Preface

The roots of the Power ISA (Instruction Set Architecture) extend back 30 years, to IBM Research. The POWER (Performance Optimization With Enhanced RISC) Architecture was introduced with the RISC System/6000 product family in early 1990. In 1991, Apple, IBM, and Motorola began the collaboration to evolve to the PowerPC Architecture, expanding the architecture’s applicability. In 1997, Motorola and IBM began another collaboration, focused on optimizing PowerPC for embedded systems, which produced Book E.

In 2006, Freescale and IBM collaborated on the creation of the Power ISA Version 2.03, which represented the reunification of the architecture by combining Book E content with the more general purpose PowerPC Version 2.02. The resulting architecture included environment-specific privileged architecture optimizations (two Book IIIs) and optional application-specific facilities (categories) as extensions to a pervasive base architecture.

In support of the OpenPOWER Foundation’s standardization of server architecture, Power ISA Version 3.0 streamlined this integration by choosing a single Book III and a set of widely used categories to become part of the base architecture for all forward-looking Power implementations. All other optional architecture categories were eliminated to ensure increased application portability between Power processors. Legacy embedded applications that require the eliminated material will continue to use V. 2.07B.

Power ISA Version 3.0C took the first step in reintroducing optionality into the architecture as the Power ISA moves to an “open” model governed by the OpenPOWER Foundation. Material later in the preface identifies compliancy subsets of the architecture and the optional features which they comprise.

The Power ISA Version 3.1 consists of three books and a set of appendices.

Book I, Power ISA User Instruction Set Architecture, covers the base instruction set and related facilities available to the application programmer.

Book II, Power ISA Virtual Environment Architecture, defines the storage model and other instructions and facilities that enable the application programmer to create multithreaded programs and programs that interact with certain physical realities of the computing environment.

Book III, Power ISA Operating Environment Architecture, defines the supervisor instructions and related facilities.

As used in this document, the term “Power ISA” refers to the instructions and facilities described in Books I, II, and III.

Change bars have been included in the body of this document to indicate changes from the Power ISA Version 3.0C.
Summary of Changes in Power ISA Version 3.1

This document is Version 3.1 of the Power ISA. It is intended to supersede and replace version 3.0C. Any product descriptions that reference a version of the architecture are understood to reference the latest version. This version was created by making miscellaneous corrections and by applying the following requests for change (RFCs) to Power ISA Version 3.0C. Change bars in this summary of changes indicate changes relative to v3.0C.

**Byte-Reverse Instructions:**
Added new GPR-based byte-reverse instructions.

**Vector Integer Multiply/Divide/Modulo Instructions:**
Added SIMD-equivalent forms of FXU multiply, divide, and modulo instructions to increase synergy with FXU instruction set for auto-vectorization.

**Instruction Prefix Support:**
Added a 32-bit instruction prefix to support PC-relative addressing, up to 34-bit immediate operands, additional operand fields, and additional opcode space.

**BHRB Filtering:**
Added new BHRB Filtering fields and defined associated terminology.

**VSX 32-byte Storage Access Operations:**
Added new 32-byte VSR load and store instructions.

**Multiple DEAW:**
Added a second Data Address Watchpoint. [H]DAR is set to the first byte of overlap. 512B boundary is removed. Match detection is on DW granularity independent of operand size. SIAR/SDAR are not altered by the Trace interrupt when TE=0b00.

**128-bit Binary Integer Operations:**
Added new 128-bit integer instructions for comparison, divide, modulo, rotate, shift, DFP and QFP format conversion operations. Also added 128-bit integer multiply assist operations.

**SIMD Permute-Class Operations:**
New permute-class instructions for element extraction and insertion operations, 32-bit immediate splat operations, doublewide bit shift left/right operations, element mask-based blend operations, and an arbitrary-wide permute assist operation.

**Reduced-Precision: Outer Product Operations:**
Added new outer-product instructions to accelerate matrix multiplication, supporting 4-bit, 8-bit, and 16-bit integer and 16-bit, 32-bit, and 64-bit floating-point data types.

**Bit-Manipulation Operations:**
Added new bit-manipulation instructions.

**Set Boolean Extension:**
Added four new instructions that convert a condition code bit (any CR bit) into a Boolean (0/1), the negation of a Boolean (1/0), a field mask (all 0s/all 1s), and the negation of a field mask (all 1s/all 0s) that is placed into a GPR.

**String Operations:**
Added new string isolate instructions to support null-terminated and explicit-length strings.

**Test LSB by Byte Operation:**
Added new instruction to set any CR field to reflect predicate compare summary status, not just CR field 6 which Rc=1 is limited to.

**VSX Load/Store Rightmost Element Operations:**
Added new load and store instructions that transfer the rightmost vector element between VSR and storage.

**Prefixed addi Instruction and Prefixed Load/Store Instructions and Addressing:**
Using new instruction prefix, added support for extended immediate displacements and PC-relative addressing for a specific set of GPR and VSR load and store operations.

**VSX Scalar Minimum/Maximum/Compare Quad-Precision Operations:**
Add new quad-precision minimum, maximum, and predicate comparison instructions.

**CMODX Extension for Prefix:**
The quasi patch class of unsynchronized updates to instruction storage is made architecture. Language is changed and rules are added to account for the addition of prefixed instructions to the architecture.

**Reduced-Precision - bfloat16 Outer Product & Format Conversion Operations:**
Added new instructions to accelerate matrix multiplication and format conversions for the bfloat16 datatype.

**Processor Control Register Extensions:**
The PCR is updated to accommodate new problem-state instructions added in v3.1.

**Reduced-Precision: Missing Integer-based Outer Product Operations:**
Added additional new instructions to accelerate matrix multiplication for 8-bit and 16-bit integer datatypes.

**VSX Mask Manipulation Operations:**
Added new vector instructions to manipulate vector masks.

**VSX PCV Generate Operations:**
Added new permute control vector generate instructions to support efficient emulation of load expand and store compress operations.
New Performance Monitor SPRs:
Added three new performance monitor SPRs. SIER2 and SIER3 are added to provide additional information about the sampled instruction. MMCR3 is added for further sampling related configuration control.

Translation Management Extensions:
Added an L bit for sliag, where L=1 indicates an invalidation by LPID. tbiel with SET=0 and IS=1, 2, or 3 invalidate all congruence classes and tbiel with SET !=0 is a noop except when RIC=1, which becomes an invalid form. Made ISL apply in hypervisor state.

Copy/Paste Extensions:
Added memory move functionality.

Persistent Storage / Store Sync:
Added pushes and synchronization for persistent storage and variants of sync optimized for store ordering.

Pause / Wait-reserve:
Added two new variants of the wait instruction; removed platform notify, TIDR, and CIR.

Performance Monitor Facility Sampling Security:
Changes the definition of MMCR0_{PMCC=0b00} case to allow for a new secure mode of access with regards to sampling registers which is available conditional on new MMCR_{PMCCEXT} bit. Introduces a new freeze mode for ultravisor privilege state differentiating it from hypervisor privilege state freeze mode. Restricts BHRB to only record in problem state. Also MMCR0_{PMAQ}, bit 52 of MMCR0 is removed.

Hypervisor Interrupt Location Control:
Added HAIL for the hypervisor to specify its interrupt behavior independent from guest state.

Changes and Clarifications to Data Cache Management Instructions:
Specifies the that the number of software data prefetch streams guaranteed to be available to a thread varies by degree of multithreading in the processor. Clarifies when a new software data prefetch stream will overwrite an existing one. Redefines when a thread’s software data prefetch streams are cleared.

BHRB Disable Control:
Adds an additional control on BHRB recording via MMCRA bit 26 namely MMCRA_{BHRBRD}.
OpenISA Compliancy Subset Methodology and Requirements

The PowerISA comprises the base architecture (that which is never optional - not part of any optional or deprecated feature), four groups of optional features, and a group of deprecated features. (See the next two pages.) Authorized implementations of the Power ISA must support one of the four Compliancy Subsets defined below. Support of a subset means that a design includes the base architecture and all features that are not optional for that subset. A supporting design may also include any features that are optional for the supported subset (including deprecated features), subject to stated pre-requisites, and Custom Extensions created using the architecture sandbox defined below. “Inclusion” of the base architecture, of an optional feature, or of a custom extension can be accomplished using a combination of hardware and firmware, provided that the firmware is implemented using other elements of the base architecture and of the included features, and elements of the architecture sandbox; invoked using the second and third pages of real storage (see the second bullet of Section 6.7.5 of Book III); and subject to the prohibitions against the use of firmware given in Section 7.4.4 of Book III. Each optional or deprecated feature must be implemented in its entirety. Attempted execution of an instruction associated with a feature that is not included must cause a Hypervisor Emulation Assistance Interrupt (HEAI). The result of an attempted access to an SPR associated with a feature that is not included using mtspr or mfspr must be that described for “an SPR number that is undefined for the implementation” in the respective instruction description. See Section 5.4.4 of Book III. For Scalar Fixed-Point + Floating-Point and Scalar Fixed-Point Compliancy Subset implementations that do not include the logical partitioning feature, an Illegal Instruction type Program Interrupt as described in the penultimate Programming Note in Section 7.5.9 of Book III may be substituted for the HEAI.

OpenPOWER Compliancy Subsets

1. **AIX Compliancy Subset (ACS)**
   - The following features are optional for this compliancy subset. The rest of PowerISA v3.1 must be included.
     - Always Optional Features listed below
     - Deprecated Features listed below

2. **Linux Compliancy Subset (LCS)**
   - The following features are optional for this compliancy subset. The rest of PowerISA v3.1 must be included.
     - Linux Optional Features listed below
     - Always Optional Features listed below
     - Deprecated Features listed below

3. **Scalar Fixed-Point + Floating-Point Compliancy Subset (SFFS)**
   - The following features are optional for this compliancy subset. The rest of PowerISA v3.1 must be included.
     - Scalar Float Optional Features listed below
     - Linux Optional Features listed below
     - Always Optional Features listed below
     - Deprecated Features listed below

4. **Scalar Fixed-Point Compliancy Subset (SFS)**
   - The following features are optional for this compliancy subset. The rest of PowerISA v3.1 must be included.
     - Scalar Fixed Optional Features listed below
     - Scalar Float Optional Features listed below
     - Linux Optional Features listed below
     - Always Optional Features listed below
     - Deprecated Features listed below
OpenPOWER Optional and Deprecated Features

Always Optional Features

The following features are optional for all compliancy subsets.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Copy/Paste for accelerator invocation and memory copy (CPA)</td>
<td>See Section 4.4 of Book II.</td>
</tr>
<tr>
<td>Secure Memory Facility (SMF)¹</td>
<td>See Chapter 3 of Book III.</td>
</tr>
<tr>
<td>Hardware and software data stream prefetching (STM) (DSCR state not optional)</td>
<td>See Section 4.2 and Section 4.3.2 of Book II.</td>
</tr>
<tr>
<td>M=0 (M) (non-coherent memory)</td>
<td>See Section 1.6.3 of Book II.</td>
</tr>
<tr>
<td>W=1 (W) (write through-required memory)</td>
<td>See Section 1.6.1 of Book II.</td>
</tr>
<tr>
<td>Power management (PM)²</td>
<td>See Section 4.2.2, Section 4.3.2, and the description of the PECE field(s) of the LPCR in Section 2.2 of Book III.</td>
</tr>
<tr>
<td>MMA³</td>
<td>See Section 7.2.1.3 and Section 7.6.1.12 of Book I.</td>
</tr>
</tbody>
</table>

Notes:

1. LPAR is a pre-requisite for SMF.
2. If Power management is implemented by an ACS- or LCS-compliant design, it must be implemented as the architecture describes. If Power management is implemented by an SFFS- or SFS-compliant design, it need not be implemented as the architecture describes, and may include different interfaces created from the architecture sandbox.
3. SIMD is a requirement for MMA.
Linux Optional Features

The following features are optional for the Linux Compliancy Subset, the Scalar Fixed-Point + Floating-Point Compliancy Subset, and the Scalar Fixed-Point Compliancy Subset.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>AIL/HAIL programmability (AIL) (AIL=3 and HAIL=1 required)</td>
<td>See the description of the AIL and HAIL fields of the LPCR in Section 2.2 of Book III.</td>
</tr>
<tr>
<td>Atomic Memory Operations (AMO)</td>
<td>See Section 4.5 of Book II.</td>
</tr>
<tr>
<td>Big Endian (BE) (LE is required for LCS. Linux supporting LCS is 64b LE Linux.)</td>
<td>See Section 1.10 of Book I and its first two subsections. Also see the description of the ILE field of the LPCR in Section 2.2 of Book III and the description of the LE bit of the MSR in Section 4.2.1 of Book III.</td>
</tr>
<tr>
<td>Branch History Rolling Buffer (BHRB)</td>
<td>See Chapter 7 of Book II.</td>
</tr>
<tr>
<td>Decimal floating-point (DFP)¹</td>
<td>See Chapter 5 of Book I.</td>
</tr>
<tr>
<td>Event-Based Branching (EBB)</td>
<td>See Chapter 6 of Book II.</td>
</tr>
<tr>
<td>EVlRT programmability (EVlRT)² (EVlRT=1 required)</td>
<td>See the description of the EVlRT field of the LPCR in Section 2.2 of Book III.</td>
</tr>
<tr>
<td>SLB / HPT translation (HPT) (includes VPM, ISL, KBV)</td>
<td>See Section 6.7.7 through Section 6.7.9 of Book III. Also see the description of the VPM, ISL, and KBV fields of the LPCR in Section 2.2 of Book III.</td>
</tr>
<tr>
<td>Load/Store Multiple instructions (LM)</td>
<td>See Section 3.3.6 of Book I.</td>
</tr>
<tr>
<td>Load/Store String instructions (LS)</td>
<td>See Section 3.3.7 of Book I.</td>
</tr>
<tr>
<td>Processor Compatibility Register (PCR)²</td>
<td>See Section 2.5 of Book III.</td>
</tr>
<tr>
<td>Quad-precision floating-point (QFP)³</td>
<td>See Chapter 7 of Book I.</td>
</tr>
<tr>
<td>Broadcast TLB shootdown (TLBIE) (tlbiel not optional)</td>
<td>See Section 6.9.3.3 of Book III.</td>
</tr>
<tr>
<td>Control Register (CTRL)</td>
<td>See Section 5.3.4 of Book III.</td>
</tr>
<tr>
<td>SMT (SMT)⁴ (includes PURR/SPURR, PSPB, RPR, PPR, processor control) (PPR and hypervisor/ultrvisor messaging not optional)</td>
<td>See Chapter 3 of Book II. Also see Section 5.3.5 through Section 5.3.7, Section 8.6, Section 8.7, and Chapter 11 of Book III.</td>
</tr>
</tbody>
</table>

Notes:

1. FP is a pre-requisite for DFP.
2. LPAR is a pre-requisite for EVlRT and PCR.
3. SIMD is a pre-requisite for QFP.
4. If SMT is implemented by an LCS-compliant design, it must be implemented as the architecture describes. If SMT is not implemented by an LCS-compliant design, the design must not except on PPR accesses and must implement msgsnd[], msgctl[], and msgsyc. If SMT is implemented by an SFFS- or SFS-compliant design, it need not be implemented as the architecture describes, and may include different interfaces created from the architecture sandbox.
Scalar Float Optional Features

The following features are optional for the Scalar Fixed-Point + Floating-Point Compliancy Subset and the Scalar Fixed-Point Compliancy Subset.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIMD (SIMD)(^1) (VMX and VSX)</td>
<td>See Chapter 6 and Chapter 7 of Book I.</td>
</tr>
<tr>
<td>SF=1 (64-bit)(^2)</td>
<td>See Section 1.5 and Section 1.10.3 of Book I and the description of the SF field of the MSR in Section 4.2.1 of Book III.</td>
</tr>
<tr>
<td>Little Endian (LE) (BE is required for SFFS and SFS. Linux supporting SFFS and SFS is 32b BE Linux.)</td>
<td>See Section 1.10 of Book I and its first two subsections. Also see the description of the ILE field of the LPCR in Section 2.2 of Book III and the description of the LE bit of the MSR in Section 4.2.1 of Book III.</td>
</tr>
<tr>
<td>Logical partitioning (LPAR)(^3)(^4)</td>
<td>See Chapter 2 of Book III.</td>
</tr>
<tr>
<td>Fixed-point instructions that modify OV to indicate whether overflow occurred (OV) (addex and instructions with OE=1 such as addo, subfo, etc.)</td>
<td>See Section 3.3.9 of Book I.</td>
</tr>
<tr>
<td>Nested radix translation (ROR)(^5) (single-level radix translation not optional)</td>
<td>See Section 6.7.7 and Section 6.7.10 of Book III.</td>
</tr>
</tbody>
</table>

Notes:
1. FP is a pre-requisite for SIMD.
2. When 64-bit is not included, a single radix tree will be used to map both application and OS address spaces (no quadrant structure).
3. 64-bit is a pre-requisite for LPAR.
4. When LPAR is not included, MSRHV=1 always.
5. LPAR is a pre-requisite for ROR.

