 16-bit signed immediate value sign-extended to 64 bits and used as one operand of the instruction.

UI (6:10 || 21:31, 11:15 || 21:31)

A 16-bit unsigned immediate value zero-extended to 64 bits or padded with 16 zeros and used as one operand of the instruction. The instruction encoding differs between the I16A and I16L instruction formats as shown in Section 1.4.13 and Section 1.4.14.

UI5 (7:11)

Immediate field used to specify a 5-bit unsigned fixed-point value.

UI7 (5:11)

Immediate field used to specify a 7-bit unsigned fixed-point value.

UI8 (24:31)

Immediate field used to specify an 8-bit unsigned fixed-point value.

XO (6, 6:7, 6:10, 6:11, 16, 16:19, 16:20, 16:23, 31)

Extended opcode field.

Assembler Note

For scaled immediate instructions using the SCI8-form, the instruction assembly syntax requires a single immediate value, *sci8*, that the assembler will synthesize into the appropriate F, SCL, and UI8 fields. The F, SCL, and UI8 fields must be able to be formed correctly from the given *sci8* value or the assembler will flag the assembly instruction as an error.

Chapter 2. VLE Storage Addressing

2.1 Data Storage Addressing	2.2.2 VLE Exception Syndrome
Modes 1129	Bits 1130
2.2 Instruction Storage Addressing	
Modes 1130	
2.2.1 Misaligned, Mismatched, and Byte Ordering Instruction Storage	
Exceptions 1130	

A program references memory using the effective address (EA) computed by the processor when it executes a *Storage Access* or *Branch* instruction (or certain other instructions described in Book II and Book III-E), or when it fetches the next sequential instruction.

2.1 Data Storage Addressing Modes

Table 1 lists data storage addressing modes supported by the VLE category.

Mode	Form	Description
Base+16-bit displacement (32-bit instruction format)	D-form	The 16-bit D field is sign-extended and added to the contents of the GPR designated by RA or to zero if RA = 0 to produce the EA.
Base+8-bit displacement (32-bit instruction format)	D8-form	The 8-bit D8 field is sign-extended and added to the contents of the GPR designated by RA or to zero if RA = 0 to produce the EA.
Base+scaled 4-bit displacement (16-bit instruction format)	SD4-form	The 4-bit SD4 field zero-extended, scaled (shifted left) according to the size of the operand, and added to the contents of the GPR designated by RX to produce the EA. (Note that RX = 0 is not a special case.)
Base+Index (32-bit instruction format)	X-form	The GPR contents designated by RB are added to the GPR contents designated by RA or to zero if RA = 0 to produce the EA.

2.2 Instruction Storage Addressing Modes

Table 2 lists instruction storage addressing modes supported by the VLE category.

Mode	Description
Taken BD24-form Branch instructions (32-bit instruction format)	The 24-bit BD24 field is concatenated on the right with 0b0, sign-extended, and then added to the address of the branch instruction.
Taken B15-form Branch instructions (32-bit instruction format)	The 15-bit BD15 field is concatenated on the right with 0b0, sign-extended, and then added to the address of the branch instruction to form the EA of the next instruction.
Take BD8-form Branch instructions (16-bit instruction format)	The 8-bit BD8 field is concatenated on the right with 0b0, sign-extended, and then added to the address of the branch instruction to form the EA of the next instruction.
Sequential instruction fetching (or non-taken branch instructions)	The value 4 [2] is added to the address of the current 32-bit [16-bit] instruction to form the EA of the next instruction. If the address of the current instruction is 0xFFFF_FFFF_FFFF_FFFC [0xFFFF_FFFF_FFFF_FFFE] in 64-bit mode or 0xFFFF_FFFC [0xFFFF_FFFE] in 32-bit mode, the address of the next sequential instruction is undefined.
Any Branch instruction with LK = 1 (32-bit instruction format)	The value 4 is added to the address of the current branch instruction and the result is placed into the LR. If the address of the current instruction is 0xFFFF_FFFF_FFFF_FFFC in 64-bit mode or 0xFFFF_FFFC in 32-bit mode, the result placed into the LR is undefined.
Branch <i>se_bl</i> , <i>se_btrl</i> , <i>se_bctrl</i> instructions (16-bit instruction format)	The value 2 is added to the address of the current branch instruction and the result is placed into the LR. If the address of the current instruction is 0xFFFF_FFFF_FFFF_FFFE in 64-bit mode or 0xFFFF_FFFE in 32-bit mode, the result placed into the LR is undefined.

2.2.1 Misaligned, Mismatched, and Byte Ordering Instruction Storage Exceptions

A *Misaligned Instruction Storage Exception* occurs when an implementation which supports VLE attempts to execute an instruction that is not 32-bit aligned and the VLE storage attribute is not set for the page that corresponds to the effective address of the instruction. The attempted execution can be the result of a *Branch* instruction which has bit 62 of the target address set to 1 or the result of an *rfl*, *se_rfl*, *rflci*, *se_rflci*, *rfdi*, *se_rfdi*, *rfgi*, *se_rfgi*, *rfmci*, or *se_rfmci* instruction which has bit 62 set in SRR0, SRR0, CSRR0, CSRR0, DSRR0, DSRR0, GSRR0, GSRR0, MCSRR0, or MCSRR0 respectively. If a Misaligned Instruction Storage Exception is detected and no higher priority exception exists, an Instruction Storage Interrupt will occur setting SRR0(GSRR0) to the misaligned address for which execution was attempted.

A *Mismatched Instruction Storage Exception* occurs when an implementation which supports VLE attempts to execute an instruction that crosses a page boundary for which the first page has the VLE storage attribute set to 1 and the second page has the VLE storage

attribute bit set to 0. If a Mismatched Instruction Storage Exception is detected and no higher priority exception exists, an Instruction Storage Interrupt will occur setting SRR0(GSRR0) to the misaligned address for which execution was attempted.

A *Byte Ordering Instruction Storage Exception* occurs when an implementation which supports VLE attempts to execute an instruction that has the VLE storage attribute set to 1 and the E (Endian) storage attribute set to 1 for the page that corresponds to the effective address of the instruction. If a Byte Ordering Instruction Storage Exception is detected and no higher priority exception exists, an Instruction Storage Interrupt will occur setting SRR0(GSRR0) to the address for which execution was attempted.

2.2.2 VLE Exception Syndrome Bits

Two bits in the Exception Syndrome Register (ESR) (see Section 7.2.13 of Book III-E) are provided to facilitate VLE exception handling, VLEMI and MIF.

ESR(GESR)_{VLEMI} is set when an exception and subsequent interrupt is caused by the execution or attempted

execution of an instruction that resides in memory with the VLE storage attribute set.

- ESR(GESR)_{MIF} is set when an Instruction Storage Interrupt is caused by a Misaligned Instruction Storage Exception or when an Instruction TLB Error Interrupt was caused by a TLB miss on the second half of a misaligned 32-bit instruction.
- ESR(GESR)_{BO} is set when an Instruction Storage Interrupt is caused by a Mismatched Instruction Storage Exception or a Byte Ordering Instruction Storage Exception.

Programming Note

When an Instruction TLB Error Interrupt occurs as the result of a Instruction TLB miss on the second half of a 32-bit VLE instruction that is aligned to only 16-bits, SRR0 will point to the first half of the instruction and ESR_{MIF} will be set to 1. Any other status posted as a result of the TLB miss (such as MAS register updates described in Chapter 6 of Book III-E) will reflect the page corresponding to the second half of the instruction which caused the Instruction TLB miss.

Chapter 3. VLE Compatibility with Books I–III

3.1 Overview	1133	3.2.2 MMU Extensions	1133
3.2 VLE Processor and Storage Control Extensions	1133	3.3 VLE Limitations	1134
3.2.1 Instruction Extensions	1133		

This chapter addresses the relationship between VLE and Books I–III.

3.1 Overview

Category VLE uses the same semantics as Books I–III. Due to the limited instruction encoding formats, VLE instructions typically support reduced immediate fields and displacements, and not all operations defined by Books I–III are encoded in category VLE. The basic philosophy is to capture all useful operations, with most frequent operations given priority. Immediate fields and displacements are provided to cover the majority of ranges encountered in embedded control code. Instructions are encoded in either a 16- or 32-bit format, and these may be freely intermixed.

VLE instructions cannot access floating-point registers (FPRs). VLE instructions use GPRs and SPRs with the following limitations:

- VLE instructions using the 16-bit formats are limited to addressing GPR0–GPR7, and GPR24–GPR31 in most instructions. Move instructions are provided to transfer register contents between these registers and GPR8–GPR23.
- VLE compare and bit test instructions using the 16-bit formats implicitly set their results in CR0.

VLE instruction encodings are generally different than instructions defined by Books I–III, except that most instructions falling within primary opcode 31 are encoded identically and have identical semantics unless they affect or access a resource not supported by category VLE.

3.2 VLE Processor and Storage Control Extensions

This section describes additional functionality to support category VLE.

3.2.1 Instruction Extensions

This section describes extensions to support VLE operations. Because instructions may reside on a half-word boundary, bit 62 is not masked by instructions that read an instruction address from a register, such as the LR, CTR, or a save/restore register 0, that holds an instruction address:

The instruction set defined by Books I–III is modified to support halfword instruction addressing, as follows:

- For *Return From Interrupt* instructions, such as *rfi*, *rfdi*, *rfdi*, *rfdi*, and *rfmci* no longer mask bit 62 of the respective save/restore register 0. The destination address is $SRR0_{0:62} \parallel 0b0$, $CSRR0_{0:62} \parallel 0b0$, $DSRR0_{0:62} \parallel 0b0$, $GSRR0_{0:62} \parallel 0b0$, and $MCSRR0_{0:62} \parallel 0b0$, respectively.
- For *bclr*, *bclrl*, *bcctr*, and *bcctrl* no longer mask bit 62 of the LR or CTR. The destination address is $LR_{0:62} \parallel 0b0$ or $CTR_{0:62} \parallel 0b0$.

3.2.2 MMU Extensions

VLE operation is indicated by the VLE storage attribute. When the VLE storage attribute for a page is set to 1, instruction fetches from that page are decoded and processed as VLE instructions. See Section 6.8.3 of Book III-E.

When instructions are executing from a page that has the VLE storage attribute set to 1, the processor is said to be in *VLE mode*.

3.3 VLE Limitations

VLE instruction fetches are valid only when performed in a Big-Endian mode. Attempting to fetch an instruction in a Little-Endian mode from a page with the VLE storage attribute set causes an Instruction Storage Byte-ordering exception.

Support for concurrent modification and execution of VLE instructions is implementation-dependent.

Chapter 4. Branch Operation Instructions

4.1 Branch Facility Registers	1135	4.1.2 Link Register (LR)	1136
4.1.1 Condition Register (CR)	1135	4.1.3 Count Register (CTR)	1136
4.1.1.1 Condition Register Setting for Compare Instructions	1136	4.2 Branch Instructions	1137
4.1.1.2 Condition Register Setting for the Bit Test Instruction.	1136	4.3 System Linkage Instructions	1140
		4.4 Condition Register Instructions	1144

This section defines *Branch* instructions that can be executed when a processor is in VLE mode and the registers that support them.

4.1 Branch Facility Registers

The registers that support branch operations are:

- Section 4.1.1, “Condition Register (CR)”
- Section 4.1.2, “Link Register (LR)”
- Section 4.1.3, “Count Register (CTR)”

4.1.1 Condition Register (CR)

The Condition Register (CR) is a 32-bit register which reflects the result of certain operations, and provides a mechanism for testing (and branching). The CR is more fully defined in Book I.

Category VLE uses the entire CR, but some comparison operations and all *Branch* instructions are limited to using CR0–CR3. The full Book I condition register field and logical operations are provided however.

Figure 18. Condition Register

The bits in the Condition Register are grouped into eight 4-bit fields, CR Field 0 (CR0) ... CR Field 7 (CR7), which are set by VLE defined instructions in one of the following ways.

- Specified fields of the condition register can be set by a move to the CR from a GPR (*mtcrf*, *mtocrf*).
- A specified CR field can be set by a move to the CR from another CR field (*e_mcrf*) or from XER_{32:35} (*mcrxr*).
- CR field 0 can be set as the implicit result of a fixed-point instruction.

- A specified CR field can be set as the result of a fixed-point compare instruction.
- CR field 0 can be set as the result of a fixed-point bit test instruction.

Other instructions from implemented categories may also set bits in the CR in the same manner that they would when not in VLE mode.

Instructions are provided to perform logical operations on individual CR bits and to test individual CR bits.

For all fixed-point instructions in which the Rc bit is defined and set, and for *e_add2i.*, *e_and2i.*, and *e_and2is.*, the first three bits of CR field 0 (CR_{32:34}) are set by signed comparison of the result to zero, and the fourth bit of CR field 0 (CR₃₅) is copied from the final state of XER₅₀. “Result” here refers to the entire 64-bit value placed into the target register in 64-bit mode, and to bits 32:63 of the value placed into the target register in 32-bit mode.

```

if (64-bit mode)
  then M ← 0
  else M ← 32
if (target_register)M:63 < 0 then c ← 0b100
else if (target_register)M:63 > 0 then c ← 0b010
else c ← 0b001
CR0 ← c || XER50

```

If any portion of the result is undefined, the value placed into the first three bits of CR field 0 is undefined.

The bits of CR field 0 are interpreted as shown below.

CR Bit	Description
32	Negative (LT) The result is negative.
33	Positive (GT) The result is positive.
34	Zero (EQ) The result is 0.

- 35 **Summary overflow (SO)**
This is a copy of the contents of XER_{SO} at the completion of the instruction.

4.1.1.1 Condition Register Setting for Compare Instructions

For compare instructions, a CR field specified by the BF operand for the *e_cmph*, *e_cmphl*, *e_cmpi*, and *e_cmpli* instructions, or CR0 for the *se_cmpl*, *e_cmp16i*, *e_cmph16i*, *e_cmphl16i*, *e_cmpl16i*, *se_cmp*, *se_cmph*, *se_cmphl*, *se_cmpi*, and *se_cmpli* instructions, is set to reflect the result of the comparison. The CR field bits are interpreted as shown below. A complete description of how the bits are set is given in the instruction descriptions and Section 5.6, “Fixed-Point Compare and Bit Test Instructions”.