Scalar Fixed Optional Features

The following features are optional for the Scalar Fixed-Point Compliancy Subset

<table>
<thead>
<tr>
<th>Feature</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scalar binary floating-point (FP)</td>
<td>See Chapter 4 of Book I.</td>
</tr>
</tbody>
</table>

Deprecated Features

There are no deprecated features in Power ISA v3.1.
OpenPOWER Architecture Sandbox

OpenPOWER compliance subsets permit Custom Extensions. Any architectural resources used for Custom Extensions must use only the resources described below and any instructions and SPRs that the architecture describes as implementation-dependent.

Development of Custom Extensions using the architecture sandbox is appropriate for facilities that benefit a small portion of the processor design space. For facilities with broad applicability, developers are strongly encouraged to submit a proposal for adoption into the architecture. Adopted proposals will become optional or required features of the architecture, and will be assigned resources that are not in the architecture sandbox to avoid fragmentation of the architecture. Facilities described in proposals that are not adopted into the architecture may be implemented as Custom Extensions using the architecture sandbox.

System software and toolchain support of Custom Extensions is not guaranteed. Developers are encouraged to provide a means to disable custom extensions to present an architecture that is supported by standard system software and toolchain.

The architecture sandbox consists of the following.
- The designated opcode sandbox is instructions having a primary opcode of 22. Note that primary opcode 22 is reserved by AIX. As a result, Custom Extensions that use primary opcode 22 are not compatible with ACS.
- The designated SPR sandbox consists of non-privileged SPRs 704-719 and privileged SPRs 720-735.
- The designated [H]FSCR sandbox consists of [H]FSCR bits 8-9 and their corresponding IC values.
- The designated XER bit sandbox consists of XER bits 54:55.
- The designated FPSCR bit sandbox consists of FPSCR bits 14-15.
- The designated VSCR bit sandbox consists of VSCR bits 96 & 112. VSCR bit 96 is provided for Vector Facility control & VSCR bit 112 is provided for Vector Facility status.
- The designated interrupt vector sandbox consists of interrupt vector 0x0000_0000_0000_0FE0.

Chapter 7. Vector-Scalar Extension Facility

7.1 Introduction
7.1.1 Overview of the Vector-Scalar Extension
7.1.1.1 Combining the Floating-Point Registers (FPR) defined in Chapter 4. Floating-Point Facility and the Vector Registers (VR) defined in Chapter 6. Vector Facility provides additional registers to support more aggressive compiler optimizations for both vector and scalar operations. Compatibility with Floating-Point and Decimal Floating-Point Operations
7.1.1.2 Compatibility with Vector Operations
7.2 VSX Registers
7.2.1 Vector-Scalar Registers
7.2.1.1 Floating-Point Registers
7.2.1.2 Vector Registers
7.2.1.3 VSX Accumulators
7.2.2 Floating-Point Status and Control Register
7.3 VSX Operations

7.3.1 VSX Floating-Point Arithmetic Overview
7.3.2 VSX Floating-Point Data
7.3.2.1 Data Format
7.3.2.2 Value Representation
7.3.2.3 Sign of Result
7.3.2.4 Normalization and Denormalization
7.3.2.5 Data Handling and Precision
7.3.2.6 Rounding
7.3.3 VSX Floating-Point Execution Models
7.3.3.1 VSX Execution Model for IEEE Operations
7.3.3.2 VSX Execution Model for Multiply-Add Type Instructions
7.4 VSX Floating-Point Exceptions
7.4.1 Floating-Point Exceptions
7.4.1.1 Definition
7.4.1.2 Action for VE=1
7.4.1.3 Action for VE=0
7.4.2 Floating-Point Zero Divide Exception
7.4.2.1 Definition
7.4.2.2 Action for ZE=1
7.4.2.3 Action for ZE=0
7.4.3 Floating-Point Overflow Exception
7.4.3.1 Definition
7.4.3.2 Action for OE=1
7.4.3.3 Action for OE=0
7.4.4 Floating-Point Underflow Exception
7.4.4.1 Definition
7.4.4.2 Action for UE=1
7.4.4.3 Action for UE=0
7.4.5 Floating-Point Inexact Exception
7.4.5.1 Definition
7.4.5.2 Action for XE=1
7.4.5.3 Action for XE=0
7.5 VSX Storage Access Operations
7.5.1 Accessing Aligned Storage Operations
7.5.2 Accessing Unaligned Storage Operations
7.5.3 Storage Access Exceptions
7.6 VSX Instruction Set
7.6.1 VSX Instruction Set Summary
7.6.1.1 VSX Storage Access Instructions
7.6.1.2 VSX Binary Floating-Point Sign Manipulation Instructions
7.6.1.3 VSX Binary Floating-Point Arithmetic Instructions
7.6.1.4 VSX Binary Floating-Point Compare Instructions .................. 570
7.6.1.5 VSX Binary Floating-Point Round to Shorter Precision Instructions .... 571
7.6.1.6 VSX Binary Floating-Point Convert to Shorter Precision Instructions .... 571
7.6.1.7 VSX Binary Floating-Point Convert to Longer Precision Instructions .... 571
7.6.1.8 VSX Binary Floating-Point Round to Integral Instructions ............. 572
7.6.1.9 VSX Binary Floating-Point Convert to Integer Instructions ............ 572
7.6.1.10 VSX Binary Floating-Point Convert From Integer Instructions ......... 573
7.6.1.11 VSX Binary Floating-Point Math Support Instructions ................ 573
7.6.1.12 VSX Matrix-Multiply Assist (MMA) Instructions ...................... 574
7.6.1.12.1 VSX Accumulator Move Instructions ................................ 574
7.6.1.12.2 VSX Binary Integer Outer-Product Instructions .................... 574
7.6.1.12.3 VSX Binary Floating-Point Outer-Product Instructions .............. 575
7.6.1.13 VSX Vector Logical Instructions ...................................... 576
7.6.1.14 VSX Vector Permute-class Instructions ................................ 577
7.6.1.15 VSX Vector Load Special Value Instruction ............................ 578
7.6.1.16 VSX Vector Test Least-Significant Bit by Byte Instruction ............ 578
7.6.2 VSX Instruction Description Conventions ................................ 579
7.6.2.1 VSX Instruction RTL Operators 579
7.6.2.2 VSX Instruction RTL Function Calls .................................. 580
7.6.3 VSX Instruction Descriptions .............................................. 580

Appendix A. Suggested Floating-Point Models ......................... 995
A.1 Floating-Point Round to Single-Precision Model ...................... 995
A.2 Floating-Point Convert to Integer Model ............................... 999
A.3 Floating-Point Convert from Integer Model ......................... 1002
A.4 Floating-Point Round to Integer Model ............................... 1004

Appendix B. Densely Packed Decimal ................................. 1007
B.1 BCD-to-DPD Translation ................................................. 1007
B.2 DPD-to-BCD Translation ................................................. 1007
B.3 Preferred DPD encoding ................................................ 1008

Appendix C. Assembler Extended Mnemonics ...................... 1011
C.1 Symbols ................................................................. 1011
C.2 Branch Mnemonics ..................................................... 1012
C.2.1 BO and BI Fields .................................................. 1012
C.2.2 Simple Branch Mnemonics ........................................ 1012
C.2.3 Branch Mnemonics Incorporating Conditions ...................... 1013
C.2.4 Branch Prediction .................................................. 1014
C.3 Condition Register Logical Mnemonics ............................ 1015
C.4 Subtract Mnemonics ................................................... 1015
C.4.1 Subtract Immediate ................................................ 1015
C.4.2 Subtract ........................................................... 1015
C.5 Compare Mnemonics .................................................. 1016
C.5.1 Doubleword Comparisons ........................................ 1016
C.5.2 Word Comparisons ................................................ 1016
C.6 Trap Mnemonics ......................................................... 1017
C.7 Integer Select Mnemonics ............................................ 1018
C.8 Rotate and Shift Mnemonics ......................................... 1019
C.8.1 Operations on Doublewords ....................................... 1019
C.8.2 Operations on Words ............................................... 1020
C.9 Move To/From Special Purpose Register Mnemonics ............. 1021
C.10 Miscellaneous Mnemonics ........................................... 1022

Book II:

Power ISA Virtual Environment Architecture .................... 1027

Chapter 1. Storage Model ............................................. 1029
1.1 Definitions .......................................................... 1029
1.2 Introduction ........................................................ 1030
1.3 Virtual Storage ....................................................... 1031
1.4 Single-Copy Atomicity ............................................. 1031
1.5 Cache Model ........................................................ 1032
1.6 Storage Control Attributes ..................................... 1032
1.6.1 Write Through Required .......................................... 1033
1.6.2 Caching Inhibited ................................................ 1033
1.6.3 Memory Coherence Required .................................... 1033
1.6.4 Guarded ........................................................... 1034
1.7 Shared Storage ....................................................... 1034
1.7.1 Storage Access Ordering ......................................... 1034
1.7.1.1 Storage Ordering of Copy/Paste-Initiated Data Transfers ........ 1034
1.7.1.2 Storage Ordering of Stores to Persistent Storage ........... 1037
1.7.1.3 Storage Ordering of I/O Accesses ............................. 1038
1.7.2 Atomic Update ..................................................... 1038
1.7.2.1 Reservations .................................................. 1039
1.7.2.2 Forward Progress ............................................ 1040
1.8 Instruction Storage .................................................. 1041
Chapter 2. Instruction Restart. 1045

Chapter 3. Management of Shared Resources 1047
  3.1 Program Priority Registers 1047
  3.2 "or" Instruction 1048

Chapter 4. Storage Control Instructions 1049
  4.1 Parameters Useful to Application Programs 1049
  4.2 Data Stream Control Register (DSCR) 1049
  4.3 Cache Management Instructions 1051
  4.3.1 Instruction Cache Instructions 1052
  4.3.2 Data Cache Instructions 1053
  4.3.2.1 Obsolete Data Cache Instructions 1065
  4.3.3 "or" Instruction 1066
  4.4 Copy-Paste Facility 1067
  4.5 Atomic Memory Operations 1070
  4.5.1 Load Atomic 1070
  4.5.2 Store Atomic 1074
  4.6 Synchronization Instructions 1076
  4.6.1 Instruction Synchronize Instruction 1076
  4.6.2 Load And Reserve and Store Conditional Instructions 1076
  4.6.2.1 64-Bit Load And Reserve and Store Conditional Instructions 1082
  4.6.2.2 128-bit Load And Reserve and Store Conditional Instructions 1084
  4.6.3 Memory Barrier Instructions 1086
  4.6.4 Wait Instruction 1090

Chapter 5. Time Base 1093
  5.1 Time Base Instructions 1094

Chapter 6. Event-Based Branch Facility 1097
  6.1 Event-Based Branch Overview 1097
  6.2 Event-Based Branch Registers 1097
  6.2.1 Branch Event Status and Control Register 1097
  6.2.2 Event-Based Branch Handler Register 1099
  6.2.3 Event-Based Branch Return Register 1099
  6.3 Event-Based Branch Instructions 1100

Chapter 7. Branch History Rolling Buffer 1101
  7.1 Branch History Rolling Buffer Entry Format 1102
  7.2 Branch History Rolling Buffer Instructions 1103

Appendix A. Assembler Extended Mnemonics 1105
  A.1 Data Cache Block Touch [for Store] Mnemonics 1105
  A.2 Data Cache Block Flush Mnemonics 1105
  A.3 Or Mnemonics 1105
  A.4 Load And Reserve Mnemonics 1105
  A.5 Synchronize Mnemonics 1106
  A.6 Wait Mnemonics 1106
  A.7 Move To/From Time Base Mnemonics 1106
  A.8 Return From Event-Based Branch Mnemonic 1106

Appendix B. Programming Examples for Sharing Storage 1107
  B.1 Atomic Update Primitives 1107
  B.2 Lock Acquisition and Release, and Related Techniques 1109
  B.2.1 Lock Acquisition and Import Barriers 1109
  B.2.1.1 Acquire Lock and Import Shared Storage 1109
  B.2.1.2 Obtain Pointer and Import Shared Storage 1109
  B.2.2 Lock Release and Export Barriers 1110
  B.2.2.1 Export Shared Storage and Release Lock 1110
  B.2.2.2 Export Shared Storage and Release Lock using lwsync 1110
  B.2.3 Safe Fetch 1110
  B.3 List Insertion 1111
  B.4 Notes 1111

Book III:

Power ISA Operating Environment Architecture 1113

Chapter 1. Introduction 1115
  1.1 Overview 1115
  1.2 Document Conventions 1115
  1.2.1 Definitions and Notation 1115
1.2.2 Reserved Fields ................. 1116
1.2.3 Deviations from the Sequential Execution Model ................. 1117
1.2.4 Restricting Out-of-Order Execution ................................ 1117
1.3 General Systems Overview .................. 1117
1.4 Exceptions .......................... 1117
1.5 Synchronization ...................... 1118
1.5.1 Context Synchronization .......... 1118
1.5.2 Execution Synchronization ...... 1119

Chapter 2. Logical Partitioning (LPAR) and Thread Control .... 1121
2.1 Overview ............................ 1121
2.2 Logical Partitioning Control Register (LPCCR) ....................... 1121
2.3 Hypervisor Real Mode Offset Register (HRMOR) ...................... 1126
2.4 Logical Partition Identification Register (LPIDR) .................... 1126
2.5 Processor Compatibility Register (PCR) .......................... 1126
2.6 Other Hypervisor Resources ........ 1136
2.7 Sharing Hypervisor and Ultravisor Resources .............. 1137
2.8 Sub-Processors ...................... 1137
2.9 Thread Identification Register (TIR) .......................... 1137
2.10 Hypervisor Interrupt Little-Endian (HILE) Bit .................. 1138

Chapter 3. Ultravisor and Secure Memory Facility (SMF) .... 1139
3.1 Overview ............................ 1139
3.2 Ultravisor Real Mode Offset Register (URMOR) ....................... 1140
3.3 Ultravisor Interrupt Little-Endian (UILE) Bit ...................... 1140
3.4 Secure Memory Facility Control Register (SMFCTRL) ................ 1140
3.4.1 Enabling SMF and Secure Memory Enforcement ................ 1141

Chapter 4. Branch Facility ......... 1143
4.1 Branch Facility Overview .................. 1143
4.2 Branch Facility Registers .............. 1143
4.2.1 Machine State Register .............. 1143
4.2.2 Processor Stop Status and Control Register (PSSCR) ........... 1147
4.3 Branch Facility Instructions ........... 1150
4.3.1 System Linkage Instructions ........ 1150
4.3.2 Power-Saving Mode ................ 1154
4.3.2.1 Power-Saving Mode Instruction .... 1155
4.3.2.2 Entering and Exiting Power-Saving Mode ................. 1155
4.4 Event-Based Branch Facility and Instruction .................... 1157

Chapter 5. Fixed-Point Facility .... 1159
5.1 Fixed-Point Facility Overview ........... 1159
5.2 Special Purpose Registers .............. 1159
5.3 Fixed-Point Facility Registers .......... 1159
5.3.1 Processor Version Register .......... 1159
5.3.2 Processor Identification Register .......... 1159
5.3.3 Process Identification Register ........ 1160
5.3.4 Control Register .................... 1160
5.3.5 Program Priority Register .......... 1160
5.3.6 Problem State Priority Boost Register .......... 1160
5.3.7 Relative Priority Register .......... 1161
5.3.8 Software-use SPRs .............. 1161
5.4 Fixed-Point Facility Instructions .... 1163
5.4.1 Fixed-Point Load and Store Caching Inhibited Instructions .......... 1163
5.4.2 OR Instruction .................... 1166
5.4.3 OR Immediate Instruction ............ 1166
5.4.4 Move To/From System Register Instructions .......... 1166

Chapter 6. Storage Control ......... 1177
6.1 Overview ............................ 1177
6.2 Storage Exceptions .............. 1177
6.3 Instruction Fetch ..................... 1177
6.3.1 Implicit Branch .............. 1177
6.3.2 Address Wrapping Combined with Changing MSR Bit SF .......... 1177
6.4 Data Access ..................... 1178
6.5 Performing Operations Out-of-Order .......... 1178
6.6 Invalid Real Address .......... 1178
6.7 Storage Addressing .......... 1179
6.7.1 32-Bit Mode .......... 1179
6.7.2 Virtualized Partition Memory (VPM) Mode .......... 1180
6.7.3 Ultravisor Real, Hypervisor Real, and Virtual Real Addressing Modes ........ 1180
6.7.3.1 Ultravisor/Hypervisor Offset Real Mode Address .......... 1180
6.7.3.2 Storage Control Attributes for Accesses in Ultravisor and Hypervisor Real Addressing Modes .......... 1181
6.7.3.2.1 Hypervisor Real Mode Storage Control .......... 1181
6.7.3.3 Virtual Real Mode Addressing Mechanism .......... 1182
6.7.3.4 Storage Control Attributes for Implicit Storage Accesses .......... 1183
6.7.4 Definitions ........................ 1183
6.7.5 Address Ranges Having Defined Uses ........................................ 1184

6.7.5.1 Effective Address Space Structure for Radix-using Partitions .... 1184

6.7.6 In-Memory Tables ..................................................... 1185

6.7.6.1 Partition Table .................................................... 1185

6.7.6.2 Process Table ..................................................... 1187

6.7.7 Address Translation Overview .................................... 1188

6.7.8 Segment Translation .................................................. 1190

6.7.8.1 Segment Lookaside Buffer (SLB) ................................. 1190

6.7.8.2 SLB Search ....................................................... 1192

6.7.8.3 Segment Table Description and Search ........................... 1192

6.7.8.3.1 Primary Hash for 256MB Segment .......................... 1192

6.7.8.3.2 Primary Hash for 1TB Segment ............................... 1192

6.7.8.3.3 Secondary Hash for 256MB Segment ....................... 1192

6.7.8.3.4 Secondary Hash for 1TB Segment ............................. 1193

6.7.9 Hashed Page Table Translation .................................. 1193

6.7.9.1 Hashed Page Table .................................................. 1195

6.7.9.2 Page Table Search ................................................ 1196

6.7.10 Radix Tree Translation .............................................. 1198

6.7.10.1 Radix Tree Page Directory Entry ............................... 1199

6.7.10.2 Radix Tree Page Table Entry .................................. 1200

6.7.10.3 Nested Translation .............................................. 1200

6.7.11 Translation Process .................................................. 1202

6.7.11.1 Fully-Qualified Address ........................................ 1202

6.7.11.2 Finding the Page Tables ...................................... 1202

6.7.11.3 Obtaining Host Real Address, Radix on Radix ............... 1203

6.7.11.4 Obtaining Host Real Address, HPT ............................... 1204

6.7.12 Reference and Change Recording .................................. 1204

6.7.13 Storage Protection ...................................................... 1208

6.7.13.1 Virtual Page Class Key Protection ............................. 1208

6.7.13.2 Basic Storage Protection, Address Translation Enabled .... 1212

6.7.13.3 Basic Storage Protection, Address Translation Disabled ..... 1213

6.7.13.4 Radix Tree Translation Storage Protection ....................... 1213

6.7.13.5 Secure Memory Protection ...................................... 1214

6.8 Storage Control Attributes ............................................. 1214

6.8.1 Guarded Storage ..................................................... 1215

6.8.1.1 Out-of-Order Accesses to Guarded Storage ....................... 1215

6.8.2 Storage Control Bits .................................................. 1215

6.8.2.1 Storage Control Bit Restrictions ................................. 1216

6.8.2.2 Altering the Storage Control Bits ............................... 1216

6.9 Storage Control Instructions .......................................... 1218

6.9.1 Cache Management Instructions ................................... 1218

6.9.2 Synchronize Instruction ............................................. 1218

6.9.3 Lookaside Buffer Management ..................................... 1219

6.9.3.1 Thread-Specific Segment Translations ......................... 1220

6.9.3.2 SLB Management Instructions ................................. 1220

6.9.3.3 TLB Management Instructions .................................. 1231

6.10 Translation Table Update Synchronization Requirements ............. 1241

6.10.1 Translation Table Updates ....................................... 1242

6.10.1.1 Adding a Page Table Entry ................................. 1243

6.10.1.2 Modifying a Translation Table Entry .......................... 1243

Chapter 7. Interrupts ...................................................... 1247

7.1 Overview ................................................................. 1247

7.2 Interrupt Registers .................................................... 1247

7.2.1 Machine Status Save/Restore Registers ........................... 1247

7.2.2 Hypervisor Machine Status Save/Restore Registers ............... 1247

Book I: Power ISA User Instruction Set Architecture
Chapter 1. Introduction

1.1 Overview
This chapter describes computation modes, document conventions, a processor overview, instruction formats, storage addressing, and instruction fetching.

1.2 Instruction Mnemonics and Operands
The description of each instruction includes the mnemonic and a formatted list of operands. Some examples are the following.

```
stw RS,D(RA)
addis RT,RA,SI
```
Power ISA-compliant Assemblers will support the mnemonics and operand lists exactly as shown. They should also provide certain extended mnemonics, such as the ones described either in Appendix C of Book I or in the instruction description, if extended mnemonics are provided for the instruction. Assemblers will support extended mnemonics having a reduced number of operands using the specified default values for any operands omitted from the base form.

1.3 Document Conventions

1.3.1 Definitions
The following definitions are used throughout this document.

- **program**
  A sequence of related instructions.

- **application program**
  A program that uses only the instructions and resources described in Books I and II.

- **processor**
  The hardware component that implements the instruction set, storage model, and other facilities defined in the Power ISA architecture, and executes the instructions specified in a program.

- **octword, quadword, doubleword, word, halfword, byte, and nibble**
  256 bits, 128 bits, 64 bits, 32 bits, 16 bits, 8 bits, and 4 bits, respectively.

- **positive**
  Means greater than zero.

- **negative**
  Means less than zero.

- **floating-point single format (or simply single format)**
  Refers to the representation of a single-precision binary floating-point value in a register or storage.

- **floating-point double format (or simply double format)**
  Refers to the representation of a double-precision binary floating-point value in a register or storage.

- **system library program**
  A component of the system software that can be called by an application program using a Branch instruction.

- **system service program**
  A component of the system software that can be called by an application program using a System Call or System Call Vectored instruction.

- **system trap handler**
  A component of the system software that receives control when the conditions specified in a Trap instruction are satisfied.

- **system error handler**
  A component of the system software that receives control when an error occurs. The system error handler includes a component for each of the various kinds of error. These error-specific components are referred to as the system alignment error handler, the system data storage error handler, etc.

- **latency**
  Refers to the interval from the time an instruction begins execution until it produces a result that is available for use by a subsequent instruction.
■ unavailable
  Refers to a resource that cannot be used by the program. For example, storage is unavailable if access to it is denied. See Book III.

■ undefined value
  May vary between implementations, and between different executions on the same implementation, and similarly for register contents, storage contents, etc., that are specified as being undefined.

■ boundedly undefined
  The results of executing a given instruction are said to be boundedly undefined if they could have been achieved by executing an arbitrary finite sequence of instructions (none of which yields boundedly undefined results) in the state the processor was in before executing the given instruction. Boundedly undefined results may include the presentation of inconsistent state to the system error handler as described in Section 1.8.1 of Book II. Boundedly undefined results for a given instruction may vary between implementations, and between different executions on the same implementation.

■ “must”
  If software violates a rule that is stated using the word “must” (e.g., “this field must be set to 0”), the results are boundedly undefined unless otherwise stated.

■ sequential execution model
  The model of program execution described in Section 2.2, “Instruction Execution Order” on page 33.

1.3.2 Notation

The following notation is used throughout the Power ISA documents.

■ All numbers are decimal unless specified in some special way.
  - 0bnnnn means a number expressed in binary format.
  - 0xnnnn means a number expressed in hexadecimal format.

Underscores may be used between digits.

■ RT, RA, R1, ... refer to General Purpose Registers.

■ FRT, FRA, FR1, ... refer to Floating-Point Registers.

■ FRTp, FRAp, FRBp, ... refer to an even-odd pair of Floating-Point Registers. Values must be even, otherwise the instruction form is invalid.

■ VRT, VRA, VR1, ... refer to Vector Registers.

■ (x) means the contents of register x, where x is the name of an instruction field. For example, (RA) means the contents of register RA, and (FRA) means the contents of register FRA, where RA and FRA are instruction fields. Names such as LR and CTR denote registers, not fields, so parentheses are not used with them. Parentheses are also omitted when register x is the register into which the result of an operation is placed.

■ (RA(0)) means the contents of register RA if the RA field has the value 1-31, or the value 0 if the RA field is 0.

■ Bytes in registers, instructions, fields, and bit strings are numbered from left to right, starting with byte 0 (most significant).

■ Bits in registers, instructions, fields, and bit strings are specified as follows. In the last three items (definition of $X_p$ etc.), if $X$ is a field that specifies a GPR, FPR, or VR (e.g., the RS field of an instruction), the definitions apply to the register, not to the field.
  - Bits in instructions, fields, and bit strings are numbered from left to right, starting with bit 0
  - For all registers except the Vector registers, bits in registers that are less than 64 bits start with bit number 64-L, where L is the register length; for the Vector registers, bits in registers that are less than 128 bits start with bit number 128-L.
  - The leftmost bit of a sequence of bits is the most significant bit of the sequence.
  - $X_p$ means bit $p$ of register/instruction/field/bit_string $X$.
  - $X_{p:q}$ means bits $p$ through $q$ of register/instruction/field/bit_string $X$.
  - $X_{p\ q\ ...}$ means bits $p$, $q$, ... of register/instruction/field/bit_string $X$.

■ ¬(RA) means the one’s complement of the contents of register RA.

■ A period (.) as the last character of an instruction mnemonic means that the instruction records status information in certain fields of the Condition Register as a side effect of execution.

■ The symbol || is used to describe the concatenation of two values. For example, 010 || 111 is the same as 010111.

■ $x^n$ means $x$ raised to the $n$th power.

■ $x^n$ means the replication of $x$, $n$ times (i.e., $x$ concatenated to itself $n$-1 times). $n^0$ and $n^1$ are special cases:
  - $n^0$ means a field of $n$ bits with each bit equal to 0. Thus $5^0$ is equivalent to 0b00000.
  - $n^1$ means a field of $n$ bits with each bit equal to 1. Thus $5^1$ is equivalent to 0b11111.

■ Each bit and field in instructions, and in status and control registers (e.g., XER, FPSCR) and Special
1.3.3 Reserved Fields, Reserved Values, and Reserved SPRs

Reserved fields in instructions are ignored by the processor.

In some cases a defined field of an instruction has certain values that are reserved. This includes cases in which the field is shown in the instruction layout as containing a particular value; in such cases all other values of the field are reserved. In general, if an instruction is coded such that a defined field contains a reserved value the instruction form is invalid; see Section 1.8.2 on page 24. The only exception to the preceding rule is that it does not apply to Reserved and Illegal classes of instructions (see Section 1.6.3) or to portions of defined fields that are specified, in the instruction description, as being treated as reserved fields.

To maximize compatibility with future architecture extensions, software must ensure that reserved fields in instructions contain zero and that defined fields of instructions do not contain reserved values.

The handling of reserved bits in System Registers (e.g., XER, FPSCR) depends on whether the processor is in problem state. Unless otherwise stated, software is permitted to write any value to such a bit. In problem state, a subsequent reading of the bit returns 0 regardless of the value written; in privileged states, a subsequent reading of the bit returns 0 if the value last written to the bit was 0 and returns an undefined value (0 or 1) otherwise.

In some cases, a defined field of a System Register has certain values that are reserved. Software must not set a defined field of a System Register to a reserved value. References elsewhere in this document to a defined field (in an instruction or System Register) that has reserved values assume the field does not contain a reserved value, unless otherwise stated or obvious from context.

In some cases, a given bit of a System Register is specified to be set to a constant value by a given instruction or event. Unless otherwise stated or obvious from context, software should not depend on this constant value because the bit may be assigned a meaning in a future version of the architecture.

The reserved SPRs include SPRs 808, 809, 810, and 811. \texttt{mtspr} and \texttt{mfspr} instructions specifying these SPRs are treated as no-ops. Reserved SPRs are provided in the architecture to anticipate the eventual adoption of performance hint functionality that must be controlled by SPRs. Control of these capabilities using reserved SPRs will allow software to use these new capabilities on new implementations that support them while remaining compatible with existing implementations that may not support the new functionality.
Reserved SPRs are not assigned names. There are no individual descriptions of reserved SPRs in this document.

**Assembler Note**

Assemblers should report uses of reserved values of defined fields of instructions as errors.

**Programming Note**

It is the responsibility of software to preserve bits that are now reserved in System Registers, because they may be assigned a meaning in some future version of the architecture.

In order to accomplish this preservation in implementation-independent fashion, software should do the following.

- Initialize each such register supplying zeros for all reserved bits.
- Alter (defined) bit(s) in the register by reading the register, altering only the desired bit(s), and then writing the new value back to the register.

The XER and FPSCR are partial exceptions to this recommendation. Software can alter the status bits in these registers, preserving the reserved bits, by executing instructions that have the side effect of altering the status bits. Similarly, software can alter any defined bit in the FPSCR by executing a Floating-Point Status and Control Register instruction. Using such instructions is likely to yield better performance than using the method described in the second item above.

### 1.3.4 Description of Instruction Operation

Instruction descriptions (including related material such as the introduction to the section describing the instructions) mention that the instruction may cause a system error handler to be invoked, under certain conditions, if and only if the system error handler may treat the case as a programming error. (An instruction may cause a system error handler to be invoked under other conditions as well; see Chapter 7 of Book III).

A formal description is given of the operation of each instruction. In addition, the operation of most instructions is described by a semiformal language at the register transfer level (RTL). This RTL uses the notation given below, in addition to the notation described in Section 1.3.2. Some of this notation is also used in the formal descriptions of instructions. RTL notation not summarized here should be self-explanatory.

The RTL descriptions cover the normal execution of the instruction, except that “standard” setting of status registers, such as the Condition Register, is not shown. (“Non-standard” setting of these registers, such as the setting of the Condition Register by the Compare instructions, is shown.) The RTL descriptions do not cover cases in which the system error handler is invoked, or for which the results are boundedly undefined.

The RTL descriptions specify the architectural transformation performed by the execution of an instruction. They do not imply any particular implementation.

#### Notation Meaning

- Assignment
- Assignment of an instruction effective address. In 32-bit mode the high-order 32 bits of the 64-bit target address are set to 0.
- NOT logical operator
- Two’s complement addition
- Two’s complement subtraction, unary minus
- Multiplication
- Signed-integer multiplication
- Unsigned-integer multiplication
- Division
- Division, with result truncated to integer
- Remainder of integer division
- Square root
- Equals, Not Equals relations
- Signed comparison relations
- Unsigned comparison relations
- Unordered comparison relation
- AND, OR logical operators
- Exclusive OR, Equivalence logical operators

#### ABS(x)
Absolute value of x

#### BCD_TO_DPD(x)
The low-order 24 bits of x contain six, 4-bit BCD fields which are converted to two declets; each set of two declets is placed into the low-order 20 bits of the result. See Section B.1, “BCD-to-DPD Translation”.

#### CEIL(x)
Least integer \( \geq x \)

#### DOUBLE(x)
Result of converting x from floating-point single format to floating-point double format, using the model shown on page 149

#### DPD_TO_BCD(x)
The low-order 20 bits of x contain two declets which are converted to six, 4-bit BCD fields; each set of six, 4-bit BCD fields is placed into the low-order 24 bits of the result. See Section B.2, “DPD-to-BCD Translation”.

#### EXTS(x)
Result of extending x on the left with sign bits

#### FLOOR(x)
Greatest integer \( \leq x \)

#### GPR(x)
General Purpose Register x

#### MASK(x, y)
Mask having 1s in positions x through y (wrapping if \( x > y \)) and 0s elsewhere

Assemblers should report uses of reserved values of defined fields of instructions as errors.
MEM(x, y) Contents of a sequence of y bytes of storage. The sequence depends on the byte ordering used for storage access, as follows.

Big-Endian byte ordering:
The sequence starts with the byte at address x and ends with the byte at address x+y-1.

Little-Endian byte ordering:
The sequence starts with the byte at address x+y-1 and ends with the byte at address x.

MEM\text{metadata}(x,y) Metadata associated with MEM(x,y).

ROTL_{64}(x, y) Result of rotating the 64-bit value x left y positions

ROTL_{32}(x, y) Result of rotating the 64-bit value x|x left y positions, where x is 32 bits long

SINGLE(x) Result of converting x from floating-point double format to floating-point single format, using the model shown on page 154

SPR(x) Special Purpose Register x

TRAP Invoke the system trap handler

Characterization
Reference to the setting of status bits, in a standard way that is explained in the text

undefined An undefined value.

CIA Current Instruction Address, which is the 64-bit address of the instruction being described by a sequence of RTL. Used by relative branches to set the Next Instruction Address (NIA), and by Branch instructions with LK=1 to set the Link Register.

NIA Next Instruction Address, which is the 64-bit address of the next instruction to be executed. For a successful branch, the next instruction address is the branch target address: in RTL, this is indicated by assigning a value to NIA. For other instructions that cause non-sequential instruction fetching (see Book III), the RTL is similar.

For instructions that do not branch, and do not otherwise cause instruction fetching to be non-sequential, the next instruction address is CIA+4. Does not correspond to any architected register.

if... then... else... Conditional execution, indenting shows range; else is optional.

do Do loop, indenting shows range. “To” and/or “by” clauses specify incrementing an iteration variable, and a “while” clause gives termination conditions.

leave Leave innermost do loop, or do loop described in leave statement.
The precedence rules for RTL operators are summarized in Table 1. Operators higher in the table are applied before those lower in the table. Operators at the same level in the table associate from left to right, from right to left, or not at all, as shown. (For example, $-\cdot$ associates from left to right, so $a-b-c = (a-b)-c$.) Parentheses are used to override the evaluation order implied by the table or to increase clarity; parenthesized expressions are evaluated before serving as operands.

### 1.3.5 Phased-Out Facilities

#### Phased-Out Facilities

These are facilities and instructions that, in some future version of the architecture, will be dropped out of the architecture. System developers should develop a migration plan to eliminate use of them in new systems. These facilities are marked with a [Phased-Out] marker.