Condition register bits settings for compare instructions are interpreted as follows. (Note: *e_cmpi*, and *e_cmpli* instructions have a BF32 field instead of BF field; for these instructions, BF32 should be substituted for BF in the list below.)

CR Bit Description

4×BF + 32

Less Than (LT)

For signed fixed-point compare, (RA) or (RX) < sci8, SI, (RB), or (RY).

For unsigned fixed-point compare, (RA) or (RX) <^u sci8, UI, UI5, (RB), or (RY).

4×BF + 33

Greater Than (GT)

For signed fixed-point compare, (RA) or (RX) > sci8, SI, (RB), or (RY).

For unsigned fixed-point compare, (RA) or (RX) >^u sci8, UI, UI5, (RB), or (RY).

4×BF + 34

Equal (EQ)

For fixed-point compare, (RA) or (RX) = sci8, UI, UI5, SI, (RB), or (RY).

4×BF + 35

Summary Overflow (SO)

For fixed-point compare, this is a copy of the contents of XER_{SO} at the completion of the instruction.

4.1.1.2 Condition Register Setting for the Bit Test Instruction

The Bit Test Immediate instruction, *se_btsti*, also sets CR field 0. See the instruction description and also Section 5.6, “Fixed-Point Compare and Bit Test Instructions”.

4.1.2 Link Register (LR)

VLE instructions use the Link Register (LR) as defined in Book I, although category VLE defines a subset of all variants of Book I conditional branches involving the LR.

4.1.3 Count Register (CTR)

VLE instructions use the Count Register (CTR) as defined in Book I, although category VLE defines a subset of the variants of Book I conditional branches involving the CTR.

4.2 Branch Instructions

The sequence of instruction execution can be changed by the branch instructions. Because VLE instructions must be aligned on half-word boundaries, the low-order bit of the generated branch target address is forced to 0 by the processor in performing the branch.

The branch instructions compute the EA of the target in one of the following ways, as described in Section 2.2, “Instruction Storage Addressing Modes”

1. Adding a displacement to the address of the branch instruction.
2. Using the address contained in the LR (Branch to Link Register [and Link]).
3. Using the address contained in the CTR (Branch to Count Register [and Link]).

Branching can be conditional or unconditional, and the return address can optionally be provided. If the return address is to be provided ($LK = 1$), the EA of the instruction following the branch instruction is placed into the LR after the branch target address has been computed; this is done regardless of whether the branch is taken.

In branch conditional instructions, the BI32 or BI16 instruction field specifies the CR bit to be tested. For 32-bit instructions using BI32, $CR_{32:47}$ (corresponding to bits in CR0:CR3) may be specified. For 16-bit instructions using BI16, only $CR_{32:35}$ (bits within CR0) may be specified.

In branch conditional instructions, the BO32 or BO16 field specifies the conditions under which the branch is taken and how the branch is affected by or affects the CR and CTR. Note that VLE instructions also have different encodings for the BO32 and BO16 fields than in Book I’s BO field.

If the BO32 field specifies that the CTR is to be decremented, in 64-bit mode $CTR_{0:63}$ are decremented, and in 32-bit mode $CTR_{32:63}$ are decremented. If BO16 or BO32 specifies a condition that must be TRUE or FALSE, that condition is obtained from the contents of $CR_{BI32+32}$ or $CR_{BI16+32}$. (Note that CR bits are numbered 32:63. BI32 or BI16 refers to the condition register bit field in the branch instruction encoding. For example, specifying $BI32 = 2$ refers to CR_{34} .)

For Figure 19 let $M = 0$ in 64-bit mode and $M = 32$ in 32-bit mode.

Encodings for the BO32 field for VLE are shown in Figure 19.

BO32	Description
00	Branch if the condition is false.
01	Branch if the condition is true.
10	Decrement $CTR_{M:63}$, then branch if the decremented $CTR_{M:63} \neq 0$
11	Decrement $CTR_{M:63}$, then branch if the decremented $CTR_{M:63} = 0$.

Figure 19. BO32 field encodings

Encodings for the BO16 field for VLE are shown in Figure 20.

BO16	Description
0	Branch if the condition is false.
1	Branch if the condition is true.

Figure 20. BO16 field encodings

Branch to Count Register [and Link] C-form

se_bctr (LK=0)
se_bctrl (LK=1)

$NIA \leftarrow_{iea} CTR_{0:62} \parallel 0b0$
if LK then $LR \leftarrow_{iea} CIA + 2$

The branch target address is $CTR_{0:62} \parallel 0b0$ with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the *Branch* instruction is placed into the Link Register.

Special Registers Altered:
LR (if LK=1)

Branch to Link Register [and Link]C-form

se_blr (LK=0)
se_blrl (LK=1)

$NIA \leftarrow_{iea} LR_{0:62} \parallel 0b0$
if LK then $LR \leftarrow_{iea} CIA + 2$

The branch target address is $LR_{0:62} \parallel 0b0$ with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the *Branch* instruction is placed into the Link Register.

Special Registers Altered:
LR (if LK=1)

4.3 System Linkage Instructions

The *System Linkage* instructions enable the program to call upon the system to perform a service and provide a means by which the system can return from performing a service or from processing an interrupt. System Linkage instructions defined by the VLE category are identical in semantics to *System Linkage* instructions defined

in Book I and Book III-E with the exception of the LEV field, but are encoded differently.

se_sc provides the same functionality as the Book I (and Book III-E) instruction **sc** without the LEV field. **se_rfi**, **se_rfci**, **se_rfdi**, and **se_rfmci** provide the same functionality as the Book III-E instructions **rfi**, **rfci**, **rfdi**, and **rfmci** respectively.

System Call

C-form,ESC-form

se_sc

e_sc ELEV [Category:Embedded.Hypervisor]

```

lev = ELEV
if 'se_sc' then
  lev ← 0
  rr0 ←iea CIA + 2
else if 'e_sc' then
  lev ← ELEV
  rr0 ←iea CIA + 4
if lev = 0 then
  if MSRGS = 1 then
    GSRR0 ←iea rr0
    GSRR1 ← MSR
    if IVORs supported then
      NIA ← GIVPR0:47 ||
        GIVOR848:59 || 0b0000
    else
      NIA ← GIVPR0:51 || 0x120
    MSR ← new_value (see below)
  else
    SRR0 ←iea rr0
    SRR1 ← MSR
    if IVORs supported then
      NIA ← IVPR0:47 ||
        IVOR848:59 || 0b0000
    else
      NIA ← IVPR0:51 || 0x120
    MSR ← new_value (see below)
else if ELEV = 1 then
  SRR0 ←iea CIA + 4
  SRR1 ← MSR
  if IVORs supported then
    NIA ← IVPR0:47 || IVOR4048:59 || 0b0000
  else
    NIA ← IVPR0:51 || 0x300
  MSR ← new_value (see below)

```

If category E.HV is not implemented, the *System Call* instruction behaves as if MSR_{GS} = 0 and ELEV = 0.

If MSR_{GS} = 0 or if ELEV = 1, the effective address of the instruction following the *System Call* instruction is placed into SRR0 and the contents of the MSR are copied into SRR1. Otherwise, the effective address of the instruction following the *System Call* instruction is placed into GSRR0 and the contents of the MSR are copied into GSRR1. ELEV values greater than 1 are reserved. Bits 0:3 of the ELEV field (instruction bits 16:19) are treated as a reserved field.

If ELEV=0, a System Call interrupt is generated. If ELEV=1, an Embedded Hypervisor System Call interrupt is generated. The interrupt causes the MSR to be set as described in Section 7.6.10 and Section 7.6.27 of Book III-E.

If ELEV=0 or **se_sc** is executed, and the processor is in guest state, instruction execution resumes at the address given by one of the following.

- GIVPR_{0:47} || GIVOR_{848:59} || 0b0000 if IVORs [Category:Embedded.Phased-Out] are supported.
- GIVPR_{0:51} || 0x120 if Interrupt Fixed Offsets [Category:Embedded.Phased-In] are supported.

If ELEV=0 or **se_sc** is executed, and the processor is in hypervisor state, instruction execution resumes at the address given by one of the following.

- IVPR_{0:47} || IVOR_{848:59} || 0b0000 if IVORs [Category:Embedded.Phased-Out] are supported.
- IVPR_{0:51} || 0x120 if Interrupt Fixed Offsets [Category:Embedded.Phased-In] are supported.

If ELEV=1, the interrupt causes instruction execution to resume at the address given by one of the following.

- GIVPR_{0:47} || GIVOR_{4048:59} || 0b0000 if IVORs [Category:Embedded.Phased-Out] are supported.
- GIVPR_{0:51} || 0x300 if Interrupt Fixed Offsets [Category:Embedded.Phased-In] are supported.

This instruction is context synchronizing.

Special Registers Altered:

SRR0 GSRR0 SRR1 GSRR1 MSR

Programming Note

e_sc serves as both a basic and an extended mnemonic. The Assembler will recognize an **e_sc** mnemonic with one operand as the basic form, and an **e_sc** mnemonic with no operand as the extended form. In the extended form, the ELEV operand is omitted and assumed to be 0.

Illegal

se_illegal

se_illegal is used to request an Illegal Instruction exception.

The behavior is the same as if an illegal instruction was executed.

This instruction is context synchronizing.

Special Registers Altered:

SRR0 SRR1 MSR ESR

C-form**Return From Machine Check Interrupt C-form**

se_rfmci

MSR ← MCSRR1

NIA ←_{iea} MCSRR0_{0:62} || 0b0

The **se_rfmci** instruction is used to return from a machine check class interrupt, or as a means of establishing a new context and synchronizing on that new context simultaneously.

The contents of MCSRR1 are placed into the MSR. If the new MSR value does not enable any pending exceptions, then the next instruction is fetched, under control of the new MSR value, from the address MCSRR0_{0:62}||0b0. If the new MSR value enables one or more pending exceptions, the interrupt associated with the highest priority pending exception is generated; in this case the values placed into the save/restore registers by the interrupt processing mechanism (see Chapter 7 of Book III-E) is the address and MSR value of the instruction that would have been executed next had the interrupt not occurred (that is, the address in MCSRR0 at the time of the execution of the **se_rfmci**).

This instruction is privileged and context synchronizing.

Special Registers Altered:

MSR

Return From Critical Interrupt C-form

se_rfcf

MSR \leftarrow CSRR1
 NIA \leftarrow _{iea} CSRR0_{0:62} || 0b0

The **se_rfcf** instruction is used to return from a critical class interrupt, or as a means of establishing a new context and synchronizing on that new context simultaneously.

The contents of CSRR1 are placed into the MSR. If the new MSR value does not enable any pending exceptions, then the next instruction is fetched, under control of the new MSR value, from the address CSRR0_{0:62}||0b0. If the new MSR value enables one or more pending exceptions, the interrupt associated with the highest priority pending exception is generated; in this case the values placed into the save/restore registers by the interrupt processing mechanism (see Chapter 7 of Book III-E) is the address and MSR value of the instruction that would have been executed next had the interrupt not occurred (that is, the address in CSRR0 at the time of the execution of the **se_rfcf**).

This instruction is privileged and context synchronizing.

Special Registers Altered:
MSR

Return From Interrupt C-form

se_rfi

MSR \leftarrow SRR1
 NIA \leftarrow _{iea} SRR0_{0:62} || 0b0

The **se_rfi** instruction is used to return from a non-critical class interrupt, or as a means of establishing a new context and synchronizing on that new context simultaneously.

The contents of SRR1 are placed into the MSR. If the new MSR value does not enable any pending exceptions, then the next instruction is fetched under control of the new MSR value from the address SRR0_{0:62}||0b0. If the new MSR value enables one or more pending exceptions, the interrupt associated with the highest priority pending exception is generated; in this case the values placed into the save/restore registers by the interrupt processing mechanism (see Chapter 7 of Book III-E) is the address and MSR value of the instruction that would have been executed next had the interrupt not occurred (that is, the address in SRR0 at the time of the execution of the **se_rfi**).

This instruction is privileged and context synchronizing.

Special Registers Altered:
MSR

Return From Debug Interrupt **C-form**

se_rfdi

MSR \leftarrow DSRR1
 NIA \leftarrow _{iea} DSRR0_{32:62} || 0b0

The **se_rfdi** instruction is used to return from a debug class interrupt, or as a means of establishing a new context and synchronizing on that new context simultaneously.

The contents of DSRR1 are placed into the MSR. If the new MSR value does not enable any pending exceptions, then the next instruction is fetched, under control of the new MSR value, from the address DSRR0_{0:62}||0b0. If the new MSR value enables one or more pending exceptions, the interrupt associated with the highest priority pending exception is generated; in this case the value placed into the save/restore registers by the interrupt processing mechanism (see Chapter 7 of Book III-E) is the address of the instruction that would have been executed next had the interrupt not occurred (that is, the address in DSRR0 at the time of the execution of **se_rfdi**).

This instruction is privileged and context synchronizing.

Special Registers Altered:

MSR

Corequisite Categories:

Embedded.Enhanced Debug

Return From Guest Interrupt **C-form**

se_rfgi

i

newmsr \leftarrow GSRR1
 if MSR_{GS} = 1 then
 newmsr_{GS,WE} \leftarrow MSR_{GS,WE}
 prots \leftarrow MSRP_{UCLEP,DEP,PMM}
 newmsr \leftarrow prots & MSR | ~prots & newmsr
 MSR \leftarrow newmsr
 NIA \leftarrow _{iea} GSRR0_{0:62} || 0b0

The **se_rfgi** instruction is used to return from a guest state base class interrupt, or as a means of simultaneously establishing a new context and synchronizing on that new context.

The contents of Guest Save/Restore Register 1 are placed into the MSR. If the **se_rfgi** is executed in the guest supervisor state (MSR_{GS PR} = 0b10), the bits MSR_{GS WE} are not modified and the bits MSR_{UCLEP DEP PMM} are modified only if the associated bits in the Machine State Register Protect (MSRP) Register are set to 0. If the new MSR value does not enable any pending exceptions, then the next instruction is fetched, under control of the new MSR value, from the address GSRR0_{0:62}||0b0. If the new MSR value enables one or more pending exceptions, the interrupt associated with the highest priority pending exception is generated; in this case the value placed into the associated save/restore register 0 by the interrupt processing mechanism is the address of the instruction that would have been executed next had the interrupt not occurred (i.e. the address in GSRR0 at the time of the execution of the **se_rfgi**).