Phased-Out facilities and instructions must be implemented.

---

**Warning:** Instructions and facilities being phased out of the architecture are likely to perform poorly on future implementations. New programs should not use them.
1.4 Processor Overview

The basic classes of instructions are as follows:

- branch instructions (Chapter 2)
- GPR-based scalar fixed-point instructions (Chapter 3)
- FPR-based scalar floating-point instructions (Chapter 4)
- FPR-based scalar decimal floating-point instructions (Chapter 5)
- VR-based vector fixed-point and floating-point instructions (Chapter 6)
- VSR-based scalar and vector floating-point instructions (Chapter 7)

Scalar fixed-point instructions operate on byte, halfword, word, doubleword, and quadword operands, where each operand is contained in a GPR (or a pair of GPRs for quadword operands). Vector fixed-point instructions operate on vectors of nibble, byte, halfword, word, doubleword, and quadword operands, where each vector is contained in a VR. Scalar binary floating-point instructions operate on single-precision, double-precision, and quad-precision floating-point operands, where each operand is contained in an FPR or VSR. Scalar decimal floating-point instructions operate on short, long, and extended decimal floating-point operands, where each operand is contained in an FPR (or a pair of FPRs for quadword operands).

Vector floating-point instructions operate on vectors of single-precision and double-precision floating-point operands, where each vector is contained in a VR or VSR.

The Power ISA uses instructions that are four or eight bytes long and are word-aligned. It provides for byte, halfword, word, doubleword, and quadword operand loads and stores between storage and a set of 32 General Purpose Registers (GPRs). It provides for byte, halfword, word, doubleword, quadword, and octword operand loads and stores between storage and a set of 64 Vector-Scalar Registers (VSRs).

Signed integers are represented in two’s complement form.

There are no computational instructions that modify storage; instructions that reference storage may reformat the data (e.g., load halfword algebraic). To use a storage operand in a computation and then modify the same or another storage location, the contents of the storage operand must be loaded into a register, modified, and then stored back to the target location. Figure 1 is a logical representation of instruction processing. Figure 2 shows the registers that are defined in Book I. (A few additional registers that are available to application programs are defined in other Books, and are not shown in the figure.)
### Figure 2. Registers that are defined in Book I

#### 1.5 Computation modes

Processors provide two execution modes, 64-bit mode and 32-bit mode. In both of these modes, instructions that set a 64-bit register affect all 64 bits. The computational mode controls how the effective address is interpreted, how Condition Register bits and XER bits are set, how the Link Register is set by Branch instructions in which LK=1, and how the Count Register is tested by Branch Conditional instructions. Nearly all instructions are available in both modes (the only exceptions are a few instructions that are defined in Book III). In both modes, effective address computations use all 64 bits of the relevant registers (General Purpose Registers, Floating-Point Registers, etc.).
1.6 Instruction Formats

Instructions are encoded in either four or eight bytes and are word-aligned. When referring specifically to only one of these two types of instructions, the term “word instruction” is used to refer to instructions that are encoded in four bytes, and the term “prefixed instruction” is used to refer to instructions that are encoded in eight bytes using a prefix.

Bits 0:5 always specify the primary opcode (PO, below). Many instructions also have an extended opcode (XO, below). Some instructions also have a third, expanded opcode (EO, below). The remaining bits of the instruction contain one or more fields as shown below for the different instruction formats.

Since all instructions are word-aligned, whenever instruction addresses are presented to the processor (as in Branch instructions) the low-order two bits are ignored. Similarly, whenever the processor develops an instruction address the low-order two bits are zero.

Prefixed instructions consist of a four-byte prefix followed by a four-byte suffix. As such, the address of a prefixed instruction is the address of its prefix. For some prefixed instructions, the four-byte suffix is a defined word instruction, and the prefix modifies or extends the word instruction’s behavior. For other prefixed instructions, while the suffix may or may not correspond to (i.e., have the same 32-bit binary value as) a defined word instruction, the prefix causes the suffix to be decoded using a different opcode space from that used by defined word instructions.

Prefixed instructions do not cross 64-byte instruction address boundaries. When a prefixed instruction crosses a 64-byte boundary, the system alignment error handler is invoked.

Programming Note

Although instructions that set a 64-bit register affect all 64 bits in both 32-bit and 64-bit modes, operating systems often do not preserve the upper 32-bits of all registers across context switches done in 32-bit mode. For this reason, application programs operating in 32-bit mode should not assume that the upper 32 bits of the GPRs are preserved from instruction to instruction unless the operating system is known to preserve these bits.

Programming Note

The instruction address boundary error can only occur with prefixed instructions. Word instructions are word-aligned (four-byte), and thus cannot cross 64-byte boundaries.

The format diagrams given below show horizontally all valid combinations of instruction fields. See Section 1.6.3, “Instruction Prefix Formats” for definitions of instruction fields defined in the prefix.

Split Field Notation

In some cases an instruction field occupies more than one contiguous sequence of bits, or occupies one contiguous sequence of bits that are used in permuted order. Such a field is called a split field. In the format diagrams given below and in the individual instruction layouts, the name of a split field is shown in small letters, once for each of the contiguous sequences. In the RTL description of an instruction having a split field, and in certain other places where individual bits of a split field are identified, the name of the field in small letters represents the concatenation of the sequences from left to right. In all other places, the name of the field is capitalized and represents the concatenation of the sequences in some order, which need not be left to right, as described for each affected instruction.

Figure 27. Z23 instruction format

1.6.2 Word Instruction Fields

AA (30)

Absolute Address.

0 The immediate field represents an address relative to the current instruction address. For I-form branches the effective address of the branch target is the sum of the LI field sign-extended to 64 bits and the address of the branch instruction. For B-form branches the effective address of the branch target is the sum of the BD field sign-extended to 64 bits and the address of the branch instruction.

1 The immediate field represents an absolute address. For I-form branches the effective address of the branch target is the LI field sign-extended to 64 bits. For B-form branches the effective address of the branch target is the BD field sign-extended to 64 bits.

Formats: B, I

AX,A (29,11:15)

Fields that are concatenated to specify a VSR to be used as a source.

Formats: XX3, XX4

BA (11:15)

Field used to specify a bit in the CR to be used as a source.

Formats: XL

BB (16:20)

Field used to specify a bit in the CR to be used as a source.

Formats: XL

BC (21:25)

Field used to specify a bit in the CR to be used as a source.

Formats: A

BD (16:29)

Immediate field used to specify a 14-bit signed two’s complement branch displacement which is concatenated on the right with 0b00 and sign-extended to 64 bits.

Formats: B

BF (6:8)

Field used to specify one of the CR fields or one of the FPSCR fields to be used as a target.

Formats: D, X, XL, XX2, XX3, Z22

BFA (11:13)

Field used to specify one of the CR fields or one of the FPSCR fields to be used as a source.

Formats: X, XL

BH (19:20)

Field used to specify a hint in the Branch Conditional to Link Register and Branch Conditional to Count Register instructions. The encoding is described in Section 2.4, “Branch Instructions”.

Formats: XL

BHRBE (11:20)

Field used to identify the BHRB entry to be used as a source by the Move From Branch History Rolling Buffer instruction.

Formats: X

BI (11:15)

Field used to specify a bit in the CR to be tested by a Branch Conditional instruction.

Formats: B, XL

BO (6:10)

Field used to specify options for the Branch Conditional instructions. The encoding is described in Section 2.4, “Branch Instructions”.

Formats: B, XL, X, XL

BT (6:10)

Field used to specify a bit in the CR or in the FPSCR to be used as a target.

Formats: XL

BX,B (30,16:20)

Fields that are concatenated to specify a VSR to be used as a source.

Formats: XX2, XX3, XX4

CT (7:10)

Field used in X-form instructions to specify a cache target (see Section 4.3.2 of Book II).

Formats: X
CX,C (28,21:25)
Fields that are concatenated to specify a VSR to be used as a source.
Formats: XX4

D (16:31)
Immediate field used to specify a 16-bit signed two's complement integer which is sign-extended to 64 bits.
Formats: D

d0,d1,d2 (16:25,11:15,31)
Immediate fields that are concatenated to specify a 16-bit signed two's complement integer which is sign-extended to 64 bits.
Formats: DX

dc, dm, dx (25,29,11:15)
Immediate fields that are concatenated to specify Data Class Mask.
Formats: XX2

DCM (16:21)
Immediate field used to specify Data Class Mask.
Formats: Z22

DCMX (9:15)
Immediate field used to specify Data Class Mask.
Formats: X, XX2

DGM (16:21)
Immediate field used as the Data Group Mask.
Formats: Z22

DM (22:23)
Immediate field used by xxpermdi instruction as doubleword permute control.
Formats: XX3

DRM (18:20)
Immediate operand field used to specify new decimal floating-point rounding mode.
Formats: X

DQ (16:27)
Immediate field used to specify a 12-bit signed two's complement integer which is concatenated on the right with 0b0000 and sign-extended to 64 bits.
Formats: DQ

DS (16:29)
Immediate field used to specify a 14-bit signed two's complement integer which is concatenated on the right with 0b00 and sign-extended to 64 bits.
Formats: DS

EH (31)
Field used to specify a hint in the Load And Reserve instructions. The meaning is described in Section 4.6.2, “Load And Reserve and Store Conditional Instructions”, in Book II.
Formats: X

EO (11:12)
Expanded opcode field
Formats: X

EO (11:15)
Expanded opcode field
Formats: VX, X, XX2

EX (31)
Field used to specify Inexact form of round to quad-precision integer.
Formats: X

FC (16:20)
Field used to specify the function code in Load/Store Atomic instructions.
Formats: X

FLM (7:14)
Field mask used to identify the FPSCR fields that are to be updated by the mtfsf instruction.
Formats: XFL

FRA (11:15)
Field used to specify a FPR to be used as a source.
Formats: A, X, Z22, Z23

FR Ap (11:15)
Field used to specify an even/odd pair of FPRs to be concatenated and used as a source.
Formats: X, Z22, Z23

FRB (16:20)
Field used to specify an FPR to be used as a source.
Formats: A, X, XFL, Z23

FRBp (16:20)
Field used to specify an even/odd pair of FPRs to be concatenated and used as a source.
Formats: X, Z23

FRC (21:25)
Field used to specify an FPR to be used as a source.
Formats: A
FRS (6:10)
Field used to specify an FPR to be used as a source.
Formats: D, X

FRSp (6:10)
Field used to specify an even/odd pair of FPRs to be concatenated and used as a source.
Formats: DS, X

FRT (6:10)
Field used to specify an FPR to be used as a target.
Formats: A, D, X, Z22, Z23

FRTp (6:10)
Field used to specify an even/odd pair of FPRs to be concatenated and used as a target.
Formats: DS, X, Z22, Z23

FXM (12:19)
Field mask used to identify the CR fields that are to be written by the *mtcrf* and *mtocrf* instructions, or read by the *mfocrf* instruction.
Formats: XFX

IB (16:20)
Immediate field used to specify a 5-bit signed integer.
Formats: MDS

IH (8:10)
Field used to specify a hint in the *SLB Invalidate All* instruction. The meaning is described in Section 6.9.3.2, “SLB Management Instructions”, in Book III.
Formats: X

IMM8 (13:20)
Immediate field used to specify an 8-bit integer.
Formats: X

IS (6:10)
Immediate field used to specify a 5-bit signed integer.
Formats: MDS

L (6)
Field used to specify whether the *mtfsf* instruction updates the entire FPSCR.
Formats: XFL

L (10)
Field used to specify whether a fixed-point Compare instruction is to compare 64-bit numbers or 32-bit numbers.
Field used by the *Compare Range Byte* instruction to indicate whether to compare against 1 or 2 ranges of bytes.
Field used by the *Paste* instruction to indicate whether to zero the metadata.
Formats: D, X

L (15)
Field used by the *Move To Machine State Register* instruction (see Book III).
Field used by the *SLB Invalidate All Global* instruction to specify whether the invalidation is for a process or for a partition (see Section 6.9.3.2 of Book III).
Field used by the *SLB Move From Entry VSID* and *SLB Move From Entry ESID* instructions for implementation-specific purposes.
Formats: X

L (14:15)
Field used by the *Deliver A Random Number* instruction (see Section 3.3.9, “Fixed-Point Arithmetic Instructions”) to choose the random number format.
Formats: X

LEV (20:26)
Field used by the *System Call* instructions.
Formats: SC

LI (6:29)
Immediate field used to specify a 24-bit signed two’s complement integer which is concatenated on the right with 0b00 and sign-extended to 64 bits.
Formats: I

LK (31)
LINK bit.
0 Do not set the Link Register.
1 Set the Link Register. The address of the instruction following the *Branch* instruction is placed into the Link Register.
Formats: B, I, XL

MB (21:25)
Field used in M-form instructions to specify the first 1-bit of a 64-bit mask, as described in Section 3.3.14, “Fixed-Point Rotate and Shift Instructions” on page 107.
Formats: M
mb (21:26)
Field used in MD-form and MDS-form instructions to specify the first 1-bit of a 64-bit mask, as described in Section 3.3.14, “Fixed-Point Rotate and Shift Instructions” on page 107.
Formats: MD, MDS

me (21:26)
Field used in MD-form and MDS-form instructions to specify the last 1-bit of a 64-bit mask, as described in Section 3.3.14, “Fixed-Point Rotate and Shift Instructions” on page 107.
Formats: MD, MDS

ME (26:30)
Field used in M-form instructions to specify the last 1-bit of a 64-bit mask, as described in Section 3.3.14, “Fixed-Point Rotate and Shift Instructions” on page 107.
Formats: M

NB (16:20)
Field used to specify the number of bytes to move in an immediate Move Assist instruction.
Formats: X

OE (21)
Field used by XO-form instructions to enable setting OV and SO in the XER.
Formats: XO

PL (14:15)
Field used by the wait instruction to specify pause length.
Formats: X

PO (0:5)
Primary opcode.
Formats: all

PRS (14)
Field used to specify whether to invalidate process- or partition-scoped entries for tlbie[].
Formats: X

RC (21)
RECORD bit.
0 Do not alter the Condition Register.
1 Set Condition Register Field 0 or Field 1 as described in Section 2.3.1, “Condition Register” on page 34.
Formats: A, M, MD, MDS, VA, X, XO, XS

Rc (31)
RECORD bit.
0 Do not alter the Condition Register.
1 Set Condition Register Field 0 or Field 1 as described in Section 2.3.1, “Condition Register” on page 34.
Formats: A, M, MD, MDS, X, XFL, XO, XS, Z22, Z23

RIC (12:13)
Field used to specify what types of entries to invalidate for tlbie[].
Formats: X

RM (19:20)
Immediate operand field used to specify new binary floating-point rounding mode.
Formats: X

RMC (21:22)
Immediate field used for DFP rounding mode control.
Formats: Z23

</tbody>
</table>
TO (6:10)
Field used to specify the conditions on which to
trap. The encoding is described in
Section 3.3.10.1, “Character-Type Compare
Instructions” on page 94.
Formats: TX, X

TX,T (28,6:10)
Fields that are concatenated to specify a VSR to
be used as either a target.
Formats: DQ

TX,T (31,6:10)
Fields that are concatenated to specify a VSR to
be used as either a target or a source.
Formats: X, XX2, XX3, XX4

U (16:19)
Immediate field used as the data to be placed into
a field in the FPSCR.
Formats: X

UI (16:20)
Immediate field used to specify a 5-bit unsigned
integer.
Formats: TX

UI (16:31)
Immediate field used to specify a 16-bit unsigned
integer.
Formats: D

UIM (11:15)
Immediate field used to specify a 5-bit unsigned
integer.
Formats: VX, X

UIM (12:15)
Immediate field used to specify a 4-bit unsigned
integer.
Formats: VX, XX2

UIM (13:15)
Immediate field used to specify a 3-bit unsigned
integer.
Formats: VX

UIM (14:15)
Immediate field used to specify a 2-bit unsigned
integer.
Formats: VX, XX2

VRA (11:15)
Field used to specify a VR to be used as a source.
Formats: VA, VC, VX

VRB (16:20)
Field used to specify a VR to be used as a source.
Formats: VA, VC, VX

VRC (21:25)
Field used to specify a VR to be used as a source.
Formats: VA

VRS (6:10)
Field used to specify a VR to be used as a source.
Formats: DS, X

VRT (6:10)
Field used to specify a VR to be used as a target.
Formats: DS, VA, VC, VX, X

W (15)
Field used by the mtfsfi and mtfsf instructions to
specify the target word in the FPSCR.
Formats: X, XFL

WC (9:10)
Field used to specify the condition or conditions
that cause instruction execution to resume after
executing a wait instruction (see Section 4.6.4 of
Book II).
Formats: X

XBI (21:24)
Field used to specify a bit in the XER.

Extended opcode field.
Formats: XS, XX2

XO (21:30)
Extended opcode field.
Formats: X, XFL, XFX, XL
1.6.3 Instruction Prefix Formats

Prefixed instructions consist of a 4-byte prefix followed by a 4-byte suffix. The prefix formats are specified below. The suffix formats share the same formats as word instructions, as specified in Section 1.6.1 on page 12.