This instruction is privileged and context synchronizing.

MSR

Corequisite Categories:

Embedded.Hypervisor

4.4 Condition Register Instructions

Condition Register instructions are provided to transfer values to and from various portions of the CR. Category VLE does not introduce any additional functionality beyond that defined in Book I for CR operations, but

does remap the CR-logical and *mcrf* instruction functionality into primary opcode 31. These instructions operate identically to the Book I instructions, but are encoded differently.

Condition Register AND *XL-form*

e_crand BT,BA,BB

31	BT	BA	BB	257	/
0	6	11	16	21	31

$$CR_{BT+32} \leftarrow CR_{BA+32} \& CR_{BB+32}$$

The bit in the Condition Register specified by BA+32 is ANDed with the bit in the Condition Register specified by BB+32, and the result is placed into the bit in the Condition Register specified by BT+32.

Chapter 5. Fixed-Point Instructions

5.1 Fixed-Point Load Instructions . . .	1147	5.7 Fixed-Point Trap Instructions	1163
5.2 Fixed-Point Store Instructions . . .	1151	5.8 Fixed-Point Select Instruction . . .	1163
5.3 Fixed-Point Load and Store with Byte Reversal Instructions	1154	5.9 Fixed-Point Logical, Bit, and Move Instructions	1164
5.4 Fixed-Point Load and Store Multiple Instructions	1154	5.10 Fixed-Point Rotate and Shift Instructions	1169
5.5 Fixed-Point Arithmetic Instructions	1155	5.11 Move To/From System Register Instructions	1172
5.6 Fixed-Point Compare and Bit Test Instructions	1159		

This section lists the fixed-point instructions supported by category VLE.

5.1 Fixed-Point Load Instructions

The fixed-point *Load* instructions compute the effective address (EA) of the memory to be accessed as described in Section 2.1, “Data Storage Addressing Modes”

The byte, halfword, word, or doubleword in storage addressed by EA is loaded into RT or RZ.

Category VLE supports both Big- and Little-Endian byte ordering for data accesses.

Some fixed-point load instructions have an update form in which RA is updated with the EA. For these forms, if $RA \neq 0$ and $RA \neq RT$, the EA is placed into RA and the memory element (byte, halfword, word, or doubleword) addressed by EA is loaded into RT. If $RA = 0$ or $RA = RT$,

the instruction form is invalid. This is the same behavior as specified for load with update instructions in Book I.

The fixed-point *Load* instructions from Book I, *lbzx*, *lbzux*, *lhzx*, *lhzux*, *lhax*, *lhaux*, *lwzx*, and *lwzux* are available while executing in VLE mode. The mnemonics, decoding, and semantics for these instructions are identical to those in Book I. See Section 3.3.2 of Book I for the instruction definitions.

The fixed-point *Load* instructions from Book I, *lwax*, *lwaux*, *ldx*, and *ldux* are available while executing in VLE mode on 64-bit implementations. The mnemonics, decoding, and semantics for these instructions are identical to those in Book I. See Section 3.3.2 of Book I for the instruction definitions.

Load Byte and Zero**D-form**

e_lbz RT,D(RA)

0	12	RT	RA	D	31
	6	11	16		

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + EXTS(D)
RT ← 560 || MEM(EA, 1)

```

Let the effective address (EA) be the sum (RAI0) + D. The byte in storage addressed by EA is loaded into RT_{56:63}. RT_{0:55} are set to 0.

Special Registers Altered:
None

Load Byte and Zero with Update D8-form

e_lbzu RT,D8(RA)

0	06	RT	RA	0	D8	31
	6	11	16	24		

```

EA ← (RA) + EXTS(D8)
RT ← 560 || MEM(EA, 1)
RA ← EA

```

Let the effective address (EA) be the sum (RA) + D8. The byte in storage addressed by EA is loaded into RT_{56:63}. RT_{0:55} are set to 0.

EA is placed into register RA.

If RA=0 or RA=RT, the instruction form is invalid.

Special Registers Altered:
None

Load Halfword and Zero**D-form**

e_lhz RT,D(RA)

0	22	RT	RA	D	31
	6	11	16		

```

if RA = 0 then b ← 0
else      b ← (RA)
EA ← b + EXTS(D)
RT ← 480 || MEM(EA, 2)

```

Let the effective address (EA) be the sum (RAI0) + D. The halfword in storage addressed by EA is loaded into RT_{48:63}. RT_{0:47} are set to 0.

5.2 Fixed-Point Store Instructions

The fixed-point *Store* instructions compute the EA of the memory to be accessed as described in Section 2.1, “Data Storage Addressing Modes”.

The contents of register RS or RZ are stored into the byte, halfword, word, or doubleword in storage addressed by EA.

Category VLE supports both Big- and Little-Endian byte ordering for data accesses.

Some fixed-point store instructions have an update form, in which register RA is updated with the effective address. For these forms, the following rules (from Book I) apply.

- If $RA \neq 0$, the effective address is placed into register RA.

- If $RS=RA$, the contents of register RS are copied to the target memory element and then EA is placed into register RA (RS).

The fixed-point *Store* instructions from Book I, ***stbx***, ***stbux***, ***sthx***, ***sthux***, ***stwx***, and ***stwux*** are available while executing in VLE mode. The mnemonics, decoding, and semantics for those instructions are identical to those in Book I; see Section 3.3.3 of Book I for the instruction definitions.

The fixed-point *Store* instructions from Book I, ***stdx*** and ***stdux*** are available while executing in VLE mode on 64-bit implementations. The mnemonics, decoding, and semantics for these instructions are identical to those in Book I; see Section 3.3.3 of Book I for the instruction definitions.

Special Registers Altered:

None

5.3 Fixed-Point Load and Store with Byte Reversal Instructions

The fixed-point *Load with Byte Reversal* and *Store with Byte Reversal* instructions from Book I, *lhbrx*, *lwbrx*, *sthbrx*, and *stwbrx* are available while executing in VLE mode. The mnemonics, decoding, and semantics for these instructions are identical to those in Book I. See Section 3.3.4 of Book I for the instruction definitions.

5.4 Fixed-Point Load and Store Multiple Instructions

The *Load/Store Multiple* instructions have preferred forms; see Section 1.8.1 of Book I. In the preferred forms storage alignment satisfies the following rule.

- The combination of the EA and RT (RS) is such that the low-order byte of GPR 31 is loaded (stored) from (into) the last byte of an aligned quadword in storage.

Load Multiple Word

D8-form

e_lmw RT,D8(RA)

```

if RA = 0 then b ← 0
else          b ← (RA)
EA ← b + EXTS(D8)
r ← RT
do while r ≤ 31
  GPR(r) ← 320 || MEM(EA,4)
  r ← r + 1
  EA ← EA + 4

```

Let $n = (32-RT)$. Let the effective address (EA) be the sum $(RA \ll 0) + D8$.

n consecutive words starting at EA are loaded into the low-order 32 bits of GPRs RT through 31. The high-order 32 bits of these GPRs are set to zero.

If RA is in the range of registers to be loaded, including the case in which $RA = 0$, the instruction form is invalid.

Special Registers Altered:

None

Store Multiple Word

D8-form

e_stmw RS,D8(RA)

```

if RA = 0 then b ← 0
else          b ← (RA)
EA ← b + EXTS(D8)
r ← RS
do while r ≤ 31
  MEM(EA,4) ← GPR(r)32:63
  r ← r + 1
  EA ← EA + 4

```

Let $n = (32-RS)$. Let the effective address (EA) be the sum $(RA \ll 0) + D8$.

n consecutive words starting at EA are stored from the low-order 32 bits of GPRs RS through 31.

Special Registers Altered:

None

5.5 Fixed-Point Arithmetic Instructions

The fixed-point *Arithmetic* instructions use the contents of the GPRs as source operands, and place results into GPRs, into status bits in the XER and into CR0.

The fixed-point *Arithmetic* instructions treat source operands as signed integers unless the instruction is explicitly identified as performing an unsigned operation.

The ***e_add2i*** instruction and other *Arithmetic* instructions with Rc=1 set the first three bits of CR0 to characterize the result placed into the target register. In 64-bit mode, these bits are set by signed comparison of the result to 0. In 32-bit mode, these bits are set by signed comparison of the low-order 32 bits of the result to zero.

e_addic and ***e_subfic*** always set CA to reflect the carry out of bit 0 in 64-bit mode and out of bit 32 in 32-bit mode.

The fixed-point *Arithmetic* instructions from Book I, ***add***[], ***addo***[], ***addc***[], ***addco***[], ***adde***[], ***addeo***[], ***addme***[], ***addmeo***[], ***addze***[], ***addzeo***[], ***divw***[], ***divwo***[], ***divwu***[], ***divwuo***[], ***mulhw***[], ***mulhwu***[], ***mullw***[], ***mullwo***[], ***neg***[], ***nego***[], ***subf***[], ***subfo***[], ***subfe***[], ***subfeo***[], ***subfme***[], ***subfmeo***[], ***subfze***[], ***subfzeo***[], ***subfc***[], and ***subfco***[] are available while executing in VLE mode. The mnemonics, decoding, and semantics for these instructions are identical to those in Book I; see Section 3.3.8 of Book I for the instruction definitions.

The fixed-point *Arithmetic* instructions from Book I, ***mulld***[], ***mulldo***[], ***mulhd***[], ***mulhdu***[], ***muldu***[], ***divd***[], ***divdo***[], ***divdu***[], and ***divduo***[] are available while executing in VLE mode on 64-bit implementations. The mnemonics, decoding, and semantics for those instructions are identical to these in Book I; see Section 3.3.8 of Book I for the instruction definitions.

If the processor is in 64-bit mode and register RX contains the most negative 64-bit number (0x8000_0000_0000_0000), the result is the most negative 64-bit number. Similarly, if the processor is in 32-bit mode and register RX contains the most negative 32-bit number (0x8000_0000), the result is the most negative 32-bit number.

Special Registers Altered:

None

5.6 Fixed-Point Compare and Bit Test Instructions

The fixed-point *Compare* instructions compare the contents of register RA or register RX with one of the following:

- The value of the scaled immediate field *sci8* formed from the F, UI8, and SCL fields as:

$$sci8 \leftarrow {}^{56-SCL \times 8}_F \parallel UI8 \parallel {}^{SCL \times 8}_F$$
- The zero-extended value of the UI field
- The zero-extended value of the UI5 field
- The sign-extended value of the SI field
- The contents of register RB or register RY.

The following comparisons are signed: ***e_cmph***, ***e_cmpi***, ***e_cmp16i***, ***e_cmph16i***, ***se_cmp***, ***se_cmph***, and ***se_cmpi***.

The following comparisons are unsigned: ***e_cmphl***, ***e_cmpli***, ***e_cmphl16i***, ***e_cmpl16i***, ***se_cmpli***, ***se_cmpl***, and ***se_cmphl***.

The fixed-point *Bit Test* instruction tests the bit specified by the UI5 instruction field and sets the CR0 field as follows.

Bit Name Description

0	LT	Always set to 0
1	GT	$RX_{ui5} = 1$
2	EQ	$RX_{ui5} = 0$
3	SO	Summary overflow from the XER

The fixed-point *Compare* instructions from Book I, ***cmp*** and ***cmpl*** are available while executing in VLE mode. The mnemonics, decoding, and semantics for these instructions are identical to those in Book I; see Section 3.3.9 of Book I for the instruction definitions.

Bit Test Immediate

5.7 Fixed-Point Trap Instructions

The fixed-point *Trap* instruction from Book I, *tw* is available while executing in VLE mode. The mnemonics, decoding, and semantics for this instruction is identical to that in Book I; see Section 3.3.10 of Book I for the instruction definition.

The fixed-point *Trap* instruction from Book I, *td* is available while executing in VLE mode on 64-bit implementations. The mnemonic, decoding, and semantics for the *td* instruction are identical to those in Book I; see Section 3.3.10 of Book I for the instruction definitions.

5.8 Fixed-Point Select Instruction

The fixed-point *Select* instruction provides a means to select one of two registers and place the result in a destination register under the control of a predicate value supplied by a CR bit.

The fixed-point *Select* instruction from Book I, *isel* is available while executing in VLE mode. The mnemonics, decoding, and semantics for this instruction is identical to that in Book I; see Section of Book I for the instruction definition.

5.9 Fixed-Point Logical, Bit, and Move Instructions

The *Logical* instructions perform bit-parallel operations on 64-bit operands. The *Bit* instructions manipulate a bit, or create a bit mask, in a register. The *Move* instructions move a register or an immediate value into a register.

The X-form Logical instructions with Rc=1, the SCI8-form Logical instructions with Rc=1, the RR-form Logical instructions with Rc=1, the *e_and2i*. instruction, and the *e_and2is*. instruction set the first three bits of CR field 0 as the arithmetic instructions described in Section 5.5, “Fixed-Point Arithmetic Instructions”. (Also see Section 4.1.1.) The Logical instructions do not change the SO, OV, and CA bits in the XER.

The fixed-point *Logical* instructions from Book I, *and[.]*, *or[.]*, *xor[.]*, *nand[.]*, *nor[.]*, *eqv[.]*, *andc[.]*, *orc[.]*, *extsb[.]*, *extsh[.]*, *cntlzw[.]*, and *popcntb* are available while executing in VLE mode. The mnemonics, decoding, and semantics for these instructions are identical to those in Book I; see Section 3.3.12 of Book I for the instruction definitions.

The fixed-point *Logical* instructions from Book I, *extsw[.]* and *cntlzd[.]* are available while executing in VLE mode on 64-bit implementations. The mnemonics, decoding, and semantics for these instructions are identical to those in Book I; see Section 3.3.12 of Book I for the instruction definitions.

Chapter 6. Storage Control Instructions

6.1 Storage Synchronization Instructions	1173	6.4 TLB Management Instructions . .	1174
6.2 Cache Management Instructions	1174	6.5 Instruction Alignment and Byte Ordering.	1174
6.3 Cache Locking Instructions. . . .	1174		

6.1 Storage Synchronization Instructions

The memory synchronization instructions implemented by category VLE are identical in semantics to those defined in Book II and Book III-E. The ***se_isync*** instruction is defined by category VLE, but has the same semantics as ***isync***.

The *Load and Reserve* and *Store Conditional* instructions from Book II, ***lbarx***, ***lharx***, ***lwarx***, ***stbcx.***, ***sthcx.***, and ***stwcx.***, are available while executing in VLE mode. The mnemonics, decoding, and semantics for those instructions are identical to those in Book II; see Section 4.4.2 of Book II for the instruction definitions.

The *Load and Reserve* and *Store Conditional* instructions from Book II, ***ldarx*** and ***stdcx.*** are available while executing in VLE mode on 64-bit implementations. The mnemonics, decoding, and semantics for those instructions are identical to those in Book II; see Section 4.4.2 of Book II for the instruction definitions.

The *Memory Barrier* instructions from Book II, ***sync*** and ***mbar*** are available while executing in VLE mode. The mnemonics, decoding, and semantics for those instructions are identical to those in Book II; see Section 4.4.3 of Book II for the instruction definitions.

The ***wait*** instruction from Book II is available while executing in VLE mode if the category Wait is implemented. The mnemonics, decoding, and semantics for ***wait*** are identical to those in Book II; see Section 4.4 of Book II for the instruction definition.

C-form

se_isync

Executing an ***se_isync*** instruction ensures that all instructions preceding the ***se_isync*** instruction have completed before the ***se_isync*** instruction completes, and that no subsequent instructions are initiated until after the ***se_isync*** instruction completes. It also ensures that all instruction cache block invalidations caused by ***icbi*** instructions preceding the ***se_isync*** instruction have been performed with respect to the processor executing the ***se_isync*** instruction, and then causes any prefetched instructions to be discarded.

Except as described in the preceding sentence, the ***se_isync*** instruction may complete before storage accesses associated with instructions preceding the ***se_isync*** instruction have been performed. This instruction is context synchronizing.

The ***se_isync*** instruction has identical semantics to the Book II ***isync*** instruction, but has a different encoding.

Special Registers Altered:

None

6.2 Cache Management Instructions

Cache management instructions implemented by category VLE are identical to those defined in Book II and Book III-E.

The *Cache Management* instructions from Book II, **dcb**, **dcbf**, **dcbst**, **dcbt**, **dcbtst**, **dcbz**, **icbi**, and **icbt** are available while executing in VLE mode. The mnemonics, decoding, and semantics for these instructions are identical to those in Book II; see Section 4.3 of Book II for the instruction definitions.

The *Cache Management* instruction from Book III-E, **dcbi** is available while executing in VLE mode. The mnemonics, decoding, and semantics for this instruction are identical to those in Book III-E; see Section 6.11.1 of Book III-E for the instruction definition.

6.3 Cache Locking Instructions

Cache locking instructions implemented by category VLE are identical to those defined in Book III-E. If the *Cache Locking* instructions are implemented in category VLE, the category Embedded Cache Locking must also be implemented.

The *Cache Locking* instructions from Book III-E, **dcbtls**, **dcbtstls**, **dcblic**, **icbtls**, and **icblic** are available while executing in VLE mode. The mnemonics, decoding, and semantics for these instructions are identical to those in Book III-E; see Section 6.11.2 of Book III-E for the instruction definitions.

6.4 TLB Management Instructions

The *TLB Management* instructions implemented by category VLE are identical to those defined in Book III-E.

The *TLB Management* instructions from Book III-E, **tlbre**, **tlbwe**, **tlbivax**, **tlbilx** <E.HV>, **tlbsync**, **tlbsrx** <E.TWC>, and **tlbsx** are available while executing in VLE mode. The mnemonics, decoding, and semantics for these instructions are identical to those in Book III-E. See Section 6.11.4.9 of Book III-E.

Instructions and resources described in Chapter 6 of Book III-E are available if the appropriate category is implemented.

6.5 Instruction Alignment and Byte Ordering

Only Big-Endian instruction memory is supported when executing from a page of VLE instructions. Attempting to fetch VLE instructions from a page marked as Little-Endian generates an instruction storage interrupt byte-ordering exception.

Chapter 7. Additional Categories Available in VLE

7.1 Move Assist	1175	7.8 Embedded Performance	
7.2 Vector	1175	Monitor.	1176
7.3 Signal Processing Engine.	1175	7.9 Processor Control	1176
7.4 Embedded Floating Point	1175	7.10 Decorated Storage	1176
7.5 Embedded Hypervisor	1175	7.11 Embedded Cache	
7.6 Legacy Move Assist	1175	Initialization	1176
7.7 External PID	1176	7.12 Embedded Cache Debug	1176

Instructions and resources from categories other than Base and Embedded are available in VLE. These include categories for which all the instructions in the category use primary opcode 4 or primary opcode 31.

7.1 Move Assist

Move Assist instructions implemented by category VLE are identical to those defined in Book I. If category Move Assist is supported in non-VLE mode, *Move Assist* instructions are also supported in VLE mode. The mnemonics, decoding, and semantics for those instructions are identical to those in Book I; see Section 3.3.6 of Book I for the instruction definitions.

7.2 Vector

Vector instructions implemented by category VLE are identical to those defined in Book I. If category Vector is supported in non-VLE mode, *Vector* instructions are also supported in VLE mode. The mnemonics, decoding, and semantics for those instructions are identical to those in Book I; see Chapter 6 of Book I for the instruction definitions.

7.3 Signal Processing Engine

Signal Processing Engine instructions implemented by category VLE are identical to those defined in Book I. If category Signal Processing Engine is supported in non-VLE mode, *Signal Processing Engine* instructions are also supported in VLE mode. The mnemonics, decoding, and semantics for those instructions are identical to those in Book I; see Chapter 8 of Book I for the instruction definitions.

7.4 Embedded Floating Point

Embedded Floating Point instructions implemented by category VLE are identical to those defined in Book I. If category SPE.Embedded Float Scalar Double, SPE.Embedded Float Scalar Single, or SPE.Embedded Float Vector is supported in non-VLE mode, the appropriate *Embedded Floating Point* instructions are also supported in VLE mode. The mnemonics, decoding, and semantics for those instructions are identical to those in Book I; see Chapter 9 of Book I for the instruction definitions.

7.5 Embedded Hypervisor

Embedded Hypervisor instructions implemented by category VLE are not identical to those defined in Book III - E. The *ehpriv* instruction is identical in mnemonics, decoding, and semantics to the instruction defined in Book III-E. See Section 4.3.1 of Book III-E for the instruction definition. The *sc* instruction which provides a LEV field for executing calls to the hypervisor software is implemented as *e_sc*, which is defined in Section 4.3 of Book VLE. The *rtgi* instruction is implemented as *se_rtgi*, which is also defined in Section 4.3 of Book VLE. If category *Embedded Hypervisor* is supported in non-VLE mode, Embedded Hypervisor instructions are also supported in VLE mode.

7.6 Legacy Move Assist

Legacy Move Assist instructions implemented by category VLE are identical to those defined in Book I. If category Legacy Move Assist is supported in non-VLE mode, *Legacy Move Assist* instructions are also sup-

ported in VLE mode. The mnemonics, decoding, and semantics for those instructions are identical to those in Book I; see Chapter 10 of Book I for the instruction definitions.