Bits 0:5 of all prefixes are assigned the primary opcode value \(0b000001\). \(0b000001\) is not available for use as a primary opcode for either word instructions or suffixes of prefixed instructions.

Prefix bits 6:7 are used to identify one of four prefix formats. When bit 6 is set to 0 (prefix types 00 and 01), the suffix is not a defined word instruction (i.e., requires the prefix to identify the alternate opcode space the suffix is assigned to as well as additional or extended operand and/or control fields); when bit 6 is set to 1 (prefix types 10 and 11), the prefix is modifying the behavior of a defined word instruction in the suffix.

1.6.3.1 Type 00 Prefix – Eight-Byte Load/Store Instructions

The Type 00 prefix format provides a one-bit subtype (ST) field to specify the subformat employed by the prefix. The subformats are defined as follows.

**ST=0: Eight-Byte Load/Store Form (8LS)**

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>ST</th>
<th>R</th>
<th>IE</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>8</td>
<td>9</td>
<td>11</td>
</tr>
</tbody>
</table>

ST=1: Reserved
1.6.3.2 Type 01 Prefix – Eight-Byte Register-to-Register Instructions

The Type 01 prefix format provides a four-bit subtype (ST) field to specify the subformat employed by the prefix. The subformats are defined as follows.

ST=0b0000: Eight-Byte Register-to-Register Form (8RR)

ST=0b0001-0b1000: Reserved

ST=0b1000-0b1001: Reserved

1.6.3.3 Type 10 - Modified Load/Store Instructions

The Type 10 prefix format provides a one-bit subtype (ST) field to specify the subformat employed by the prefix. The subformats are defined as follows.

ST=0: Modified Load/Store Form (MLS)

ST=1: Reserved

1.6.3.4 Type 11 - Modified Register-to-Register Instructions

The Type 11 prefix format provides a four-bit subtype (ST) field to specify the subformat employed by the prefix. The subformats are defined as follows.

ST=0b0000: Modified Register to Register Form (MRR)

ST=0b0001-0b1000: Reserved

ST=0b1000-0b1011: Reserved

1.6.4 Instruction Prefix Fields

IE (14:31)

18-bit immediate field that is concatenated with the D field in the suffix to extend the displacement value at the high-order end. This field is reserved when this prefix precedes instructions of other formats.

Alternate field names: d0, si0, imm18

Formats: 8LS, MLS

imm0 (16:31)

16-bit immediate field that is concatenated with the 16-bit immediate field in the suffix to create a 32-bit value.

Formats: 8RR

IMM (24:31)

8-bit immediate field used as control operand.

Formats: 8RR

PMSK (16:23)

Immediate field used to specify product mask for VSX Vector GER instructions.

Formats: MMIRR

PMSK (16:19)

Immediate field used to specify product mask for VSX Vector GER instructions.

Formats: MMIRR

PMSK (16:17)

Immediate field used to specify product mask for VSX Vector GER instructions.

Formats: MMIRR

- *pnop* (See Section 3.3.19, "Prefixed No-Operation Instruction" on page 130)
R (11)
Field used to specify whether the effective address of the storage operand is computed relative to the address of the instruction (CIA).

| 000 | Effective address is not computed relative to CIA |
| 001 | Effective address is computed relative to CIA |

Formats: 8LS, MLS

UIM (29:31)
3-bit immediate field used as control operand.

Formats: 8RR

XMSK (24:27)
Field used to specify ACC row mask for VSX Vector GER instructions.

Formats: MMIRR

YMSK (28:31)
Field used to specify ACC column mask for VSX Vector GER instructions.

Formats: MMIRR

1.7 Classes of Instructions

An instruction falls into exactly one of the following three classes:

- Defined
- Illegal
- Reserved

The class is determined by examining the opcode, and the extended opcode if any. If the opcode, or combination of opcode and extended opcode, is not that of a defined instruction or a reserved instruction, the instruction is illegal.

1.7.1 Defined Instruction Class

This class of instructions contains all the instructions defined in this document.

A defined instruction can have preferred and/or invalid forms, as described in Section 1.8.1, “Preferred Instruction Forms” and Section 1.8.2, “Invalid Instruction Forms”.

1.7.2 Illegal Instruction Class

This class of instructions contains the set of instructions described in Appendix B of Book Appendices. Illegal instructions are available for future extensions of the Power ISA; that is, some future version of the Power ISA may define any of these instructions to perform new functions.

Any attempt to execute an illegal instruction will cause the system illegal instruction error handler to be invoked and will have no other effect.

An instruction consisting entirely of binary 0s is guaranteed always to be an illegal instruction. This increases the probability that an attempt to execute data or uninitialized storage will result in the invocation of the system illegal instruction error handler.

1.7.3 Reserved Instruction Class

This class of instructions contains the set of instructions described in Appendix C of Book Appendices.

Reserved instructions are allocated to specific purposes that are outside the scope of the Power ISA.

Any attempt to execute a reserved instruction will:
- perform the actions described by the implementation if the instruction is implemented; or
- cause the system illegal instruction error handler to be invoked if the instruction is not implemented.

1.8 Forms of Defined Instructions

1.8.1 Preferred Instruction Forms

Some of the defined instructions have preferred forms. For such an instruction, the preferred form will execute in an efficient manner, but any other form may take significantly longer to execute than the preferred form.

Instructions having preferred forms are:
- the Condition Register Logical instructions
- the Load Quadword instruction
- the Move Assist instructions
- the Or Immediate instruction (preferred form of no-op)
- the Move To Condition Register Fields instruction

1.8.2 Invalid Instruction Forms

Some of the defined instructions can be coded in a form that is invalid. An instruction form is invalid if one or more fields of the instruction, excluding the opcode field(s), are coded incorrectly in a manner that can be deduced by examining only the instruction encoding.

In general, any attempt to execute an invalid form of an instruction will either cause the system illegal instruction error handler to be invoked or yield boundedly undefined results. Exceptions to this rule are stated in the instruction descriptions.
Some instruction forms are invalid because the instruction contains a reserved value in a defined field (see Section 1.3.3 on page 5); these invalid forms are not discussed further. All other invalid forms are identified in the instruction descriptions.

References to instructions elsewhere in this document assume the instruction form is not invalid, unless otherwise stated or obvious from context.

### Assembler Note

Assemblers should report uses of invalid instruction forms as errors.

#### 1.8.3 Reserved-no-op Instructions

Reserved-no-op instructions include the following extended opcodes under primary opcode 31: 530, 562, 594, 626, 658, 690, 722, and 754.

Reserved-no-op instructions are provided in the architecture to anticipate the eventual adoption of performance hint instructions to the architecture. For these instructions, which cause no visible change to architected state, employing a reserved-no-op opcode will allow software to use this new capability on new implementations that support it while remaining compatible with existing implementations that may not support the new function.

When a reserved-no-op instruction is executed, no operation is performed.

Reserved-no-op instructions are not assigned instruction names or mnemonics. There are no individual descriptions of reserved-no-op instructions in this document.

#### 1.9 Exceptions

There are two kinds of exception, those caused directly by the execution of an instruction and those caused by an asynchronous event. In either case, the exception may cause one of several components of the system software to be invoked.

The exceptions that can be caused directly by the execution of an instruction include the following:

- an attempt to execute an illegal instruction, or an attempt by an application program to execute a “privileged” instruction (see Book III) (system illegal instruction error handler or system privileged instruction error handler)
- the execution of a defined instruction using an invalid form (system illegal instruction error handler or system privileged instruction error handler)
- an attempt to execute an instruction that is not provided by the implementation (system illegal instruction error handler)
- an attempt to execute a prefixed instruction that crosses a 64-byte address boundary. (system alignment error handler)
- an attempt to access a storage location that is unavailable (system instruction storage error handler or system data storage error handler)
- an attempt to access storage with an effective address alignment that is invalid for the instruction (system alignment error handler)
- the execution of a System Call or System Call Vectorized instruction (system service program)
- the execution of a Trap instruction that traps (system trap handler)
- the execution of a floating-point instruction that causes a floating-point enabled exception to exist (system floating-point enabled exception error handler)

The exceptions that can be caused by an asynchronous event are described in Book III.

The invocation of the system error handler is precise, except that if one of the imprecise modes for invoking the system floating-point enabled exception error handler is in effect (see page 141), then the invocation of the system floating-point enabled exception error handler may also be imprecise. When the system error handler is invoked imprecisely, the excepting instruction does not appear to complete before the next instruction starts (because one of the effects of the excepting instruction, namely the invocation of the system error handler, has not yet occurred).

Additional information about exception handling can be found in Book III.

#### 1.10 Storage Addressing

A program references storage using the effective address computed by the processor when it executes a Storage Access or Branch instruction (or certain other instructions described in Book II and Book III), or when it fetches the next sequential instruction.

Bytes in storage are numbered consecutively starting with 0. Each number is the address of the corresponding byte.

The byte ordering (Big-Endian or Little-Endian) for a storage access is specified by the operating system. This byte ordering is also referred to as the Endian mode and it applies to both data accesses and instruction fetches. The Endian mode is specified by the LE mode bit (see Section 4.2.1 of Book III), which applies to all of storage.
1.10.1 Storage Operands

A storage operand may be a byte, a halfword, a word, a doubleword, a quadword, an octword, or, for the Load/Store Multiple, Move Assist, and Load/Store VSX Vector with Length [Left-justified] instructions, a sequence of bytes (Move Assist and Load/Store VSX Vector with Length [Left-justified]) or words (Load/Store Multiple). The address of a storage operand is the address of its first byte (i.e., of its lowest-numbered byte). An instruction for which the storage operand is a byte is said to cause a byte access, and similarly for halfword, word, doubleword, quadword, and octword.

The length of the storage operand is the number of bytes (of the storage operand) that the instruction would access in the absence of invocations of the system error handler. The length is generally implied by the name of the instruction (equivalently, by the opcode, and extended opcode if any). For example, the length of the storage operand of a Load Word and Zero, Load Floating-Point Single, and Load Vector Element Word instruction is four bytes (one word), the length of a Store Quadword, Store Floating-Point Double Pair, and Store VSX Vector Word*4 instruction is 16 bytes (one quadword), and the length of a Load VSX Vector Paired instruction is 32 bytes (one octword). The only exceptions are the Load/Store Multiple and Move Assist instructions, for which the length of the storage operand is implied by the identity of the specified source or target register (Load/Store Multiple), or by an immediate field in the instruction or the contents of a field in the XER (Move Assist), as well as by the name of the instruction. For example, the length of the storage operand of a Load Multiple Word instruction for which the specified target register is GPR 20 is 48 bytes ((32-20)x4), and the length of the storage operand of a Load String Word Immediate instruction for which the immediate field contains the number 20 is 20 bytes.

The storage operand of a Load or Store instruction other than a Load/Store Multiple or Move Assist instruction is said to be aligned if the address of the storage operand is an integral multiple of the storage operand length; otherwise it is said to be unaligned. See the following table. (The storage operand of a Load/Store Multiple or Move Assist instruction is neither said to be aligned nor said to be unaligned. Its alignment properties are described, when necessary, using terms such as “word-aligned”, which are defined below.)

<table>
<thead>
<tr>
<th>Operand</th>
<th>Length</th>
<th>Addr&lt;6:4&gt; if aligned</th>
</tr>
</thead>
<tbody>
<tr>
<td>Byte</td>
<td>8 bits</td>
<td>x x x x x x</td>
</tr>
<tr>
<td>Halfword</td>
<td>2 bytes</td>
<td>x x x x x 0</td>
</tr>
<tr>
<td>Word</td>
<td>4 bytes</td>
<td>x x 0 0 0 0</td>
</tr>
<tr>
<td>Doubleword</td>
<td>8 bytes</td>
<td>x 0 0 0 0 0 0</td>
</tr>
<tr>
<td>Quadword</td>
<td>16 bytes</td>
<td>0 0 0 0 0 0 0</td>
</tr>
<tr>
<td>Octword</td>
<td>32 bytes</td>
<td>0 0 0 0 0 0 0</td>
</tr>
</tbody>
</table>

Note: An “x” in an address bit position indicates that the bit can be 0 or 1 independent of the contents of other bits in the address.

The concept of alignment is also applied more generally, to any datum in storage.

A datum having length that is an integral power of 2 is said to be aligned if its address is an integral multiple of its length.

A datum of any length is said to be halfword-aligned (or aligned at a halfword boundary) if its address is an integral multiple of 2, word-aligned (or aligned at a word boundary) if its address is an integral multiple of 4, etc. (All data in storage is byte-aligned.)

The concept of alignment can also be applied to data in registers, with the “address” of the datum interpreted as the byte number of the datum in the register. E.g., a word element (4 bytes) in a Vector Register is said to be aligned if its byte number is an integral multiple of 4.

Programming Note

The technical literature sometimes uses the term “naturally aligned” to mean “aligned.” Versions of the architecture that precede Version 2.07 also used “naturally aligned” as defined above. The term was dropped from the architecture in Version 2.07 because it seemed to mean different things to different readers and is not needed.

Some instructions require their storage operands to have certain alignments. In addition, alignment may affect performance. In general, the best performance is obtained when storage operands are aligned.

When a storage operand of length N bytes starting at effective address EA is copied between storage and a register that is R bytes long (i.e., the register contains bytes numbered from 0, most significant, through R-1, least significant), the bytes of the operand are placed into the register or into storage in a manner that depends on the byte ordering for the storage access as shown in Figure 28, unless otherwise specified in the instruction description.
Chapter 1. Introduction

**Figure 28. Storage operands and byte ordering**

Figure 29 shows an example of a C language structure `s` containing an assortment of scalars and one character string. The value assumed to be in each structure element is shown in hex in the C comments; these values are used below to show how the bytes making up each structure element are mapped into storage. It is assumed that structure `s` is compiled for 32-bit mode or for a 32-bit implementation. (This affects the length of the pointer to `c`.)

C structure mapping rules permit the use of padding (skipped bytes) in order to align the scalars on desirable boundaries. Figures 30 and 31 show each scalar as aligned. This alignment introduces padding of four bytes between `a` and `b`, one byte between `d` and `e`, and two bytes between `e` and `f`. The same amount of padding is present for both Big-Endian and Little-Endian mappings.

The Big-Endian mapping of structure `s` is shown in Figure 30. Addresses are shown in hex at the left of each doubleword, and in small figures below each byte. The contents of each byte, as indicated in the C example in Figure 29, are shown in hex (as characters for the elements of the string).

The Little-Endian mapping of structure `s` is shown in Figure 31. Doublewords are shown laid out from right to left, which is the common way of showing storage maps for processors that implement only Little-Endian byte ordering.

</tbody>
</table>

**Notes:**
1. In this table, subscripts refer to bytes in a register.
2. This table does not apply to the `lvebx`, `lvehx`, `lvex`, `stvebx`, `stvehx`, and `stvex` instructions.
1.10.2 Instruction Fetches

Instructions are encoded in either four or eight bytes and are word-aligned. For purposes of byte ordering, prefixed instructions are treated as if they are two independent four-byte instructions, with the prefix preceding the suffix in storage regardless of the Endian mode.

When an instruction starting at effective address EA is fetched from storage, the relative order of the bytes within each word of the instruction image depends on the byte ordering for the storage access as shown in Figure 32.

The Big-Endian mapping of program p is shown in Figure 34 (assuming the program starts at address 0).

The Little-Endian mapping of program p is shown in Figure 35.

Figure 32. Instructions and byte ordering

Figure 33 shows an example of a small assembly language program p. In the program, prefixed instruction 1 is doubleword-aligned and prefixed instruction 2 is word-aligned.

Figure 33. Assembly language program ‘p’
Programming Note

The terms Big-Endian and Little-Endian come from Part I, Chapter 4, of Jonathan Swift’s Gulliver’s Travels. Here is the complete passage, from the edition printed in 1734 by George Faulkner in Dublin.

... our Histories of six Thousand Moons make no Mention of any other Regions, than the two great Empires of Lilliput and Blefuscu. Which two mighty Powers have, as I was going to tell you, been engaged in a most obstinate War for six and thirty Moons past. It began upon the following Occasion. It is allowed on all Hands, that the primitive Way of breaking Eggs before we eat them, was upon the larger End: But his present Majesty’s Grand-father, while he was a Boy, going to eat an Egg, and breaking it according to the ancient Practice, happened to cut one of his Fingers. Whereupon the Emperor his Father, published an Edict, commanding all his Subjects, upon great Penalties, to break the smaller End of their Eggs. The People so highly resented this Law, that our Histories tell us, there have been six Rebellions raised on that Account; wherein one Emperor lost his Life, and another his Crown. These civil Commotions were constantly fomented by the Monarchs of Lilliput and Blefuscu; and when they were quelled, the Exiles always fled for Refuge to that Empire. It is computed that eleven Thousand Persons have, at several Times, suffered Death, rather than submit to break their Eggs at the smaller End. Many hundred large Volumes have been published upon this Controversy: But the Books of the Big-Endians have been long forbidden, and the whole Party rendered incapable by Law of holding Employments. During the Course of these Troubles, the Emperors of Blefuscu did frequently expostulate by their Ambassadors, accusing us of making a Schism in Religion, by offending against a fundamental Doctrine of our great Prophet Lustrog, in the fifty-fourth Chapter of the Brundrecal, (which is their Alcoran.) This, however, is thought to be a mere Strain upon the text: For the Words are these: That all true Believers shall break their Eggs at the convenient End: and which is the convenient End, seems, in my humble Opinion, to be left to every Man’s Conscience, or at least in the Power of the chief Magistrate to determine. Now the Big-Endian Exiles have found so much Credit in the Emperor of Blefuscu’s Court; and so much private Assistance and Encouragement from their Party here at home, that a bloody War has been carried on between the two Empires for six and thirty Moons with various Success; during which Time we have lost Forty Capital Ships, and a much greater Number of smaller Vessels, together with thirty thousand of our best Sea-men and Soldiers; and the Damage received by the Enemy is reckoned to be somewhat greater than ours. However, they have now equipped a numerous Fleet, and are just preparing to make a Descent upon us: and his Imperial Majesty, placing great Confidence in your Valour and Strength, hath commanded me to lay this Account of his Affairs before you.