7.7 External PID

External Process ID instructions implemented by category VLE are identical to those defined in Book III-E. If category Embedded.External PID is supported in non-VLE mode, *External Process ID* instructions are also supported in VLE mode. The mnemonics, decoding, and semantics for those instructions are identical to those in Book III-E; see Chapter 5.3.6 of Book III-E for the instruction definitions.

7.8 Embedded Performance Monitor

Embedded Performance Monitor instructions implemented by category VLE are identical to those defined in Book III-E. If category Embedded.Performance Monitor is supported in non-VLE mode, *Embedded Performance Monitor* instructions are also supported in VLE mode. The mnemonics, decoding, and semantics for those instructions are identical to those in Book III-E; see Appendix D of Book III-E for the instruction definitions.

7.9 Processor Control

Processor Control instructions implemented by category VLE are identical to those defined in Book III-E. If category Embedded.Processor Control is supported in non-VLE mode, *Processor Control* instructions are also supported in VLE mode. The mnemonics, decoding, and semantics for those instructions are identical to those in Book III-E; see Chapter 11 of Book III-E for the instruction definitions.

7.10 Decorated Storage

Decorated Storage instructions implemented by category VLE are identical to those defined in Book II. If category *Decorated Storage* is supported in non-VLE mode, *Decorated Storage* instructions are also supported in VLE mode. The mnemonics, decoding, and semantics for those instructions are identical to those in Book II; see Chapter 6 of Book II for the instruction definitions.

7.11 Embedded Cache Initialization

Embedded Cache Initialization instructions implemented by category VLE are identical to those defined in Book III-E. If category Embedded.Cache Initialization is supported in non-VLE mode, *Embedded Cache Initialization* instructions are also supported in VLE mode. The mnemonics, decoding, and semantics for those instructions are identical to those in Book III-E; Chapter A.1 of Book III-E for the instruction definitions.

7.12 Embedded Cache Debug

Embedded Cache Debug instructions implemented by category VLE are identical to those defined in Book III-E. If category Embedded.Cache Debug is supported in non-VLE mode, *Embedded Cache Debug* instructions are also supported in VLE mode. The mnemonics, decoding, and semantics for those instructions are identical to those in Book III-E; Chapter A.2 of Book III-E for the instruction definitions.

Appendix A. VLE Instruction Set Sorted by Mnemonic

This appendix lists all the instructions available in VLE mode in the Power ISA, in order by mnemonic. Opcodes that are not defined below are treated as illegal by category VLE.

Form	Opcode (hexadecimal) ²	Mode Dep. ¹	Priv.	Cat ¹	Mnemonic	Instruction
XO	7C000214	SR		B	add[o][.]	Add

¹ See the key to the mode dependency and privilege columns on page 1324 and the key to the category column in Section 1.3.5 of Book I.

² For 16-bit instructions, the “Opcode” column represents the 16-bit hexadecimal instruction encoding with the opcode and extended opcode in the corresponding fields in the instruction, and with 0’s in bit positions which are not opcode bits; dashes are used following the opcode to indicate the form is a 16-bit instruction. For 32-bit instructions, the “Opcode” column represents the 32-bit hexadecimal instruction encoding with the opcode, extended opcode, and other fields with fixed values in the corresponding fields in the instruction, and with 0...s in bit positions which are not opcode, extended opcode or fixed value bits.

Appendix B. VLE Instruction Set Sorted by Opcode

This appendix lists all the instructions available in VLE mode in the Power ISA , in order by opcode. Opcodes that are not defined below are treated as illegal by category VLE.

Form	Opcode (hexadecimal) ²	Mode Dep. ¹	Priv.	Cat ¹	Mnemonic	Instruction
C	0000----			VLE	se_illegal	Illegal
C	0001----			VLE	se_isync	Instruction Synchronize
C	0002----			VLE	se_sc	System Call
C	0004----			VLE	se_blr[l]	Branch to Link Register [and Link]
C	0006----			VLE	se_bctr[l]	Branch to Count Register [and Link]
C	0008----		P	VLE	se_rfi	Return From Interrupt
C	0009----		H	VLE	se_rfc	Return From Critical Interrupt

¹ See the key to the mode dependency and privilege column below and the key to the category column in Section 1.3.5 of Book I.

²For 16-bit instructions, the "Opcode" column represents the 16-bit hexadecimal instruction encoding with the opcode and extended opcode in the corresponding fields in the instruction, and with 0's in bit positions which are not opcode bits; dashes are used following the opcode to indicate the form is a 16-bit instruction. For 32-bit instructions, the "Opcode" column represents the 32-bit hexadecimal instruction encoding with the opcode, extended opcode, and other fields with fixed values in the corresponding fields in the instruction, and with 0's in bit positions which are not opcode, extended opcode or fixed value bits."

Mode Dependency and Privilege Abbreviations

Except as described below and in Section 1.10.3, "Effective Address Calculation", in Book I, all instructions are independent of whether the processor is in 32-bit or 64-bit mode.

Mode Dep. Description

- | | |
|----|--|
| CT | If the instruction tests the Count Register, it tests the low-order 32 bits in 32-bit mode and all 64 bits in 64-bit mode. |
| SR | The setting of status registers (such as XER and CR0) is mode-dependent. |

Mode Dep. Description

- | | |
|----|---|
| 32 | The instruction must be executed only in 32-bit mode. |
| 64 | The instruction must be executed only in 64-bit mode. |

Key to Privilege Column

Priv. Description

- | | |
|---|---|
| P | Denotes a privileged instruction. |
| O | Denotes an instruction that is treated as privileged or nonprivileged (or hypervisor, for <i>mtspr</i>), depending on the SPR or PMR number. |
| M | Denotes an instruction that is treated as privileged or nonprivileged, depending on the value of the UCLE bit of the MSR. |
| H | Denotes an instruction that can be executed only in hypervisor state. |

Power ISA Book I-III Appendices

Appendix A. Incompatibilities with the POWER Architecture

This appendix identifies the known incompatibilities that must be managed in the migration from the POWER Architecture to the Power ISA. Some of the incompatibilities can, at least in principle, be detected by the processor, which could trap and let software simulate the POWER operation. Others cannot be detected by the processor even in principle.

In general, the incompatibilities identified here are those that affect a POWER application program. Incompatibilities for instructions that can be used only by POWER operating system programs are not necessarily discussed. Discussion of incompatibilities that pertain only to operating system programs assumes the Server environment (because there is no need for POWER operating system programs to run in the Embedded environment).

A.1 New Instructions, Formerly Privileged Instructions

Instructions new to Power ISA typically use opcode values (including extended opcode) that are illegal in POWER. A few instructions that are privileged in POWER (e.g., *dclz*, called *dcbz* in Power ISA) have been made nonprivileged in Power ISA. Any POWER program that executes one of these now-valid or now-nonprivileged instructions, expecting to cause the system illegal instruction error handler or the system privileged instruction error handler to be invoked, will not execute correctly on Power ISA.

A.2 Newly Privileged Instructions

The following instructions are nonprivileged in POWER but privileged in Power ISA.

mfmsr
mfsr

A.3 Reserved Fields in Instructions

These fields are shown with “/”s in the instruction layouts. In both POWER and Power ISA these fields are ignored by the processor. The Power ISA states that these fields must contain zero. The POWER Architecture lacks such a statement, but it is expected that essentially all POWER programs contain zero in these fields.

In several cases the Power ISA assumes that reserved fields in POWER instructions indeed contain zero. The cases include the following.

- *bclr[l]* and *bcctr[l]* assume that bits 19:20 in the POWER instructions contain zero.
- *cmpi*, *cmp*, *cmpli*, and *cmpl* assume that bit 10 in the POWER instructions contains zero.
- *mtspr* and *mfspr* assume that bits 16:20 in the POWER instructions contain zero.
- *mtcrf* and *mfcrr* assume that bit 11 in the POWER instructions is contains zero.
- *Synchronize* assumes that bits 9:10 in the POWER instruction (*dcs*) contain zero. (This assumption provides compatibility for application programs, but not necessarily for operating system programs; see Section A.22.)
- *mtmsr* assumes that bit 15 in the POWER instruction contains zero.

A.4 Reserved Bits in Registers

Both POWER and Power ISA permit software to write any value to these bits. However in POWER reading such a bit always returns 0, while in Power ISA reading it may return either 0 or the value that was last written to it.

A.5 Alignment Check

The POWER MSR AL bit (bit 24) is no longer supported; the corresponding Power ISA MSR bit, bit 56, is reserved. The low-order bits of the EA are always used. (Notice that the value 0 — the normal value for a reserved bit — means “ignore the low-order EA bits” in

POWER, and the value 1 means “use the low-order EA bits”.) POWER-compatible operating system code will probably write the value 1 to this bit.

A.6 Condition Register

The following instructions specify a field in the CR explicitly (via the BF field) and also, in POWER, use bit 31 as the Record bit. In Power ISA, bit 31 is a reserved field for these instructions and is ignored by the processor. In POWER, if bit 31 contains 1 the instructions execute normally (i.e., as if the bit contained 0) except as follows:

cmp	CR0 is undefined if Rc=1 and BF≠0
cmpl	CR0 is undefined if Rc=1 and BF≠0
mcrxr	CR0 is undefined if Rc=1 and BF≠0
fcmpu	CR1 is undefined if Rc=1
fcmpo	CR1 is undefined if Rc=1
mcrfs	CR1 is undefined if Rc=1 and BF≠1

A.7 LK and Rc Bits

For the instructions listed below, if bit 31 (LK or Rc bit in POWER) contains 1, in POWER the instruction executes as if the bit contained 0 except as follows: if LK=1, the Link Register is set (to an undefined value, except for **svc**); if Rc=1, Condition Register Field 0 or 1 is set to an undefined value. In Power ISA, bit 31 is a reserved field for these instructions and is ignored by the processor.

Power ISA instructions for which bit 31 is the LK bit in POWER:

sc (**svc** in POWER)
the *Condition Register Logical* instructions
mcrf
isync (**ics** in POWER)

Power ISA instructions for which bit 31 is the Rc bit in POWER:

fixed-point X-form *Load* and *Store* instructions
fixed-point X-form *Compare* instructions
the X-form *Trap* instruction
mtspr, **mfspr**, **mcrf**, **mcrxr**, **mfcrr**, **mtocrf**, **mfcrrf**
floating-point X-form *Load* and *Store* instructions
floating-point *Compare* instructions
mcrfs
dcbz (**dclz** in POWER)

A.8 BO Field

POWER shows certain bits in the BO field — used by *Branch Conditional* instructions — as “x”. Although the POWER Architecture does not say how these bits are

to be interpreted, they are in fact ignored by the processor.

Power ISA shows these bits as “z”, “a”, or “t”. The “z” bits are ignored, as in POWER. However, the “a” and “t” bits can be used by software to provide a hint about how the branch is likely to behave. If a POWER program has the “wrong” value for these bits, the program will produce the same results as on POWER but performance may be affected.

A.9 BH Field

Bits 19:20 of the *Branch Conditional to Link Register* and *Branch Conditional to Count Register* instructions are reserved in POWER but are defined as a branch hint (BH) field in Power ISA. Because these bits are hints, they may affect performance but do not affect the results of executing the instruction.

A.10 Branch Conditional to Count Register

For the case in which the Count Register is decremented and tested (i.e., the case in which BO₂=0), POWER specifies only that the branch target address is undefined, with the implication that the Count Register, and the Link Register if LK=1, are updated in the normal way. Power ISA specifies that this instruction form is invalid.

A.11 System Call

There are several respects in which Power ISA is incompatible with POWER for *System Call* instructions — which in POWER are called *Supervisor Call* instructions.

- POWER provides a version of the *Supervisor Call* instruction (bit 30 = 0) that allows instruction fetching to continue at any one of 128 locations. It is used for “fast SVCs”. Power ISA provides no such version: if bit 30 of the instruction is 0 the instruction form is invalid.
- POWER provides a version of the *Supervisor Call* instruction (bits 30:31 = 0b11) that resumes instruction fetching at one location and sets the Link Register to the address of the next instruction. Power ISA provides no such version: bit 31 is a reserved field.
- For POWER, information from the MSR is saved in the Count Register. For Power ISA this information is saved in SRR1.
- In POWER bits 16:19 and 27:29 of the instruction comprise defined instruction fields or a portion

thereof, while in Power ISA these bits comprise reserved fields.

- In POWER bits 20:26 of the instruction comprise a portion of the SV field, while in Power ISA these bits comprise the LEV field.
- POWER saves the low-order 16 bits of the instruction, in the Count Register. Power ISA does not save them.
- The settings of MSR bits by the associated interrupt differ between POWER and Power ISA; see *POWER Processor Architecture* and Book III.

A.12 Fixed-Point Exception Register (XER)

Bits 48:55 of the XER are reserved in Power ISA, while in POWER the corresponding bits (16:23) are defined and contain the comparison byte for the *lscbx* instruction (which Power ISA lacks).

A.13 Update Forms of Storage Access Instructions

Power ISA requires that RA not be equal to either RT (fixed-point *Load* only) or 0. If the restriction is violated the instruction form is invalid. POWER permits these cases, and simply avoids saving the EA.

A.14 Multiple Register Loads

Power ISA requires that RA, and RB if present in the instruction format, not be in the range of registers to be loaded, while POWER permits this and does not alter RA or RB in this case. (The Power ISA restriction applies even if RA=0, although there is no obvious benefit to the restriction in this case since RA is not used to compute the effective address if RA=0.) If the Power ISA restriction is violated, either the system illegal instruction error handler is invoked or the results are boundedly undefined. The instructions affected are:

lmw (*lm* in POWER)
lswi (*lsi* in POWER)
lswx (*lsx* in POWER)

For example, an *lmw* instruction that loads all 32 registers is valid in POWER but is an invalid form in Power ISA.

A.15 Load/Store Multiple Instructions

There are two respects in which Power ISA is incompatible with POWER for *Load Multiple* and *Store Multiple* instructions.

- If the EA is not word-aligned, in Power ISA either an Alignment exception occurs or the addressed bytes are loaded, while in POWER an Alignment interrupt occurs if $MSR_{AL}=1$ (the low-order two bits of the EA are ignored if $MSR_{AL}=0$).
- In Power ISA the instruction may be interrupted by a system-caused interrupt, while in POWER the instruction cannot be thus interrupted.

A.16 Move Assist Instructions

There are several respects in which Power ISA is incompatible with POWER for *Move Assist* instructions.

- In Power ISA an *lswx* instruction with zero length leaves the contents of RT undefined (if $RT \neq RA$ and $RT \neq RB$) or is an invalid instruction form (if $RT=RA$ or $RT=RB$), while in POWER the corresponding instruction (*lsx*) is a no-op in these cases.
- In Power ISA a *Move Assist* instruction may be interrupted by a system-caused interrupt, while in POWER the instruction cannot be thus interrupted.

A.17 Move To/From SPR

There are several respects in which Power ISA is incompatible with POWER for *Move To/From Special Purpose Register* instructions.

- The SPR field is ten bits long in Power ISA, but only five in POWER (see also Section A.3, “Reserved Fields in Instructions”).
- *mfspr* can be used to read the Decrementer in problem state in POWER, but only in privileged state in Power ISA.
- If the SPR value specified in the instruction is not one of the defined values, POWER behaves as follows.
 - If the instruction is executed in problem state and $SPR_0=1$, a Privileged Instruction type Program interrupt occurs. No architected registers are altered except those set by the interrupt.
 - Otherwise no architected registers are altered.

In this same case, Power ISA behaves as follows.

- If the instruction is executed in problem state, a Hypervisor Emulation Assistance interrupt occurs if $spr_0=0$ and a Privileged Instruction

type Program interrupt occurs if $spr_0=1$. No architected registers are altered except those set by the interrupt.

- If the instruction is executed in privileged state, a Hypervisor Emulation Assistance interrupt occurs if the SPR value is 0 or, for *mfspr* only, if the SPR value is 4, 5, or 6. In these cases no architected registers are altered except those set by the interrupt. Otherwise no operation is performed. (See Section 4.4.4, “Move To/From System Register Instructions” in Book III-S.)

A.18 Effects of Exceptions on FPSCR Bits FR and FI

For the following cases, POWER does not specify how FR and FI are set, while Power ISA preserves them for Invalid Operation Exception caused by a *Compare* instruction, sets FI to 1 and FR to an undefined value for disabled Overflow Exception, and clears them otherwise.

- Invalid Operation Exception (enabled or disabled)
- Zero Divide Exception (enabled or disabled)
- Disabled Overflow Exception

A.19 Store Floating-Point Single Instructions

There are several respects in which Power ISA is incompatible with POWER for *Store Floating-Point Single* instructions.

- POWER uses $FPSCR_{UE}$ to help determine whether denormalization should be done, while Power ISA does not. Using $FPSCR_{UE}$ is in fact incorrect: if $FPSCR_{UE}=1$ and a denormalized single-precision number is copied from one storage location to another by means of *lfs* followed by *stfs*, the two “copies” may not be the same.
- For an operand having an exponent that is less than 874 (unbiased exponent less than -149), POWER stores a zero (if $FPSCR_{UE}=0$) while Power ISA stores an undefined value.

A.20 Move From FPSCR

POWER defines the high-order 32 bits of the result of *mfs* to be $0xFFFF_FFFF$, while Power ISA copies the high-order 32-bits of the FPSCR.

A.21 Zeroing Bytes in the Data Cache

The *dclz* instruction of POWER and the *dcbz* instruction of Power ISA have the same opcode. However, the functions differ in the following respects.

- *dclz* clears a line while *dcbz* clears a block.
- *dclz* saves the EA in RA (if $RA \neq 0$) while *dcbz* does not.
- *dclz* is privileged while *dcbz* is not.

A.22 Synchronization

The *Synchronize* instruction (called *dcs* in POWER) and the *isync* instruction (called *ics* in POWER) cause more pervasive synchronization in Power ISA than in POWER. However, unlike *dcs*, *Synchronize* does not wait until data cache block writes caused by preceding instructions have been performed in main storage. Also, *Synchronize* has an L field while *dcs* does not, and some uses of the instruction by the operating system require $L=2<S>$. (The L field corresponds to reserved bits in *dcs* and hence is expected to be zero in POWER programs; see Section A.3.)

A.23 Move To Machine State Register Instruction

The *mtmsr* instruction has an L field in Power ISA but not in POWER. The function of the variant of *mtmsr* with $L=1$ differs from the function of the instruction in the POWER architecture in the following ways.

- In Power ISA, this variant of *mtmsr* modifies only the EE and RI bits of the MSR, while in the POWER *mtmsr* modifies all bits of the MSR.
- This variant of *mtmsr* is execution synchronizing in Power ISA but is context synchronizing in POWER. (The POWER architecture lacks Power ISA’s distinction between execution synchronization and context synchronization. The statement in the POWER architecture specification that *mtmsr* is “synchronizing” is equivalent to stating that the instruction is context synchronizing.)

Also, *mtmsr* is optional in Power ISA but required in POWER.

A.24 Direct-Store Segments

POWER’s direct-store segments are not supported in Power ISA.

A.25 Segment Register Manipulation Instructions

The definitions of the four *Segment Register Manipulation* instructions *mtsr*, *mtsrin*, *mfsr*, and *mfsrin* differ in two respects between POWER and Power ISA. Instructions similar to *mtsrin* and *mfsrin* are called *mtsri* and *mfsri* in POWER.

privilege: *mfsr* and *mfsri* are problem state instructions in POWER, while *mfsr* and *mfsrin* are privileged in Power ISA.

function: the “indirect” instructions (*mtsri* and *mfsri*) in POWER use an RA register in computing the Segment Register number, and the computed EA is stored into RA (if $RA \neq 0$ and $RA \neq RT$), while in Power ISA *mtsrin* and *mfsrin* have no RA field and the EA is not stored.

mtsr, *mtsrin* (*mtsri*), and *mfsr* have the same opcodes in Power ISA as in POWER. *mfsri* (POWER) and *mfsrin* (Power ISA) have different opcodes.

Also, the *Segment Register Manipulation* instructions are required in POWER whereas they are optional in Power ISA.

A.26 TLB Entry Invalidation

The *tlbi* instruction of POWER and the *tlbie* instruction of Power ISA have the same opcode. However, the functions differ in the following respects.

- *tlbi* computes the EA as $(RAI0) + (RB)$, while *tlbie* lacks an RA field and computes the EA and related information as (RB) .
- *tlbi* saves the EA in RA (if $RA \neq 0$), while *tlbie* lacks an RA field and does not save the EA.
- For *tlbi* the high-order 36 bits of RB are used in computing the EA, while for *tlbie* these bits contain additional information that is not directly related to the EA.
- For *tlbi* has no RS operand, while for *tlbie* the (RS) is an LPID value used to qualify the TLB invalidation.

Also, *tlbi* is required in POWER whereas *tlbie* is optional in Power ISA.

A.27 Alignment Interrupts

Placing information about the interrupting instruction into the DSISR and the DAR when an Alignment interrupt occurs is optional in Power ISA but required in POWER.

A.28 Floating-Point Interrupts

POWER uses MSR bit 20 to control the generation of interrupts for floating-point enabled exceptions, and Power ISA uses the corresponding MSR bit, bit 52, for the same purpose. However, in Power ISA this bit is part of a two-bit value that controls the occurrence, precision, and recoverability of the interrupt, while in POWER this bit is used independently to control the occurrence of the interrupt (in POWER all floating-point interrupts are precise).

A.29 Timing Facilities

A.29.1 Real-Time Clock

The POWER Real-Time Clock is not supported in Power ISA. Instead, Power ISA provides a Time Base. Both the RTC and the TB are 64-bit Special Purpose Registers, but they differ in the following respects.

- The RTC counts seconds and nanoseconds, while the TB counts “ticks”. The ticking rate of the TB is implementation-dependent.
- The RTC increments discontinuously: 1 is added to RTCU when the value in RTCL passes 999_999_999. The TB increments continuously: 1 is added to TBU when the value in TBL passes 0xFFFF_FFFF.
- The RTC is written and read by the *mtspr* and *mfspr* instructions, using SPR numbers that denote the RTCU and RTCL. The TB is written and read by the same instructions using different SPR numbers.
- The SPR numbers that denote POWER’s RTCL and RTCU are invalid in Power ISA.
- The RTC is guaranteed to increment at least once in the time required to execute ten *Add Immediate* instructions. No analogous guarantee is made for the TB.
- Not all bits of RTCL need be implemented, while all bits of the TB must be implemented.

A.29.2 Decrementer

The Power ISA Decrementer differs from the POWER Decrementer in the following respects.

- The Power ISA DEC decrements at the same rate that the TB increments, while the POWER DEC decrements every nanosecond (which is the same rate that the RTC increments).
- Not all bits of the POWER DEC need be implemented, while all bits of the Power ISA DEC must be implemented.
- The interrupt caused by the DEC has its own interrupt vector location in Power ISA, but is considered an External interrupt in POWER.

A.30 Deleted Instructions

The following instructions are part of the POWER Architecture but have been dropped from the Power ISA.

<i>abs</i>	Absolute
<i>clcs</i>	Cache Line Compute Size
<i>clf</i>	Cache Line Flush
<i>cli</i> (*)	Cache Line Invalidate
<i>dclst</i>	Data Cache Line Store
<i>div</i>	Divide
<i>divs</i>	Divide Short
<i>doz</i>	Difference Or Zero
<i>dozi</i>	Difference Or Zero Immediate
<i>lscbx</i>	Load String And Compare Byte Indexed
<i>maskg</i>	Mask Generate
<i>maskir</i>	Mask Insert From Register
<i>mfsri</i>	Move From Segment Register Indirect
<i>mul</i>	Multiply
<i>nabs</i>	Negative Absolute
<i>rac</i> (*)	Real Address Compute
<i>rfi</i> (*)	Return From Interrupt
<i>rfsvc</i>	Return From SVC
<i>rlmi</i>	Rotate Left Then Mask Insert
<i>rrib</i>	Rotate Right And Insert Bit
<i>sle</i>	Shift Left Extended
<i>sleq</i>	Shift Left Extended With MQ
<i>sliq</i>	Shift Left Immediate With MQ
<i>slliq</i>	Shift Left Long Immediate With MQ
<i>slq</i>	Shift Left Long With MQ
<i>slq</i>	Shift Left With MQ
<i>sraiq</i>	Shift Right Algebraic Immediate With MQ
<i>sraq</i>	Shift Right Algebraic With MQ
<i>sre</i>	Shift Right Extended
<i>srea</i>	Shift Right Extended Algebraic
<i>sreq</i>	Shift Right Extended With MQ
<i>sriq</i>	Shift Right Immediate With MQ
<i>srlmq</i>	Shift Right Long Immediate With MQ
<i>srlq</i>	Shift Right Long With MQ
<i>srq</i>	Shift Right With MQ

(*) This instruction is privileged.

Note: Many of these instructions use the MQ register. The MQ is not defined in the Power ISA.

MNEM	PRI	XOP
<i>abs</i>	31	360
<i>clcs</i>	31	531
<i>clf</i>	31	118

<i>srlmq</i>	31	760
<i>srlq</i>	31	728
<i>srq</i>	31	664

(*) This instruction is privileged.

Assembler Note

It might be helpful to current software writers for the Assembler to flag the discontinued POWER instructions.

A.31 Discontinued Opcodes

The opcodes listed below are defined in the POWER Architecture but have been dropped from the Power ISA. The list contains the POWER mnemonic (MNEM), the primary opcode (PRI), and the extended opcode (XOP) if appropriate. The corresponding instructions are reserved in Power ISA.

A.32 POWER2 Compatibility

The POWER2 instruction set is a superset of the POWER instruction set. Some of the instructions added for POWER2 are included in the Power ISA. Those that have been renamed in the Power ISA are listed in this

section, as are the new POWER2 instructions that are not included in the Power ISA.

Other incompatibilities are also listed.

A.32.1 Cross-Reference for Changed POWER2 Mnemonics

The following table lists the new POWER2 instruction mnemonics that have been changed in the Power ISA User Instruction Set Architecture, sorted by POWER2 mnemonic.

To determine the Power ISA mnemonic for one of these POWER2 mnemonics, find the POWER2 mnemonic in

the second column of the table: the remainder of the line gives the Power ISA mnemonic and the page on which the instruction is described, as well as the instruction names.

POWER2 mnemonics that have not changed are not listed.

Page	POWER2		Power ISA	
	Mnemonic	Instruction	Mnemonic	Instruction
142	fcir[.]	Floating Convert Double to Integer with Round	fctiw[.]	Floating Convert To Integer Word
143	fcirz[.]	Floating Convert Double to Integer with Round to Zero	fctiwz[.]	Floating Convert To Integer Word with round toward Zero

A.32.2 Load/Store Floating-Point Double

Several of the opcodes for the *Load/Store Floating-Point Quad* instructions of the POWER2 architecture have been reclaimed by the *Load/Store Floating-Point Double [Indexed]* instructions (entries with a ‘-’ in the Power ISA column have not been reclaimed):

MNEMONIC			
POWER2	POWER ISA	PRI	XOP
<i>lfq</i>	<i>lq</i>	56	-
<i>lfqu</i>	<i>lfdp</i>	57	0
<i>lfqux</i>	-	31	823
<i>lfqx</i>	<i>lfdpx</i>	31	791
<i>stfq</i>	-	60	-
<i>stfqu</i>	<i>stfdp</i>	61	-
<i>stfqux</i>	-	31	951
<i>stfqx</i>	<i>stfdpx</i>	31	919

Differences between the *l/stfdp[x]* instructions and the POWER2 *l/stfq[u][x]* instructions include the following.

- The storage operand for the *l/stfdp[x]* instructions must be quadword aligned for optimal performance.
- The register pairs for the *l/stfdp[x]* instructions must be even-odd pairs, instead of any consecutive pair.
- The *l/stfdp[x]* instructions do not have update forms.

A.32.3 Floating-Point Conversion to Integer

The *fcir* and *fcirz* instructions of POWER2 have the same opcodes as do the *fctiw* and *fctiwz* instructions, respectively, of Power ISA. However, the functions differ in the following respects.

- *fcir* and *fcirz* set the high-order 32 bits of the target FPR to 0xFFFF_FFFF, while *fctiw* and *fctiwz* set them to an undefined value.
- Except for enabled Invalid Operation Exceptions, *fcir* and *fcirz* set the FPRF field of the FPSCR based on the result, while *fctiw* and *fctiwz* set it to an undefined value.