1.10.3 Effective Address Calculation

An effective address is computed by the processor when executing a Storage Access or Branch instruction (or certain other instructions described in Book II and Book III) when fetching the next sequential instruction, or when invoking a system error handler. The following provides an overview of this process. More detail is provided in the individual instruction descriptions.

Effective address calculations, for both data and instruction accesses, use 64-bit two’s complement addition. All 64 bits of each address component participate in the calculation regardless of mode (32-bit or 64-bit). In this computation one operand is an address (which is by definition an unsigned number) and the second is a signed offset. Carries out of the most significant bit are ignored.

In 64-bit mode, the entire 64-bit result comprises the 64-bit effective address. The effective address arithmetic wraps around from the maximum address, \(2^{64} - 1\), to address 0, except that if the current instruction is a word instruction at effective address \(2^{64} - 4\) or a prefixed instruction at effective address \(2^{64} - 8\), the effective address of the next sequential instruction is undefined, and if the current instruction is a prefixed instruction at effective address \(2^{64} - 4\), the effective address of the suffix is undefined.

In 32-bit mode, the low-order 32 bits of the 64-bit result, preceded by 32 0 bits, comprise the 64-bit effective address for the purpose of addressing storage, except that if the current instruction is a word instruction at effective address \(2^{32} - 4\) or a prefixed instruction at effective address \(2^{32} - 8\), the 64-bit effective address of the next sequential instruction is undefined, and if the current instruction is a prefixed instruction at effective address \(2^{32} - 4\), the effective address of the suffix is undefined. Thus, as used to address storage, the effective address arithmetic appears to wrap around from
the maximum address $^{232-1}$, to address 0, except when the resulting 64-bit effective address is undefined as just described. When an effective address is placed into a register by an instruction or event, the value placed into the register is as follows.

- **Register RA** when set by Load with Update and Store with Update instructions: the entire 64-bit result.

- **All other cases** (e.g., the Link Register when set by Branch instructions having LK=1, Special Purpose Registers when set to an effective address by invocation of a system error handler): the low-order 32 bits of the 64-bit result preceded by 32 0 bits, except that if the intended effective address is that of the NIA of either a word instruction at effective address $^{232-4}$, or a prefixed instruction at effective address $^{232-8}$, the value placed into the register is undefined.

RA is a field in the instruction which specifies an address component in the computation of an effective address. A zero in the RA field indicates the absence of the corresponding address component. A value of zero is substituted for the absent component of the effective address computation. This substitution is shown in the instruction descriptions as (RA=0).

Effective addresses are computed as follows. In the descriptions below, it should be understood that “the contents of a GPR” refers to the entire 64-bit contents, independent of mode, but that in 32-bit mode only bits 32:63 of the 64-bit result of the computation are used to address storage.

- **With X-form instructions**, in computing the effective address of a data element, the contents of the GPR designated by RB (or the value zero for ldat, lswi, lwat, lxvl, lxvll, stdat, stswi, stwat, stxvl, and stxvll) are added to the contents of the GPR designated by RA or to zero if RA=0 or RA is not used in forming the EA.

- **With X-form instructions** that are preceded by an MLS-form or MMLS-form prefix with the R bit set to 1 (see xref to Section 1.6.2), in computing the effective address of the data element, the contents of the GPR designated by RB are added to the CIA and RA is not used in forming the EA.

- **With DQ-form instructions**, the 16-bit D field is sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0.

- **With prefixed instructions having a D-form suffix** and an MLS-form or 8LS-form prefix, the 16-bit D field is concatenated on the left with the 18-bit IE field in the prefix, and the concatenation is sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0. If the R bit in the prefix is set to 0, or is added to the CIA if the R bit in the prefix is set to 1.

- **With prefixed instructions** having a D-form suffix and an MMLS-form or 8MLS-form prefix, the 16-bit D field is concatenated on the left with the 12-bit IE field in the prefix, and the concatenation is sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0 if the R bit in the prefix is set to 0, or is added to the CIA if the R bit in the prefix is set to 1.

- **With DS-form instructions**, the 14-bit DS field is concatenated on the right with 0b00 and sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0.

- **With prefixed instructions** having a DS-form suffix and an MLS-form or 8LS-form prefix, the 14-bit D field is concatenated on the right with 0b00 and is concatenated on the left with the 12-bit IE field in the prefix, and the concatenation is sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0 if the R bit in the prefix is set to 0, or is added to the CIA if the R bit in the prefix is set to 1.

- **With prefixed instructions** having a DS-form suffix and an MMLS-form or 8MLS-form prefix, the 14-bit D field is concatenated on the right with 0b00 and is concatenated on the left with the 12-bit IE field in the prefix, and the concatenation is sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0 if the R bit in the prefix is set to 0, or is added to the CIA if the R bit in the prefix is set to 1.

- **With prefixed instructions** having a DS-form suffix and an MLS-form or 8LS-form prefix, the 12-bit DQ field is concatenated on the right with 0b0000 and sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0.

- **With prefixed instructions** having a DQ-form suffix and an MLS-form or 8LS-form prefix, the 12-bit DQ field is concatenated on the right with 0b0000 and is concatenated on the left with the 18-bit IE field in the prefix, and the concatenation is sign-extended to form a 64-bit address component. In computing
the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0 if the R bit in the prefix is set to 0, or is added to the CIA if the R bit in the prefix is set to 1.

With prefixed instructions having a DQ-form suffix and an MMLS-form or 8MLS-form prefix, the 12-bit DQ field is concatenated on the right with 0b0000 and is concatenated on the left with the 12-bit IE field in the prefix, and the concatenation is sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0 if the R bit in the prefix is set to 0, or is added to the CIA if the R bit in the prefix is set to 1.

- With I-form Branch instructions, the 24-bit LI field is concatenated on the right with 0b00 and sign-extended to form a 64-bit address component. If AA=0, this address component is added to the address of the Branch instruction to form the effective address of the target instruction. If AA=1, this address component is the effective address of the target instruction.

- With B-form Branch instructions, the 14-bit BD field is concatenated on the right with 0b00 and sign-extended to form a 64-bit address component. If AA=0, this address component is added to the address of the Branch instruction to form the effective address of the target instruction. If AA=1, this address component is the effective address of the target instruction.

- With XL-form Branch instructions, bits 0:61 of the Link Register or the Count Register are concatenated on the right with 0b00 to form the effective address of the target instruction.

- With sequential instruction fetching, if the current instruction is a word instruction, the value 4 is added to the address of the current instruction to form the effective address of the next instruction, and if the current instruction is a prefixed instruction, the value 8 is added to the address of the current instruction to form the effective address of the next instruction, except that if the current instruction is at the maximum instruction effective address for the mode (for a word instruction, $2^{64} - 4$ in 64-bit mode and $2^{32} - 4$ in 32-bit mode; for a prefixed instruction, $2^{64} - 8$ in 64-bit mode and $2^{32} - 8$ in 32-bit mode) the effective address of the next sequential instruction is undefined.

If the size of the operand of a Storage Access instruction is more than one byte, the effective address for each byte after the first is computed by adding 1 to the effective address of the preceding byte.
Chapter 2. Branch Facility

2.1 Branch Facility Overview

This chapter describes the registers and instructions that make up the Branch Facility.

2.2 Instruction Execution Order

In general, instructions appear to execute sequentially, in the order in which they appear in storage. The exceptions to this rule are listed below.

- **Branch** instructions for which the branch is taken cause execution to continue at the target address specified by the Branch instruction.

- **Trap** instructions for which the trap conditions are satisfied, and **System Call** and **System Call Vectored** instructions, cause the appropriate system handler to be invoked.

- Event-based exceptions can cause the event-based branch handler to be invoked, as described in Chapter 6 of Book II.

- Exceptions can cause the system error handler to be invoked, as described in Section 1.9, “Exceptions” on page 25.

- Returning from a system service program, system trap handler, or system error handler causes execution to continue at a specified address.

The model of program execution in which the processor appears to execute one instruction at a time, completing each instruction before beginning to execute the next instruction is called the “sequential execution model”. In general, the processor obeys the sequential execution model. For the instructions and facilities defined in this Book, the only exceptions to this rule are the following.

- A floating-point exception occurs when the processor is running in one of the Imprecise floating-point exception modes (see Section 4.4). The instruction that causes the exception need not complete before the next instruction begins execution, with respect to setting exception bits and (if the exception is enabled) invoking the system error handler.

- A **Store** instruction modifies one or more bytes in an area of storage that contains instructions that will subsequently be executed. Before an instruction in that area of storage is executed, software synchronization is required to ensure that the instructions executed are consistent with the results produced by the Store instruction.

---

**Programming Note**

This software synchronization will generally be provided by system library programs (see Section 1.8 of Book II). Application programs should call the appropriate system library program before attempting to execute modified instructions.
2.3 Branch Facility Registers

2.3.1 Condition Register

The Condition Register (CR) is a 32-bit register which reflects the result of certain operations, and provides a mechanism for testing (and branching).

![Condition Register Diagram]

The bits in the Condition Register are grouped into eight 4-bit fields, named CR Field 0 (CR0), ..., CR Field 7 (CR7), which are set in one of the following ways.

- Specified fields of the CR can be set by a move to the CR from a GPR (mtcrf, mtocrf).
- A specified field of the CR can be set by a move to the CR from another CR field (mcrf), from OV, CA, OV32, and CA32 (mcrxr), or from the FPSCR (mcrfs).
- CR Field 0 can be set as the implicit result of a fixed-point instruction.
- CR Field 1 can be set as the implicit result of a floating-point instruction.
- CR Field 1 can be set as the implicit result of a decimal floating-point instruction.
- CR Field 6 can be set as the implicit result of a vector instruction.
- A specified CR field can be set as the result of a Compare instruction.

Instructions are provided to perform logical operations on individual CR bits and to test individual CR bits.

For all fixed-point instructions in which Rc=1, and for addic, andi, and andis, the first three bits of CR Field 0 (bits 32:34 of the Condition Register) are set by signed comparison of the result to zero, and the fourth bit of CR Field 0 (bit 35 of the Condition Register) is copied from the SO field of the XER. "Result" here refers to the entire 64-bit value placed into the target register in 64-bit mode, and to bits 32:63 of the 64-bit value placed into the target register in 32-bit mode.

```plaintext
if (64-bit mode)
    then M ← 0
else M ← 32
if (target_register)M,63 < 0 then c ← 0b100
else if (target_register)M,63 > 0 then c ← 0b010
else c ← 0b001
CR0 ← c || XERSO
```

If any portion of the result is undefined, then the value placed into the first three bits of CR Field 0 is undefined.

The bits of CR Field 0 are interpreted as follows.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Negative (LT)</td>
</tr>
<tr>
<td>1</td>
<td>Positive (GT)</td>
</tr>
<tr>
<td>2</td>
<td>Zero (EQ)</td>
</tr>
<tr>
<td>3</td>
<td>Summary Overflow (SO)</td>
</tr>
</tbody>
</table>

This is a copy of the contents of XERSO at the completion of the instruction.

The `paste` instruction (see Section 4.4, “Copy-Paste Facility”, in Book II) and the stbcx, sthcx, stwcx, stdcx, and stqcx instructions (see Section 4.6.2, “Load And Reserve and Store Conditional Instructions”, in Book II) also set CR Field 0.

For all floating-point instructions in which Rc=1, CR Field 1 (bits 36:39 of the Condition Register) is set to the Floating-Point exception status, copied from bits 32:35 of the Floating-Point Status and Control Register. This occurs regardless of whether any exceptions are enabled, and regardless of whether the writing of the result is suppressed (see Section 4.4, “Floating-Point Exceptions” on page 140). These bits are interpreted as follows.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>32</td>
<td>Floating-Point Exception Summary (FX)</td>
</tr>
<tr>
<td></td>
<td>This is a copy of the contents of FPSCRFX at</td>

</tr>
<tr>
<td></td>
<td>the completion of the instruction.</td>
</tr>
</tbody>
</table>

For Compare instructions, a specified CR field is set to reflect the result of the comparison. The bits of the specified CR field are interpreted as follows. A complete description of how the bits are set is given in the instruction descriptions in Section 3.3.10, “Fixed-Point Compare Instructions” on page 92, and Section 4.6.8, “Floating-Point Compare Instructions” on page 179.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Less Than, Floating-Point Less Than (LT, FL)</td>
</tr>
</tbody>
</table>
For fixed-point Compare instructions, (RA) < SI or (RB) (signed comparison) or (RA) < UI or (RB) (unsigned comparison). For floating-point Compare instructions, (FRA) < (FRB).

1 **Greater Than, Floating-Point Greater Than** (GT, FG)
   For fixed-point Compare instructions, (RA) > SI or (RB) (signed comparison) or (RA) > UI or (RB) (unsigned comparison). For floating-point Compare instructions, (FRA) > (FRB).

2 **Equal, Floating-Point Equal** (EQ, FE)
   For fixed-point Compare instructions, (RA) = SI, UI, or (RB). For floating-point Compare instructions, (FRA) = (FRB).

3 **Summary Overflow, Floating-Point Unordered** (SO, FU)
   For fixed-point Compare instructions, this is a copy of the contents of XERSO at the completion of the instruction. For floating-point Compare instructions, one or both of (FRA) and (FRB) is a NaN.

The Vector Integer Compare instructions (see Section 6.9.3, ”Vector Integer Compare Instructions“) compare two Vector Registers element by element, interpreting the elements as unsigned or signed integers depending on the instruction, and set the corresponding element of the target Vector Register to all 1s if the relation being tested is true and 0s if the relation being tested is false.

If Rc=1, CR Field 6 is set to reflect the result of the comparison, as follows

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The relation is true for all element pairs (i.e., VRT is set to all 1s).</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>The relation is false for all element pairs (i.e., VRT is set to all 0s).</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
</tr>
</tbody>
</table>

The Vector Floating-Point Compare instructions compare two Vector Registers word element by word element, interpreting the elements as single-precision floating-point numbers. With the exception of the Vector Compare Bounds Floating-Point instruction, they set the target Vector Register, and CR Field 6 if Rc=1, in the same manner as do the Vector Integer Compare instructions.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The relation is true for all element pairs (i.e., VRT is set to all 1s).</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

2 The relation is false for all element pairs (i.e., VRT is set to all 0s).
3 0

The Vector Compare Bounds Floating-Point instruction on page 429 sets CR Field 6 if Rc=1, to indicate whether the elements in VRA are within the bounds specified by the corresponding element in VRB, as explained in the instruction description. A single-precision floating-point value x is said to be ”within the bounds” specified by a single-precision floating-point value y if \(-y \leq x \leq y\).

<table>
<thead>
<tr>

<td>Set to indicate whether all four elements in VRA are within the bounds specified by the corresponding element in VRB, otherwise set to 0.</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
</tr>
</tbody>
</table>

### 2.3.2 Link Register

The Link Register (LR) is a 64-bit register. It can be used to provide the branch target address for the Branch Conditional to Link Register instruction, and it holds the return address after Branch instructions for which LK=1 and after System Call Vectored instructions.

<table>
<thead>
<tr>
<th>LR</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>63</td>
</tr>
</tbody>
</table>

Figure 37. Link Register

### 2.3.3 Count Register

The Count Register (CTR) is a 64-bit register. It can be used to hold a loop count that can be decremented during execution of Branch instructions that contain an appropriately coded BO field. If the value in the Count Register is 0 before being decremented, it is -1 afterward. The Count Register can also be used to provide the branch target address for the Branch Conditional to Count Register instruction. The Count Register is modified by the System Call Vectored instruction.

<table>
<thead>
<tr>
<th>CTR</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>63</td>
</tr>
</tbody>
</table>

Figure 38. Count Register

### 2.3.4 Target Address Register

The Target Address Register (TAR) is a 64-bit register. It can be used to provide bits 0:61 of the branch target
address for the Branch Conditional to Branch Target Address Register instruction. Bits 62:63 are ignored by the hardware but can be set and reset by software.

<table>
<thead>
<tr>
<th>Effective Address</th>
<th>62</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Figure 39. Target Address Register

**Programming Note**
The TAR is reserved for system software.
2.4 Branch Instructions

The sequence of instruction execution can be changed by the Branch instructions. Because all instructions are on word boundaries, bits 62 and 63 of the generated branch target address are ignored by the processor in performing the branch.

The Branch instructions compute the effective address (EA) of the target in one of the following five ways, as described in Section 1.10.3, “Effective Address Calculation” on page 29.

1. Adding a displacement to the address of the Branch instruction (Branch or Branch Conditional with AA=0).
2. Specifying an absolute address (Branch or Branch Conditional with AA=1).
3. Using the address contained in the Link Register (Branch Conditional to Link Register).
4. Using the address contained in the Count Register (Branch Conditional to Count Register).
5. Using the address contained in the Target Address Register (Branch Conditional to Target Address Register).

In all five cases, in 32-bit mode the final step in the address computation is setting the high-order 32 bits of the target address to 0.

For the first two methods, the target addresses can be computed sufficiently ahead of the Branch instruction that instructions can be prefetched along the target path. For the third through fifth methods, prefetching instructions along the target path is also possible provided the Link Register or the Count Register is loaded sufficiently ahead of the Branch instruction.

Branching can be conditional or unconditional, and the return address can optionally be provided. If the return address is to be provided (LK=1), the effective address of the instruction following the Branch instruction is placed into the Link Register after the branch target address has been computed; this is done regardless of whether the branch is taken.

For Branch Conditional instructions, the BO field specifies the conditions under which the branch is taken, as shown in Figure 40. In the figure, M=0 in 64-bit mode and M=32 in 32-bit mode.

<table>
<thead>
<tr>
<th>BO</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>000z</td>
<td>Decrement the CTR, then branch if the decremented ( CTR_{M:63} \neq 0 ) and ( CR_{BI}=0 )</td>
</tr>
<tr>
<td>001z</td>
<td>Decrement the CTR, then branch if the decremented ( CTR_{M:63} = 0 ) and ( CR_{BI}=0 )</td>
</tr>
<tr>
<td>01at</td>
<td>Branch if ( CR_{BI}=0 )</td>
</tr>
<tr>
<td>0100z</td>
<td>Decrement the CTR, then branch if the decremented ( CTR_{M:63} \neq 0 ) and ( CR_{BI}=1 )</td>
</tr>
<tr>
<td>0101z</td>
<td>Decrement the CTR, then branch if the decremented ( CTR_{M:63} = 0 ) and ( CR_{BI}=1 )</td>
</tr>
<tr>
<td>011at</td>
<td>Branch if ( CR_{BI}=1 )</td>
</tr>
<tr>
<td>1a00t</td>
<td>Decrement the CTR, then branch if the decremented ( CTR_{M:63} \neq 0 )</td>
</tr>
<tr>
<td>1a01t</td>
<td>Decrement the CTR, then branch if the decremented ( CTR_{M:63} = 0 )</td>
</tr>
<tr>
<td>1z1zz</td>
<td>Branch always</td>
</tr>
</tbody>
</table>

Notes:
1. “z” denotes a bit that is ignored.
2. The “a” and “t” bits are used as described below.

Figure 40. BO field encodings

The “a” and “t” bits of the BO field can be used by software to provide a hint about whether the branch is likely to be taken or is likely not to be taken, as shown in Figure 41.

<table>
<thead>
<tr>
<th>at</th>
<th>Hint</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No hint is given</td>
</tr>
<tr>
<td>01</td>
<td>Reserved</td>
</tr>
<tr>
<td>10</td>
<td>The branch is very likely not to be taken</td>
</tr>
<tr>
<td>11</td>
<td>The branch is very likely to be taken</td>
</tr>
</tbody>
</table>

Figure 41. “at” bit encodings

Programming Note

Many implementations have dynamic mechanisms for predicting whether a branch will be taken. Because the dynamic prediction is likely to be very accurate, and is likely to be overridden by any hint provided by the “at” bits, the “at” bits should be set to 0b00 unless the static prediction implied by at=0b10 or at=0b11 is highly likely to be correct.

For Branch Conditional to Link Register, Branch Conditional to Count Register, and Branch Conditional to Target Address Register instructions, the BH field provides...
a hint about the use of the instruction, as shown in Figure 42.

<table>
<thead>
<tr>

</table>

**Figure 42. BH field encodings**

**Programming Note**

The hint provided by the BH field is independent of the hint provided by the “at” bits (e.g., the BH field provides no indication of whether the branch is likely to be taken).

**Extended mnemonics for branches**

Many extended mnemonics are provided so that \textit{Branch Conditional} instructions can be coded with portions of the BO and BI fields as part of the mnemonic rather than as part of a numeric operand. Some of these are shown as examples with the Branch instructions. See Appendix C for additional extended mnemonics.

**Programming Note**

The hints provided by the “at” bits and by the BH field do not affect the results of executing the instruction.

The “z” bits should be set to 0, because they may be assigned a meaning in some future version of the architecture.
Many implementations have dynamic mechanisms for predicting the target addresses of \texttt{bclr[l]} and \texttt{bcctr[l]} instructions. These mechanisms may cache return addresses (i.e., Link Register values set by \textit{Branch} instructions for which \textit{LK}=1 and for which the branch was taken, other than the special form shown in the first example below) and recently used branch target addresses. To obtain the best performance across the widest range of implementations, the programmer should obey the following rules.

- Use \textit{Branch} instructions for which \textit{LK}=1 only as subroutine calls (including function calls, etc.), or in the special form shown in the first example below.
- Pair each subroutine call (i.e., each \textit{Branch} instruction for which \textit{LK}=1 and the branch is taken, other than the special form shown in the first example below) with a \texttt{bclr} instruction that returns from the subroutine and has BH=0b00.
- Do not use \texttt{bclrl} as a subroutine call. (Some implementations access the return address cache at most once per instruction; such implementations are likely to treat \texttt{bclrl} as a subroutine return, and not as a subroutine call.)
- For \texttt{bclr[l]} and \texttt{bcctr[l]}, use the appropriate value in the BH field.

The following are examples of programming conventions that obey these rules. In the examples, BH is assumed to contain 0b00 unless otherwise stated. In addition, the “at” bits are assumed to be coded appropriately.

Let A, B, and Glue be specific programs.

- Obtaining the address of the next instruction:
  Use the following form of \textit{Branch and Link}.
  \begin{verbatim}
  bcl 20,31,$+4
  \end{verbatim}

- Loop counts:
  Keep them in the Count Register, and use a \texttt{bc} instruction (LK=0) to decrement the count and to branch back to the beginning of the loop if the decremented count is nonzero.

- Computed goto’s, case statements, etc.:
  Use the Count Register to hold the address to branch to, and use a \texttt{bcctr} instruction (LK=0, and BH=0b11 if appropriate) to branch to the selected address.

- Direct subroutine linkage:
  Here A calls B and B returns to A. The two branches should be as follows.
  - A calls B: use a \texttt{bl} or \texttt{bcl} instruction (LK=1).
  - B returns to A: use a \texttt{bclr} instruction (LK=0) (the return address is in, or can be restored to, the Link Register).

- Indirect subroutine linkage:
  Here A calls Glue, Glue calls B, and B returns to A rather than to Glue. (Such a calling sequence is common in linkage code used when the subroutine that the programmer wants to call, here B, is in a different module from the caller; the Binder inserts “glue” code to mediate the branch.) The three branches should be as follows.
  - A calls Glue: use a \texttt{bl} or \texttt{bcl} instruction (LK=1).
  - Glue calls B: place the address of B into the Count Register, and use a \texttt{bcctr} instruction (LK=0).
  - B returns to A: use a \texttt{bclr} instruction (LK=0) (the return address is in, or can be restored to, the Link Register).

- Function call:
  Here A calls a function, the identity of which may vary from one instance of the call to another, instead of calling a specific program B. This case should be handled using the conventions of the preceding two bullets, depending on whether the call is direct or indirect, with the following differences.
  - If the call is direct, place the address of the function into the Count Register, and use a \texttt{bcctr} instruction (LK=1) instead of a \texttt{bl} or \texttt{bcl} instruction.
  - For the \texttt{bcctr[l]} instruction that branches to the function, use BH=0b11 if appropriate.
The bits corresponding to the current “a” and “t” bits, and to the current “z” bits except in the “branch always” BO encoding, had different meanings in versions of the architecture that precede Version 2.00.

- The bit corresponding to the “t” bit was called the “y” bit. The “y” bit indicated whether to use the architected default prediction (y=0) or to use the complement of the default prediction (y=1). The default prediction was defined as follows.
  - If the instruction is $bc[l]\{a\}$ with a negative value in the displacement field, the branch is taken. (This is the only case in which the prediction corresponding to the “y” bit differs from the prediction corresponding to the “t” bit.)
  - In all other cases ($bc[l]\{a\}$ with a nonnegative value in the displacement field, $bclr[l]$, or $bcctr[l]$), the branch is not taken.

- The BO encodings that test both the Count Register and the Condition Register had a “y” bit in place of the current “z” bit. The meaning of the “y” bit was as described in the preceding item.

- The “a” bit was a “z” bit.

Because these bits have always been defined either to be ignored or to be treated as hints, a given program will produce the same result on any implementation regardless of the values of the bits. Also, because even the “y” bit is ignored, in practice, by most processors that comply with versions of the architecture that precede Version 2.00, the performance of a given program on those processors will not be affected by the values of the bits.
**Branch I-form**

<table>
<thead>
<tr>

<td></td>
</tr>
<tr>
<td>bla</td>
<td>BO, BI, target_addr</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**target_addr** specifies the branch target address.

If AA=0 then the branch target address is the sum of LI || 0b00 sign-extended and the address of this instruction, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If AA=1 then the branch target address is the value LI || 0b00 sign-extended, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the Branch instruction is placed into the Link Register.

**Special Registers Altered:**

- LR (if LK=1)

**Extended Mnemonics:**

Examples of extended mnemonics for Branch Conditional:

- **blt** target
- **bne** cr2, target
- **bdz** target

**Equivalent to:**

- **bc** 12,0,target
- **bc** 4,10,target
- **bc** 16,0,target

**18 LI**

if AA then NIA ←₁₀₂₃ EXTS(LI || 0b00)
else NIA ←₁₀₂₃ CIA + EXTS(LI || 0b00)
if LK then LR ←₁₀₂₃ CIA + 4

**16 BO BI BD**

if (64-bit mode) then M ← 0
else M ← 32
if ¬BO₂ then CTR ← CTR - 1
cond_ok ← BO₂ | (CTR₂₆:₂₃ ≠ 0) ⊕ BO₂
if cond_ok then
    if AA then NIA ←₁₀₂₃ EXTS(BD || 0b00)
else NIA ←₁₀₂₃ CIA + EXTS(BD || 0b00)
if LK then LR ←₁₀₂₃ CIA + 4

BI+32 specifies the Condition Register bit to be tested. The BO field is used to resolve the branch as described in Figure 40. **target_addr** specifies the branch target address.

If AA=0 then the branch target address is the sum of BD || 0b00 sign-extended and the address of this instruction, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If AA=1 then the branch target address is the value BD || 0b00 sign-extended, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the Branch instruction is placed into the Link Register.

**Special Registers Altered:**

- CTR (if BO₂=0)
- LR (if LK=1)
**Branch Conditional to Link Register**

**XL-form**

<table>
<thead>
<tr>
<th>BO</th>
<th>BI</th>
<th>BH</th>
<th>LK</th>
</tr>
</thead>
<tbody>
<tr>
<td>19</td>
<td>6</td>
<td>11</td>
<td>16</td>
</tr>
</tbody>
</table>

\[
\begin{align*}
\text{if (64-bit mode)} & \quad \text{then } M \leftarrow 0 \\
\text{else } & \quad M \leftarrow 32 \\
\text{if } \neg BO_2 \text{ then } & \quad \text{CTR} \leftarrow \text{CTR} - 1 \\
\text{cond OK} & \quad \text{CTR}_0:61 \| 0b00 \\
\text{if LK then } & \quad LR \leftarrow \text{CIA + 4} \\
\end{align*}
\]

BI+32 specifies the Condition Register bit to be tested. The BO field is used to resolve the branch as described in Figure 40. The BH field is used as described in Figure 42. The branch target address is LR0:61 || 0b00, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the Branch instruction is placed into the Link Register.

**Special Registers Altered:**

CTR (if BO=0) 
LR (if LK=1)

**Extended Mnemonics:**

Examples of extended mnemonics for Branch Conditional to Link Register:

<table>
<thead>
<tr>
<th>Extended mnemonic</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>bclr 4,6</td>
<td>bclr 4,6,0</td>
</tr>
<tr>
<td>bltlr</td>
<td>bclr 12,0,0</td>
</tr>
<tr>
<td>bnelr cr2</td>
<td>bclr 4,10,0</td>
</tr>
<tr>
<td>bdnzl</td>
<td>bclr 16,0,0</td>
</tr>
</tbody>
</table>

**Programming Note**

*bclr*, *bclrl*, *bcctr*, and *bcctrl* each serve as both a basic and an extended mnemonic. The Assembler will recognize a *bclr*, *bclrl*, *bcctr*, or *bcctrl* mnemonic with three operands as the basic form, and a *bclr*, *bclrl*, *bcctr*, or *bcctrl* mnemonic with two operands as the extended form. In the extended form the BH operand is omitted and assumed to be 0b00.

---

**Branch Conditional to Count Register**

**XL-form**

<table>
<thead>
<tr>
<th>BO</th>
<th>BI</th>
<th>BH</th>
<th>LK</th>
</tr>
</thead>
<tbody>
<tr>
<td>19</td>
<td>6</td>
<td>11</td>
<td>16</td>

</tbody>
</table>

\[
\begin{align*}
\text{cond OK} & \quad \text{BO}_0 \| (\text{CRBI+32} = \text{BO}_2) \\
\text{if cond OK then } & \quad \text{NA} \leftarrow \text{CTR}_0:61 \| 0b00 \\
\text{if LK then } & \quad LR \leftarrow \text{CIA + 4} \\
\end{align*}
\]

BI+32 specifies the Condition Register bit to be tested. The BO field is used to resolve the branch as described in Figure 40. The BH field is used as described in Figure 42. The branch target address is CTR0:61 || 0b00, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the Branch instruction is placed into the Link Register.

If the “decrement and test CTR” option is specified (BO2=0), the instruction form is invalid.

**Special Registers Altered:**

LR (if LK=1)

**Extended Mnemonics:**

Examples of extended mnemonics for Branch Conditional to Count Register:

<table>
<thead>
<tr>
<th>Extended mnemonic</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>bcctr 4,6</td>
<td>bcctr 4,6,0</td>
</tr>
<tr>
<td>bctctr</td>
<td>bcctr 12,0,0</td>
</tr>
<tr>
<td>bctctr cr2</td>
<td>bcctr 4,10,0</td>
</tr>
</tbody>
</table>

---

*bcclr*, *bcclrl*, *bcctcr*, and *bcctcrl* each serve as both a basic and an extended mnemonic. The Assembler will recognize a *bcclr*, *bcclrl*, *bcctcr*, or *bcctcrl* mnemonic with three operands as the basic form, and a *bcclr*, *bcclrl*, *bcctcr*, or *bcctcrl* mnemonic with two operands as the extended form. In the extended form the BH operand is omitted and assumed to be 0b00.
### Branch Conditional to Branch Target

**Address Register XL-form**

<table>
<thead>
<tr>
<th>bctar</th>
<th>BO, BI, BH</th>
<th>(LK=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>bctarl</td>
<td>BO, BI, BH</td>
<td>(LK=1)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>19</th>
<th>BO</th>
<th>BI</th>
<th>/<em>BH</em>/</th>
<th>560</th>
<th>Lk</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>19</td>
<td>31</td>
</tr>
</tbody>
</table>

If (64-bit mode)
then M ← 1
else M ← 32
if ¬BO2 then CTR ← CTR − 1
ctr_ok ← BO2 | (CTR[M:63] ≠ 0) ⊕ BO3
cond_ok ← BO0 | (CRBI+32 ≡ BO1)
if ctr_ok & cond_ok then NIA ← iea TAR0:61 || 0b00
if LK then LR ← iea CIA + 4

BI+32 specifies the Condition Register bit to be tested. The BO field is used to resolve the branch as described in Figure 40. The BH field is used as described in Figure 42. The branch target address is TAR0:61 || 0b00, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the Branch instruction is placed into the Link Register.

**Special Registers Altered:**

- CTR (if BO2=0)
- LR (if LK=1)

---

**Programming Note**

In some systems, the system software will restrict usage of the `bctar` instruction to only selected programs. If an attempt is made to execute the instruction when it is not available, the system error handler will be invoked. See Book III for additional information.
2.5 Condition Register Instructions

2.5.1 Condition Register Logical Instructions

The Condition Register Logical instructions have preferred forms; see Section 1.8.1. In the preferred forms, the BT and BB fields satisfy the following rule.

- The bit specified by BT is in the same Condition Register field as the bit specified by BB.

Extended mnemonics for Condition Register logical operations

A set of extended mnemonics is provided that allow additional Condition Register logical operations, beyond those provided by the basic Condition Register Logical instructions, to be coded easily. Some of these are shown as examples with the Condition Register Logical instructions. See Appendix C for additional extended mnemonics.