- *fcir* and *fcirz* do not affect the VXSNAN bit of the FPSCR, while *fctiw* and *fctiwz* do.
- *fcir* and *fcirz* set FPSCR_{XX} to 1 for certain cases of “Large Operands” (i.e., operands that are too large to be represented as a 32-bit signed fixed-point integer), while *fctiw* and *fctiwz* do not alter it for any case of “Large Operand”. (The IEEE standard requires not altering it for “Large Operands”.)

A.32.4 Floating-Point Interrupts

POWER2 uses MSR bits 20 and 23 to control the generation of interrupts for floating-point enabled exceptions, and Power ISA uses the corresponding MSR bits, bits 52 and 55, for the same purpose. However, in Power ISA these bits comprise a two-bit value that controls the occurrence, precision, and recoverability of the interrupt, while in POWER2 these bits are used independently to control the occurrence (bit 20) and the precision (bit 23) of the interrupt. Moreover, in Power ISA all floating-point interrupts are considered Program interrupts, while in POWER2 imprecise floating-point interrupts have their own interrupt vector location.

A.32.5 Trace

The Trace interrupt vector location differs between the two architectures, and there are many other differences.

A.33 Deleted Instructions

The following instructions are new in POWER2 implementations of the POWER Architecture but have been dropped from the Power ISA.

<i>lfq</i>	Load Floating-Point Quad
<i>lfqu</i>	Load Floating-Point Quad with Update
<i>lfqux</i>	Load Floating-Point Quad with Update Indexed
<i>lfqx</i>	Load Floating-Point Quad Indexed
<i>stfq</i>	Store Floating-Point Quad
<i>stfqu</i>	Store Floating-Point Quad with Update
<i>stfqux</i>	Store Floating-Point Quad with Update Indexed
<i>stfqx</i>	Store Floating-Point Quad Indexed

A.33.1 Discontinued Opcodes

The opcodes listed below are new in POWER2 implementations of the POWER Architecture but have been dropped from the Power ISA. The list contains the POWER2 mnemonic (MNEM), the primary opcode (PRI), and the extended opcode (XOP) if appropriate. The instructions are either illegal or reserved in Power ISA; see Appendix D.

MNEM	PRI	XOP
<i>lfq</i>	56	-
<i>lfqx</i>	31	791
<i>stfqx</i>	31	919

Appendix B. Platform Support Requirements

As described in Chapter 1 of Book I, the architecture is structured as a collection of categories. Each category is comprised of facilities and/or instructions that together provide a unit of functionality. The Server and Embedded categories are referred to as “special” because all implementations must support at least one of these categories. Each special category, when taken together with the Base category, is referred to as an “environment”, and provides the minimum functionality required to develop operating systems and applications.

Every processor implementation supports at least one of the environments, and may also support a set of categories chosen based on the target market for the implementation. However, a Server implementation supports only those categories designated as part of the Server platform in Figure 21. To facilitate the development of operating systems and applications for a well-defined purpose or customer set, usually embodied in a unique hardware platform, this appendix documents the association between a platform and the set of categories it requires.

Adding a new platform may permit cost-performance optimization by clearly identifying a unique set of categories. However, this has the potential to fragment the application base. As a result, new platforms will be added only when the optimization benefit clearly outweighs the loss due to fragmentation.

The platform support requirements are documented in Figure 21. An “x” in a column indicates that the category is required. A “+” in a column indicates that the requirement is being phased in.

- This register is not defined for this instruction.
¹ Note that the order of the two 5-bit halves of the SPR number is reversed.

Figure 22. SPR Numbers (Sheet 3 of 4)

decimal	SPR ¹		Register Name	Privileged		Length (bits)	Cat ²
	spr _{5:9}	spr _{0:4}		mtspr	mfspir		
2	See Section 1.3.5 of Book I. If multiple categories are listed separated by a semicolon, all the listed categories must be implemented in order for the other columns of the line to apply. A comma separates two alternatives, and takes precedence over a semicolon; e.g., the EPCR (E.HV,E;64) must be implemented if either (a) category E.HV is implemented or (b) the processor is an Embedded processor that implements the 64-Bit category.						
3	This register is a hypervisor resource, and can be accessed by this instruction only in hypervisor state (see Chapter 2 of Book III-S or Chapter 2 of Book III-E as appropriate).						
4	<S>This register is a hypervisor resource, and can be accessed by this instruction only in hypervisor state (see Chapter 2 of Book III-S). <E>If the Embedded.Hypervisor category is supported, this register is a hypervisor resource, and can be accessed by this instruction only in hypervisor state (see Chapter 2 of Book III-E). Otherwise the register is privileged.						
5	This register cannot be directly written. Instead, bits in the register corresponding to 1 bits in (RS) can be cleared using <i>mtspr SPR,RS</i> .						
6	The register can be written by the <i>dcread</i> instruction.						
7	The register can be written by the <i>icread</i> instruction.						
8	This register cannot be directly written. Instead, bits in the register corresponding to 0 bits in (RS) can be cleared using <i>mtspr SPR,RS</i> .						
9	The value specified in register RS may be masked by the contents of the [U]AMOR before being placed into the AMR; see the <i>mtspr</i> instruction description in Book III-S.						
10	The value specified in register RS may be ANDed with the contents of the AMOR before being placed into the UAMOR; see the <i>mtspr</i> instruction description in Book III-S.						
11	The register is Category: Phased-in.						
12	If the Embedded.Hypervisor category is supported, this register is a hypervisor resource, and can be accessed by this instruction only in hypervisor state (see Chapter 2 of Book III-E). Otherwise the register is privileged for Embedded.						
13	If the Embedded.Hypervisor category is supported, this register is a hypervisor resource and can be accessed by this instruction only in hypervisor state, and guest references to the register are redirected to the corresponding guest register (see Chapter 2 of Book III-E). Otherwise the register is privileged.						
All SPR numbers that are not shown above and are not implementation-specific are reserved.							

Figure 22. SPR Numbers (Sheet 4 of 4)

Appendix D. Illegal Instructions

With the exception of the instruction consisting entirely of binary 0s, the instructions in this class are available for future extensions of the Power ISA; that is, some future version of the Power ISA may define any of these instructions to perform new functions.

The following primary opcodes are illegal.

1, 5, 6

The following primary opcodes have unused extended opcodes. Their unused extended opcodes can be determined from the opcode maps in Appendix F of Book Appendices. All unused extended opcodes are illegal.

4, 19, 30, 31, 56, 5, 58, 59, 60, 62, 63

An instruction consisting entirely of binary 0s is illegal, and is guaranteed to be illegal in all future versions of this architecture.

Appendix E. Reserved Instructions

The instructions in this class are allocated to specific purposes that are outside the scope of the Power ISA.

The following types of instruction are included in this class.

1. The instruction having primary opcode 0, except the instruction consisting entirely of binary 0s (which is an illegal instruction; see Section 1.7.2, “Illegal Instruction Class” on page 22) and the extended opcode shown below.

256 Service Processor “Attention”

2. Instructions for the POWER Architecture that have not been included in the Power ISA. These are listed in Section A.31, “Discontinued Opcodes” and Section A.33.1, “Discontinued Opcodes”.
3. Implementation-specific instructions used to conform to the Power ISA specification.
4. Any other implementation-dependent instructions that are not defined in the Power ISA.

Appendix F. Opcode Maps

This appendix contains tables showing the opcodes and extended opcodes.

For the primary opcode table (Table 3 on page 1235), each cell is in the following format.

Opcode in Decimal	Opcode in Hexadecimal
Instruction Mnemonic	
Category	Instruction Format

The category abbreviations are shown on Section 1.3.5 of Book I. However, the categories “Phased-In”, “Phased-Out”, and floating-point “Record” are not listed in the opcode tables.

The extended opcode tables show the extended opcode in decimal, the instruction mnemonic, the category, and the instruction format. These tables appear in order of primary opcode within three groups. The first group consists of the primary opcodes that have small extended opcode fields (2-4 bits), namely 30, 58, and 62. The second group consists of primary opcodes that have 11-bit extended opcode fields. The third group consists of primary opcodes that have 10-bit extended opcode fields. The tables for the second and third groups are rotated.

In the extended opcode tables several special markings are used.

- A prime (′) following an instruction mnemonic denotes an additional cell, after the lowest-numbered one, used by the instruction. For example, **subfc** occupies cells 8 and 520 of primary opcode 31, with the former corresponding to OE=0 and the latter to OE=1. Similarly, **sradi** occupies cells 826 and 827, with the former corresponding to sh₅=0 and the latter to sh₅=1 (the 9-bit extended opcode 413, shown on page 96, excludes the sh₅ bit).
- Two vertical bars (||) are used instead of primed mnemonics when an instruction occupies an entire column of a table. The instruction mnemonic is repeated in the last cell of the column.
- For primary opcode 31, an asterisk (*) in a cell that would otherwise be empty means that the cell is

reserved because it is “overlaid”, by a fixed-point or *Storage Access* instruction having only a primary opcode, by an instruction having an extended opcode in primary opcode 30, 58, or 62, or by a potential instruction in any of the categories just mentioned. The overlaying instruction, if any, is also shown. A cell thus reserved should not be assigned to an instruction having primary opcode 31. (The overlaying is a consequence of opcode decoding for fixed-point instructions: the primary opcode, and the extended opcode if any, are mapped internally to a 10-bit “compressed opcode” for ease of subsequent decoding on some implementations that complied with previous versions of the architecture.)

- Parentheses around the opcode or extended opcode mean that the instruction was defined in earlier versions of the Power ISA but is no longer defined in the Power ISA.
- Curly brackets around the opcode or extended opcode mean that the instruction will be defined in future versions of the Power ISA.
- **long** is used as filler for mnemonics that are longer than a table cell.

An empty cell, a cell containing only an asterisk, or a cell in which the opcode or extended opcode is parenthesized, corresponds to an illegal instruction.

The instruction consisting entirely of binary 0s causes the system illegal instruction error handler to be invoked for all members of the POWER family, and this is likely to remain true in future models (it is guaranteed in the Power ISA). An instruction having primary opcode 0 but not consisting entirely of binary 0s is reserved except for the following extended opcode (instruction bits 21:30).

256 Service Processor “Attention” (Power ISA only)

Appendix G. Power ISA Instruction Set Sorted by Category

This appendix lists all the instructions in the Power ISA, grouped by category, and in order by mnemonic within category.

Form	Opcode		Mode	Dep. ¹	Priv. ¹	Page	Cat ¹	Mnemonic	Instruction
	Pri	Ext							
X	31	252				86	64	bpermd	Bit Permute Doubleword
X	31	58	SR			85	64	cntlzd[.]	Count Leading Zeros Doubleword
XO	31	489	SR			72	64	divd[o][.]	Divide Doubleword
XO	31	425	SR			73	64	divde[o][.]	Divide Doubleword Extended
XO	31	393	SR			73	64	divdeu[o][.]	Divide Doubleword Extended Unsigned
XO	31	457	SR			72	64	divdu[o][.]	Divide Doubleword Unsigned
X	31	986	SR			85	64	extsw[.]	Extend Sign Word
DS	58	0				50	64	ld	Load Doubleword
X	31	84				699	64	ldarx	Load Doubleword And Reserve Indexed
X	31	532				56	64	ldbrx	Load Doubleword Byte-Reverse Indexed
DS	58	1				50	64	ldu	Load Doubleword with Update
X	31	53				50	64	ldux	Load Doubleword with Update Indexed
X	31	21				50	64	ldx	Load Doubleword Indexed
DS	58	2				49	64	lwa	Load Word Algebraic
X	31	373				49	64	lwaux	Load Word Algebraic with Update Indexed
X	31	341				49	64	lwx	Load Word Algebraic Indexed
XO	31	73	SR			71	64	mulhd[.]	Multiply High Doubleword
XO	31	9	SR			71	64	mulhdu[.]	Multiply High Doubleword Unsigned
XO	31	233	SR			71	64	mulld[o][.]	Multiply Low Doubleword
X	31	186				84	64	prtyd	Parity Doubleword
MDS	30	8	SR			91	64	rldcl[.]	Rotate Left Doubleword then Clear Left
MDS	30	9	SR			92	64	rldcr[.]	Rotate Left Doubleword then Clear Right
MD	30	2	SR			91	64	rldic[.]	Rotate Left Doubleword Immediate then Clear
MD	30	0	SR			90	64	rldicl[.]	Rotate Left Doubleword Immediate then Clear Left
MD	30	1	SR			90	64	rldicr[.]	Rotate Left Doubleword Immediate then Clear Right
MD	30	3	SR			92	64	rldimi[.]	Rotate Left Doubleword Immediate then Mask Insert
X	31	27	SR			95	64	sld[.]	Shift Left Doubleword
X	31	794	SR			96	64	srad[.]	Shift Right Algebraic Doubleword
XS	31	413	SR			96	64	sradi[.]	Shift Right Algebraic Doubleword Immediate
X	31	539	SR			95	64	srd[.]	Shift Right Doubleword
DS	62	0				54	64	std	Store Doubleword
X	31	660				56	64	stdbrx	Store Doubleword Byte-Reverse Indexed
X	31	214				699	64	stdcx.	Store Doubleword Conditional Indexed
DS	62	1				54	64	stdu	Store Doubleword with Update
X	31	181				54	64	stdux	Store Doubleword with Update Indexed
X	31	149				54	64	stdx	Store Doubleword Indexed
X	31	68				77	64	td	Trap Doubleword
D	2					77	64	tdi	Trap Doubleword Immediate
XO	31	266	SR			63	B	add[o][.]	Add
XO	31	10	SR			64	B	addc[o][.]	Add Carrying
XO	31	138	SR			65	B	adde[o][.]	Add Extended
D	14					62	B	addi	Add Immediate
D	12		SR			63	B	addic	Add Immediate Carrying
D	13		SR			63	B	addic.	Add Immediate Carrying and Record
D	15					62	B	addis	Add Immediate Shifted

Form	Opcode		Mode	Dep. ¹	Priv ¹	Page	Cat ¹	Mnemonic	Instruction
	Pri	Ext							
XO	31	234	SR			65	B	addme[o][.]	Add to Minus One Extended
XO	31	202	SR			66	B	addze[o][.]	Add to Zero Extended
X	31	28	SR			80	B	and[.]	AND
X	31	60	SR			81	B	andc[.]	AND with Complement
D	28		SR			78	B	andi.	AND Immediate
D	29		SR			78	B	andis.	AND Immediate Shifted
I	18					35	B	b[l][a]	Branch
B	16		CT			35	B	bc[l][a]	Branch Conditional
XL	19	528	CT			36	B	bcctr[l]	Branch Conditional to Count Register
XL	19	16	CT			36	B	bclr[l]	Branch Conditional to Link Register
X	31	0				74	B	cmp	Compare
X	31	508				82	B	cmpb	Compare Bytes
D	11					74	B	cmpi	Compare Immediate
X	31	32				75	B	cmpl	Compare Logical
D	10					75	B	cmpli	Compare Logical Immediate
X	31	26	SR			81	B	cntlzw[.]	Count Leading Zeros Word
XL	19	257				37	B	crand	Condition Register AND
XL	19	129				38	B	crandc	Condition Register AND with Complement
XL	19	289				38	B	creqv	Condition Register Equivalent
XL	19	225				37	B	crnand	Condition Register NAND
XL	19	33				38	B	crnor	Condition Register NOR
XL	19	449				37	B	cror	Condition Register OR
XL	19	417				38	B	crorc	Condition Register OR with Complement
XL	19	193				37	B	crxor	Condition Register XOR
X	31	86				691	B	dcbf	Data Cache Block Flush
X	31	54				691	B	dcbst	Data Cache Block Store
X	31	278				688	B	dcbt	Data Cache Block Touch
X	31	246				689	B	dcbtst	Data Cache Block Touch for Store
X	31	1014				691	B	dcbz	Data Cache Block set to Zero
XO	31	491	SR			68	B	divw[o][.]	Divide Word
XO	31	427	SR			69	B	divwe[o][.]	Divide Word Extended
XO	31	395	SR			69	B	divweu[o][.]	Divide Word Extended Unsigned
XO	31	459	SR			68	B	divwu[o][.]	Divide Word Unsigned
X	31	284	SR			81	B	eqv[.]	Equivalent
X	31	954	SR			81	B	extsb[.]	Extend Sign Byte
X	31	922	SR			81	B	extsh[.]	Extend Sign Halfword
X	31	982				680	B	icbi	Instruction Cache Block Invalidate
A	31	15				77	B	isel	Integer Select
XL	19	150				693	B	isync	Instruction Synchronize
X	31	52				694	B	lbarx	Load Byte and Reserve Indexed
D	34					45	B	lbz	Load Byte and Zero
D	35					45	B	lbzu	Load Byte and Zero with Update
X	31	119				45	B	lbzux	Load Byte and Zero with Update Indexed
X	31	87				46	B	lbzx	Load Byte and Zero Indexed
D	42					47	B	lha	Load Halfword Algebraic
X	31	116				695	B	lharx	Load Halfword and Reserve Indexed
D	43					47	B	lhau	Load Halfword Algebraic with Update
X	31	375				47	B	lhaux	Load Halfword Algebraic with Update Indexed
X	31	343				47	B	lhax	Load Halfword Algebraic Indexed
X	31	790				55	B	lhbrx	Load Halfword Byte-Reverse Indexed
D	40					46	B	lhz	Load Halfword and Zero
D	41					46	B	lhzu	Load Halfword and Zero with Update
X	31	311				46	B	lhzux	Load Halfword and Zero with Update Indexed
X	31	279				46	B	lhzx	Load Halfword and Zero Indexed
D	46					57	B	lmw	Load Multiple Word
X	31	20				694	B	lwarx	Load Word And Reserve Indexed
X	31	534				55	B	lwbrx	Load Word Byte-Reverse Indexed
D	32					48	B	lwz	Load Word and Zero
D	33					48	B	lwzu	Load Word and Zero with Update
X	31	55				48	B	lwzux	Load Word and Zero with Update Indexed
X	31	23				48	B	lwzx	Load Word and Zero Indexed

Form	Opcode		Mode	Dep.1	Priv	Page	Cat ¹	Mnemonic	Instruction
	Pri	Ext							
XL	19	0				38	B	mcrf	Move Condition Register Field

D	25					79	B	oris	OR Immediate Shifted
X	31	122				83	B	popcntb	Population Count Bytes
X	31	506				85	B	popcntd	Population Count Doubleword
X	31	378				83	B	popcntw	Population Count Word
X	31	154				84	B	prtyw	Parity Word
M	20		SR			89	B	rlwimi[.]	Rotate Left Word Immediate then Mask Insert
M	21		SR			87	B	rlwinm[.]	Rotate Left Word Immediate then AND with Mask
M	23		SR			88	B	rlwnm[.]	Rotate Left Word then AND with Mask
SC	17					39, 745, 908	B	sc	System Call
X	31	24	SR			93	B	slw[.]	Shift Left Word
X	31	792	SR			94	B	sraw[.]	Shift Right Algebraic Word
X	31	824	SR			94	B	srawi[.]	Shift Right Algebraic Word Immediate
X	31	536	SR			93	B	srw[.]	Shift Right Word
D	38					51	B	stb	Store Byte
X	31	694				696	B	stbcx.	Store Byte Conditional Indexed
D	39					51	B	stbu	Store Byte with Update
X	31	247				51	B	stbux	Store Byte with Update Indexed
X	31	215				51	B	stbx	Store Byte Indexed
D	44					52	B	sth	Store Halfword
X	31	918				55	B	sthbrx	Store Halfword Byte-Reverse Indexed
X	31	726				697	B	sthcx.	Store Halfword Conditional Indexed
D	45					52	B	sthu	Store Halfword with Update
X	31	439				52	B	sthux	Store Halfword with Update Indexed
X	31	407				52	B	sthx	Store Halfword Indexed
D	47					57	B	stmw	Store Multiple Word
D	36					53	B	stw	Store Word
X	31	662				55	B	stwbrx	Store Word Byte-Reverse Indexed
X	31	150				698	B	stwcx.	Store Word Conditional Indexed
D	37					53	B	stwu	Store Word with Update
X	31	183				53	B	stwux	Store Word with Update Indexed
X	31	151				53	B	stwx	Store Word Indexed
XO	31	40	SR			63	B	subf[o][.]	Subtract From
XO	31	8	SR			64	B	subfc[o][.]	Subtract From Carrying
XO	31	136	SR			65	B	subfe[o][.]	Subtract From Extended
D	8		SR			64	B	subfc	Subtract From Immediate Carrying
XO	31	232	SR			65	B	subfme[o][.]	Subtract From Minus One Extended
XO	31	200	SR			66	B	subfze[o][.]	Subtract From Zero Extended
X	31	598				701	B	sync	Synchronize

Form	Opcode		Mode	Dep.1	Priv	Page	Cat ¹	Mnemonic	Instruction
	Pri	Ext							
X	31	566			H	817, 1010 ,905	B	tlsync	TLB Synchronize
X	31	4				76	B	tw	Trap Word
D	3					76	B	twi	Trap Word Immediate
X	31	316	SR			80	B	xor[.]	XOR
D	26					79	B	xori	XOR Immediate
D	27					79	B	xoris	XOR Immediate Shifted
XO	31	74			H	97	BCDA	addg6s	Add and Generate Sixes
X	31	314			H	97	BCDA	cbcdtd	Convert Binary Coded Decimal to Declets
X	31	282			H	97	BCDA	cdtbcd	Convert Declets To Binary Coded Decimal
X	59	2				173	DFP	dadd[.]	DFP Add
X	63	2				173	DFP	daddq[.]	DFP Add Quad
X	59	802				195	DFP	dcffix[.]	DFP Convert From Fixed
X	63	802				195	DFP	dcffixq[.]	DFP Convert From Fixed Quad

Appendix H. Power ISA Instruction Set Sorted by Opcode

This appendix lists all the instructions in the Power ISA, in order by opcode.

Form	Opcode		Mode	Dep. ¹	Priv ¹	Page	Cat ¹	Mnemonic	Instruction
	Pri	Ext							
D	2				77	64		tdi	Trap Doubleword Immediate
D	3				76	B		twi	Trap Word Immediate
VX	4	0			231	V		vaddubm	Vector Add Unsigned Byte Modulo
VX	4	2			248	V		vmaxub	Vector Maximum Unsigned Byte
VX	4	4			255	V		vrlb	Vector Rotate Left Byte
VC	4	6			251	V		vcmpequb[.]	Vector Compare Equal To Unsigned Byte
X	4	8			599	LMA		mulhhwu[.]	Multiply High Halfword to Word Unsigned
VX	4	8			237	V		vmuloub	Vector Multiply Odd Unsigned Byte
VX	4	10			259	V		vaddfp	Vector Add Single-Precision
XO	4	12			596	LMA		machhwu[o][.]	Multiply Accumulate High Halfword to Word Modulo Unsigned
VX	4	12			224	V		vmrghb	Vector Merge High Byte
VX	4	14			221	V		vpkuhum	Vector Pack Unsigned Halfword Unsigned Modulo
VA	4	32			238	V		vmhaddshs	Vector Multiply-High-Add Signed Halfword Saturate
VA	4	33			238	V		vmhraddshs	Vector Multiply-High-Round-Add Signed Halfword Saturate
VA	4	34			239	V		vmladduhm	Vector Multiply-Low-Add Unsigned Halfword Modulo
VA	4	36			239	V		vmsumubm	Vector Multiply-Sum Unsigned Byte Modulo
VA	4	37			240	V		vmsummbm	Vector Multiply-Sum Mixed Byte Modulo
VA	4	38			241	V		vmsumuhm	Vector Multiply-Sum Unsigned Halfword Modulo
VA	4	39			242	V		vmsumuhs	Vector Multiply-Sum Unsigned Halfword Saturate
X	4	40			599	LMA		mulhhw[.]	Multiply High Halfword to Word Signed
VA	4	40			240	V		vmsumshm	Vector Multiply-Sum Signed Halfword Modulo
VA	4	41			241	V		vmsumshs	Vector Multiply-Sum Signed Halfword Saturate
VA	4	42			227	V		vsel	Vector Select
VA	4	43			227	V		vperm	Vector Permute
XO	4	44			595	LMA		machhw[o][.]	Multiply Accumulate High Halfword to Word Modulo Signed
VA	4	44			228	V		vsldoi	Vector Shift Left Double by Octet Immediate
XO	4	46			601	LMA		nmachhw[o][.]	Negative Multiply Accumulate High Halfword to Word Modulo Signed
VA	4	46			260	V		vmaddfp	Vector Multiply-Add Single-Precision
VA	4	47			260	V		vnmsubfp	Vector Negative Multiply-Subtract Single-Precision
VX	4	64			231	V		vadduhm	Vector Add Unsigned Halfword Modulo
VX	4	66			248	V		vmaxuh	Vector Maximum Unsigned Halfword
VX	4	68			255	V		vrlh	Vector Rotate Left Halfword
VC	4	70			251	V		vcmpequh[.]	Vector Compare Equal To Unsigned Halfword
VX	4	72			237	V		vmulouh	Vector Multiply Odd Signed Halfword
VX	4	74			259	V		vsubfp	Vector Subtract Single-Precision
XO	4	76			596	LMA		machhwsu[o][.]	Multiply Accumulate High Halfword to Word Saturate Unsigned
VX	4	76			224	V		vmrghh	Vector Merge High Halfword
VX	4	78			221	V		vpkuwum	Vector Pack Unsigned Word Unsigned Modulo
EVS	4	79			549	SP		evsel	Vector Select
XO	4	108			595	LMA		machhws[o][.]	Multiply Accumulate High Halfword to Word Saturate Signed

Form	Opcode		Mode	Dep. ¹	Priv ¹	Page	Cat ¹	Mnemonic	Instruction
	Pri	Ext							
XO	4	110				601	LMA	nmachw[s][o][.]	Negative Multiply Accumulate High Halfword to Word Saturate Signed
VX	4	128				231	V	vadduwm	Vector Add Unsigned Word Modulo
VX	4	130				248	V	vmaxuw	Vector Maximum Unsigned Word
VX	4	132				255	V	vrlw	Vector Rotate Left Word
VC	4	134				252	V	vcmpequw[.]	Vector Compare Equal To Unsigned Word
X	4	136				598	LMA	mulchw[.]	Multiply Cross Halfword to Word Unsigned
XO	4	140				594	LMA	macchw[s][o][.]	Multiply Accumulate Cross Halfword to Word Modulo Unsigned
VX	4	140				224	V	vmrghw	Vector Merge High Word
VX	4	142				221	V	vpkhus	Vector Pack Unsigned Halfword Unsigned Saturate
X	4	168				598	LMA	mulchw[.]	Multiply Cross Halfword to Word Signed
XO	4	172				593	LMA	macchw[s][o][.]	Multiply Accumulate Cross Halfword to Word Modulo Signed
XO	4	174				600	LMA	nmacchw[s][o][.]	Negative Multiply Accumulate Cross Halfword to Word Modulo Signed
VC	4	198				265	V	vcmpeqfp[.]	Vector Compare Equal To Single-Precision
XO	4	204				594	LMA	macchwsu[s][o][.]	Multiply Accumulate Cross Halfword to Word Saturate Unsigned
VX	4	206				221	V	vpkuws	Vector Pack Unsigned Word Unsigned Saturate
XO	4	236				593	LMA	macchws[s][o][.]	Multiply Accumulate Cross Halfword to Word Saturate Signed
XO	4	238				600	LMA	nmacchws[s][o][.]	Negative Multiply Accumulate Cross Halfword to Word Saturate Signed
VX	4	258				247	V	vmaxsb	Vector Maximum Signed Byte
VX	4	260				256	V	vslb	Vector Shift Left Byte
VX	4	264				237	V	vmulosb	Vector Multiply Odd Signed Byte
VX	4	266				268	V	vrefp	Vector Reciprocal Estimate Single-Precision
VX	4	268				225	V	vmrglb	Vector Merge Low Byte
VX	4	270				220	V	vpkshus	Vector Pack Signed Halfword Unsigned Saturate
VX	4	322				247	V	vmaxsh	Vector Maximum Signed Halfword
VX	4	324				256	V	vslh	Vector Shift Left Halfword
VX	4	328				237	V	vmulosh	Vector Multiply Odd Signed Halfword
VX	4	330				268	V	vrsqrtefp	Vector Reciprocal Square Root Estimate Single-Precision
VX	4	332				225	V	vmrglh	Vector Merge Low Halfword
VX	4	334				220	V	vpkswus	Vector Pack Signed Word Unsigned Saturate
VX	4	384				230	V	vaddcuw	Vector Add and Write Carry-Out Unsigned Word
VX	4	386				247	V	vmaxsw	Vector Maximum Signed Word
VX	4	388				256	V	vslw	Vector Shift Left Word
X	4	392				599	LMA	mullhw[.]	Multiply Low Halfword to Word Unsigned
VX	4	394				267	V	vexptefp	Vector 2 Raised to the Exponent Estimate Floating-Point
XO	4	396				598	LMA	maclhw[s][o][.]	Multiply Accumulate Low Halfword to Word Modulo Unsigned
VX	4	396				225	V	vmrglw	Vector Merge Low Word
VX	4	398				220	V	vpkshss	Vector Pack Signed Halfword Signed Saturate
X	4	424				599	LMA	mullhw[.]	Multiply Low Halfword to Word Signed
XO	4	428				597	LMA	maclhw[s][o][.]	Multiply Accumulate Low Halfword to Word Modulo Signed
XO	4	430				602	LMA	nmaclhw[s][o][.]	Negative Multiply Accumulate Low Halfword to Word Modulo Signed
VX	4	452				228	V	vsl	Vector Shift Left
VC	4	454				266	V	vcmpgefp[.]	Vector Compare Greater Than or Equal To Single-Precision
VX	4	458				267	V	vlogefp	Vector Log Base 2 Estimate Floating-Point
XO	4	460				598	LMA	maclhwsu[s][o][.]	Multiply Accumulate Low Halfword to Word Saturate Unsigned
VX	4	462				220	V	vpkswss	Vector Pack Signed Word Signed Saturate

Appendix I. Power ISA Instruction Set Sorted by Mnemonic

This appendix lists all the instructions in the Power ISA, in order by mnemonic.

Form	Opcode		Mode	Dep. ¹	Priv ¹	Page	Cat ¹	Mnemonic	Instruction
	Pri	Ext							
XO	31	266	SR			63	B	add[o].]	Add
XO	31	10	SR			64	B	addc[o].]	Add Carrying
XO	31	138	SR			65	B	adde[o].]	Add Extended
XO	31	74			H	97	BCDA	addg6s	Add and Generate Sixes
D	14					62	B	addi	Add Immediate
D	12		SR			63	B	addic	Add Immediate Carrying
D	13		SR			63	B	addic.	Add Immediate Carrying and Record
D	15					62	B	addis	Add Immediate Shifted
XO	31	234	SR			65	B	addme[o].]	Add to Minus One Extended
XO	31	202	SR			66	B	addze[o].]	Add to Zero Extended
X	31	28	SR			80	B	and[.]	AND
X	31	60	SR			81	B	andc[.]	AND with Complement
D	28		SR			78	B	andi.	AND Immediate
D	29		SR			78	B	andis.	AND Immediate Shifted
I	18					35	B	b[l][a]	Branch
B	16		CT			35	B	bc[l][a]	Branch Conditional
XL	19	528	CT			36	B	bcctr[l]	Branch Conditional to Count Register
XL	19	16	CT			36	B	bclr[l]	Branch Conditional to Link Register
X	31	252				86	64	bpermd	Bit Permute Doubleword
EVX	4	527				510	SP	brinc	Bit Reversed Increment
X	31	314			H	97	BCDA	cbcdtd	Convert Binary Coded Decimal to Declets
X	31	282			H	97	BCDA	cdtbcd	Convert Declets To Binary Coded Decimal
X	31	0				74	B	cmp	Compare
X	31	508				82	B	cmpb	Compare Bytes
D	11					74	B	cmpi	Compare Immediate
X	31	32				75	B	cmpl	Compare Logical
D	10					75	B	cmpli	Compare Logical Immediate
X	31	58	SR			85	64	cntlzd[.]	Count Leading Zeros Doubleword
X	31	26	SR			81	B	cntlzw[.]	Count Leading Zeros Word
XL	19	257				37	B	crand	Condition Register AND
XL	19	129				38	B	crandc	Condition Register AND with Complement
XL	19	289				38	B	creqv	Condition Register Equivalent
XL	19	225				37	B	crnand	Condition Register NAND
XL	19	33				38	B	crnor	Condition Register NOR
XL	19	449				37	B	cror	Condition Register OR
XL	19	417				38	B	crorc	Condition Register OR with Complement
XL	19	193				37	B	crxor	Condition Register XOR
X	59	2				173	DFP	dadd[.]	DFP Add
X	63	2				173	DFP	daddq[.]	DFP Add Quad
X	31	758				687	E	dcba	Data Cache Block Allocate
X	31	86				691	B	dcbf	Data Cache Block Flush
X	31	127			P	932	E.PD	dcbfep	Data Cache Block Flush by External PID
X	31	470			P	988	E	dcbi	Data Cache Block Invalidate
X	31	390			M	992	ECL	dcblc	Data Cache Block Lock Clear
X	31	54				691	B	dcbst	Data Cache Block Store
X	31	63			P	931	E.PD	dcbstep	Data Cache Block Store by External PID

¹ See the key to the mode dependency and privilege columns on page 1324 and the key to the category column in Section 1.3.5 of Book I.

Mode Dependency and Privilege Abbreviations

Except as described below and in Section 1.10.3, “Effective Address Calculation”, in Book I, all instructions are independent of whether the processor is in 32-bit or 64-bit mode.

Key to Mode Dependency Column

Mode Dep. Description

CT	If the instruction tests the Count Register, it tests the low-order 32 bits in 32-bit mode and all 64 bits in 64-bit mode.
SR	The setting of status registers (such as XER and CR0) is mode-dependent.
32	The instruction can be executed only in 32-bit mode.
64	The instruction can be executed only in 64-bit mode.

Key to Privilege Column

Priv. Description

P	Denotes a privileged instruction.
O	Denotes an instruction that is treated as privileged or nonprivileged (or hypervisor, for <i>mtspr</i>), depending on the SPR or PMR number.
H	Denotes an instruction that can be executed only in hypervisor state <S,E.HV>
M	Denotes an instruction that is treated as privileged or nonprivileged, depending on the value of the UCLE bit in the MSR.