### Condition Register AND XL-form

**crand** BT,BA,BB

<table>
<thead>
<tr>
<th>19</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>257</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>11</td>
<td>11</td>
<td>21</td>
<td>03</td>
</tr>
</tbody>
</table>

\[ CR_{BT+32} \leftarrow CR_{BA+32} \land CR_{BB+32} \]

The bit in the Condition Register specified by BA+32 is ANDed with the bit in the Condition Register specified by BB+32, and the result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**

\( CR_{BT+32} \)

### Condition Register OR XL-form

**cror** BT,BA,BB

<table>
<thead>
<tr>
<th>19</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>449</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>11</td>
<td>11</td>
<td>21</td>
<td>01</td>
</tr>
</tbody>
</table>

\[ CR_{BT+32} \leftarrow CR_{BA+32} \lor CR_{BB+32} \]

The bit in the Condition Register specified by BA+32 is ORed with the bit in the Condition Register specified by BB+32, and the result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**

\( CR_{BT+32} \)

### Condition Register NAND XL-form

**crnand** BT,BA,BB

\[ CR_{BT+32} \leftarrow \neg (CR_{BA+32} \land CR_{BB+32}) \]

### Condition Register XOR XL-form

**crxor** BT,BA,BB

\[ CR_{BT+32} \leftarrow CR_{BA+32} \oplus CR_{BB+32} \]

**Extended Mnemonics:**

Example of extended mnemonics for Condition Register OR:

**Extended mnemonic:** crmove \( B_x, B_y \)

**Equivalent to:** cror \( B_x, B_y, B_y \)

Example of extended mnemonics for Condition Register XOR:

**Extended mnemonic:** crclr \( B_x \)

**Equivalent to:** crxor \( B_x, B_x, B_x \)
**Condition Register NOR XL-form**

\[ \text{cmnor } \quad \text{BT,BA,BB} \]

<table>
<thead>
<tr>
<th>19</th>
<th>BT</th>
<th>BA</th>
<th>BB</th>
<th>33</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>

\[ C_{BT+32} \leftarrow \neg(\neg C_{BA+32} \lor \neg C_{BB+32}) \]

The bit in the Condition Register specified by BA+32 is ORed with the bit in the Condition Register specified by BB+32, and the complemented result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**

\[ C_{BT+32} \]

**Extended Mnemonics:**

Example of extended mnemonics for *Condition Register NOR*:

**Extended mnemonic:** \[ \text{crnot } \quad Bx,By \]

**Equivalent to:** \[ \text{crnor } \quad Bx,By,By \]

---

**Condition Register AND with Complement XL-form**

\[ \text{crandc } \quad \text{BT,BA,BB} \]

<table>
<thead>
<tr>
<th>19</th>
<th>BT</th>
<th>BA</th>
<th>BB</th>
<th>129</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>

\[ C_{BT+32} \leftarrow C_{BA+32} \land \neg C_{BB+32} \]

The bit in the Condition Register specified by BA+32 is ANDed with the complement of the bit in the Condition Register specified by BB+32, and the result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**

\[ C_{BT+32} \]

---

**Condition Register Equivalent XL-form**

\[ \text{creqv } \quad \text{BT,BA,BB} \]

<table>
<thead>
<tr>
<th>19</th>
<th>BT</th>
<th>BA</th>
<th>BB</th>
<th>289</th>
</tr>
</thead>

<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>

\[ C_{BT+32} \leftarrow C_{BA+32} = C_{BB+32} \]

The bit in the Condition Register specified by BA+32 is XORed with the bit in the Condition Register specified by BB+32, and the complemented result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**

\[ C_{BT+32} \]

**Extended Mnemonics:**

Example of extended mnemonics for *Condition Register Equivalent*:

**Extended mnemonic:** \[ \text{crset } \quad Bx \]

**Equivalent to:** \[ \text{creqv } \quad Bx,Bx,Bx \]

---

**Condition Register OR with Complement XL-form**

\[ \text{crorc } \quad \text{BT,BA,BB} \]

<table>
<thead>
<tr>
<th>19</th>
<th>BT</th>
<th>BA</th>
<th>BB</th>
<th>417</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>

\[ C_{BT+32} \leftarrow C_{BA+32} \lor \neg C_{BB+32} \]

The bit in the Condition Register specified by BA+32 is ORed with the complement of the bit in the Condition Register specified by BB+32, and the result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**

\[ C_{BT+32} \]
2.5.2 Condition Register Field Instruction

*Move Condition Register Field XL-form*

\[ \text{mcrf BF,BFA} \]

<table>
<thead>
<tr>
<th></th>
<th>19</th>
<th>BF</th>
<th>//</th>
<th>BFA</th>
<th>//</th>
<th>//</th>
<th>0</th>
<th>/</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>9</td>
<td>11</td>
<td>14</td>
<td>16</td>
<td>21</td>
<td>31</td>
<td></td>
</tr>
</tbody>
</table>

\[ CR_4 \times BF + 32 : 4 \times BF + 35 \]

The contents of Condition Register field BFA are copied to Condition Register field BF.

**Special Registers Altered:**
- CR field BF
2.6 System Call Instructions

These instructions provide the means by which a program can call upon the system to perform a service.

---

**System Call SC-form**

```
sc   LEV
```

These instructions call the system to perform a service. A complete description of these instructions can be found in Section 4.3.1 of Book III.

The first form of the instruction (sc) provides a single system call. The second form of the instruction (scv) provides the capability for 128 unique system calls.

The use of the LEV field is described in Book III. In the first form of the instruction the LEV values greater than 1 are reserved, and bits 0:5 of the LEV field (instruction bits 20:25) are treated as a reserved field.

When control is returned to the program that executed the System Call or System Call Vectored instruction, the contents of the registers will depend on the register conventions used by the program providing the system service.

These instructions are context synchronizing (see Book III).

**Special Registers Altered:**

Dependent on the system service

---

**Programming Note**

Since the scv instruction modifies the Count Register, programs should treat the contents of the Count Register as undefined after executing this instruction. See Section 4.3 of Book III.

---

**System Call Vectored SC-form**

```
scv  LEV
```

These instructions call the system to perform a service. A complete description of these instructions can be found in Section 4.3.1 of Book III.

The first form of the instruction (scv) provides the capability for 128 unique system calls.

The use of the LEV field is described in Book III. In the first form of the instruction the LEV values greater than 1 are reserved, and bits 0:5 of the LEV field (instruction bits 20:25) are treated as a reserved field.

When control is returned to the program that executed the System Call or System Call Vectored instruction, the contents of the registers will depend on the register conventions used by the program providing the system service.

These instructions are context synchronizing (see Book III).

**Special Registers Altered:**

Dependent on the system service

---

**Programming Note**

sc serves as both a basic and an extended mnemonic. The Assembler will recognize an sc mnemonic with one operand as the basic form, and an sc mnemonic with no operand as the extended form. In the extended form the LEV operand is omitted and assumed to be 0.

In application programs the value of the LEV operand for sc should be 0.
Chapter 3. Fixed-Point Facility

3.1 Fixed-Point Facility Overview

This chapter describes the registers and instructions that make up the Fixed-Point Facility.

3.2 Fixed-Point Facility Registers

3.2.1 General Purpose Registers

All manipulation of information is done in registers internal to the Fixed-Point Facility. The principal storage internal to the Fixed-Point Facility is a set of 32 General Purpose Registers (GPRs). See Figure 43.

<table>
<thead>
<tr>
<th>GPR 0</th>
<th>GPR 1</th>
<th>...</th>
<th>GPR 30</th>
<th>GPR 31</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Figure 43. General Purpose Registers

Each GPR is a 64-bit register.

3.2.2 Fixed-Point Exception Register

The Fixed-Point Exception Register (XER) is a 64-bit register.

<table>
<thead>
<tr>
<th>XER</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

Figure 44. Fixed-Point Exception Register

The bit definitions for the Fixed-Point Exception Register are shown below. Here M=0 in 64-bit mode and M=32 in 32-bit mode.

The bits are set based on the operation of an instruction considered as a whole, not on intermediate results (e.g., the Subtract From Carrying instruction, the result of which is specified as the sum of three values, sets bits in the Fixed-Point Exception Register based on the entire operation, not on an intermediate sum).

<table>
<thead>
<tr>
<th>Bit(s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0:31</td>
<td>Reserved</td>
</tr>
<tr>
<td>32</td>
<td>Summary Overflow (SO)</td>
</tr>
<tr>
<td></td>
<td>The Summary Overflow bit is set to 1 whenever an instruction (except mtspr and addex) sets the Overflow bit. Once set, the SO bit remains set until it is cleared by an mtspr instruction (specifying the XER). It is not altered by Compare instructions, by addex, or by other instructions (except mtspr to the XER) that cannot overflow. Executing an mtspr instruction to the XER, supplying the values 0 for SO and 1 for OV, causes SO to be set to 0 and OV to be set to 1.</td>
</tr>
<tr>
<td>33</td>
<td>Overflow (OV)</td>
</tr>
<tr>
<td></td>
<td>The Overflow bit is set to indicate that an overflow has occurred during execution of an instruction. The Overflow bit can also used as an independent Carry bit by using the addex with operand ( \top \equiv 0 ) instruction and avoiding other instructions that modify the Overflow bit (e.g., any XO-form instruction with ( \top \equiv 1 )). XO-form Add, Subtract From, and Negate instructions having ( \top \equiv 1 ) set it to 1 if the carry out of bit ( \top ) is not equal to the carry out of bit ( \top +1 ), and set it to 0 otherwise. XO-form Multiply Low and Divide instructions having ( \top \equiv 1 ) set it to 1 if the result cannot be represented in 64 bits (mulld, divd, divide, divdu, divdeu) or in 32 bits (mullw, divw, divwe, divwu, divweu), and set it to 0 otherwise.</td>
</tr>
</tbody>
</table>
addex with operand \(Y=0\) sets OV to 1 if there is a carry out of bit \(M\), and sets it to 0 otherwise.

The OV bit is not altered by Compare instructions, or by other instructions (except mt spr to the XER) that cannot overflow.

34 Carry (CA)
The Carry bit is set as follows, during execution of certain instructions. Add Carrying, Subtract From Carrying, Add Extended, and Subtract From Extended types of instructions set it to 1 if there is a carry out of bit \(M\), and set it to 0 otherwise. Shift Right Algebraic instructions set it to 1 if any 1-bits have been shifted out of a negative operand, and set it to 0 otherwise. The CA bit is not altered by Compare instructions, or by other instructions (except Shift Right Algebraic, mt spr to the XER) that cannot carry.

35:43 Reserved

44 Overflow32 (OV32)
OV32 is set whenever OV is implicitly set, and is set to the same value that OV is defined to be set to in 32-bit mode.

45 Carry32 (CA32)
CA32 is set whenever CA is implicitly set, and is set to the same value that CA is defined to be set to in 32-bit mode.

46:56 Reserved
Bits 48:55 are implemented, and can be read and written by software as if the bits contained a defined field.

57:63 This field specifies the number of bytes to be transferred by a Load String Indexed or Store String Indexed instruction.

### Programming Note

Bits 48:55 of the XER correspond to bits 16:23 of the XER in the POWER Architecture. In the POWER Architecture bits 16:23 of the XER contain the comparison byte for the **ls cbx** instruction. Power ISA lacks the **ls cbx** instruction, but some application programs that run on processors that implement Power ISA may still use **ls cbx**, and privileged software may emulate the instruction. XER\(_{48:55}\) may be assigned a meaning in a future version of the architecture, when POWER compatibility for **ls cbx** is no longer needed, so these bits should not be used for purposes other than the **ls cbx** comparison byte.

### 3.2.3 VR Save Register

The VR Save Register (VRSAVE) is a 32-bit register that can be used as a software use SPR; see Section 6.3.3.
3.3 Fixed-Point Facility Instructions

3.3.1 Fixed-Point Storage Access Instructions

The Storage Access instructions compute the effective address (EA) of the storage to be accessed as described in Section 1.10.3 on page 29.

**Programming Note**

The la extended mnemonic permits computing an effective address as a Load or Store instruction would, but loads the address itself into a GPR rather than loading the value that is in storage at that address.

3.3.1.1 Storage Access Exceptions

Storage accesses will cause the system data storage error handler to be invoked if the program is not allowed to modify the target storage (Store only), or if the program attempts to access storage that is unavailable.

3.3.2 Fixed-Point Load Instructions

The byte, halfword, word, or doubleword in storage addressed by EA is loaded into register RT.

Many of the Load instructions have an "update" form, in which register RA is updated with the effective address. For these forms, if RA≠0 and RA≠RT, the effective address is placed into register RA and the storage element (byte, halfword, word, or doubleword) addressed by EA is loaded into RT.

**Programming Note**

In some implementations, the Load Algebraic and Load with Update instructions may have greater latency than other types of Load instructions. Moreover, Load with Update instructions may take longer to execute in some implementations than the corresponding pair of a non-update Load instruction and an Add instruction.

</table>

EA ← (RA) + (RB)
RT ← MEM(EA, b)
RA ← EA

Let the effective address (EA) be the sum (RA) + (RB). The doubleword in storage addressed by EA is loaded into RT.

EA is placed into register RA.

If RA=0 or RA=RT, the instruction form is invalid.

**Special Registers Altered:**

None
3.3.3 Fixed-Point Store Instructions

The contents of register RS are stored into the byte, halfword, word, or doubleword in storage addressed by EA.

Many of the Store instructions have an “update” form, in which register RA is updated with the effective address. For these forms, the following rules apply.

- If RA≠0, the effective address is placed into register RA.
- If RS=RA, the contents of register RS are copied to the target storage element and then EA is placed into RA (RS).
**Store Byte D-form**

```
<table>
<thead>
<tr>
<th>38</th>
<th>RS</th>
<th>RA</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
</tr>
</tbody>
</table>
```

**Prefix: Store Byte MLS:D-form**

```
pstb  RS,D(RA),R
```

**Prefixed: Store Byte MLS:D-form**

Prefix:

```
<table>

3.3.4 Fixed Point Load and Store Quadword Instructions

For \( lq \), the quadword in storage addressed by \( EA \) is loaded into an even-odd pair of GPRs as follows. In Big-Endian mode, the even-numbered GPR is loaded with the doubleword from storage addressed by \( EA \) and the odd-numbered GPR is loaded with the doubleword addressed by \( EA + 8 \). In Little-Endian mode, the even-numbered GPR is loaded with the byte-reversed doubleword from storage addressed by \( EA + 8 \) and the odd-numbered GPR is loaded with the byte-reversed doubleword addressed by \( EA \).

On the other hand, for \( plq \), the quadword in storage addressed by \( EA \) is loaded into an even-odd pair of GPRs as follows. Independent of endian mode, the even-numbered GPR is loaded with the doubleword from storage addressed by \( EA \) and the odd-numbered GPR is loaded with the doubleword addressed by \( EA + 8 \).

In the preferred form of the \textit{Load Quadword} instruction \( RA \neq RTp+1 \).

For \( stq \), the contents of an even-odd pair of GPRs is stored into the quadword in storage addressed by \( EA \) as follows. In Big-Endian mode, the even-numbered GPR is stored into the doubleword in storage addressed by \( EA \) and the odd-numbered GPR is stored into the doubleword addressed by \( EA + 8 \). In Little-Endian mode, the even-numbered GPR is stored byte-reversed into the doubleword in storage addressed by \( EA + 8 \) and the odd-numbered GPR is stored byte-reversed into the doubleword addressed by \( EA \).

On the other hand, for \( pstq \), the contents of an even-odd pair of GPRs is stored into the quadword in storage addressed by \( EA \) as follows. Independent of endian mode, the even-numbered GPR is stored into the doubleword in storage addressed by \( EA \) and the odd-numbered GPR is stored into the doubleword addressed by \( EA + 8 \).

\textbf{Programming Note}

The \( lq \) and \( stq \) instructions exist primarily to permit software to access quadwords in storage "atomically"; see Section 1.4 of Book II. Because GPRs are 64 bits long, the Fixed-Point Facility on many designs is optimized for storage accesses of at most eight bytes. On such designs, the quadword atomicity required for \( lq \) and \( stq \) makes these instructions complex to implement, with the result that the instructions may perform less well on these designs than the corresponding two \textit{Load Doubleword} or \textit{Store Doubleword} instructions.

The complexity of providing quadword atomicity may be especially great for storage that is Write Through Required or Caching Inhibited (see Section 1.6 of Book II). This is why \( lq \) and \( stq \) are permitted to cause the data storage error handler to be invoked if the specified storage location is in either of these kinds of storage (see Section 3.3.1.1).
Load Quadword DQ-form

\[ \text{lq } \text{RTp, DQ(RA)} \]

<table>
<thead>
<tr>
<th>56</th>
<th>RTp</th>
<th>RA</th>
<th>DQ</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>6</td>
<td>11</td>
<td>16</td>
</tr>
</tbody>
</table>

Prefix:

<table>
<thead>
<tr>
<th>1</th>
<th>0</th>
<th>0</th>
<th>R</th>
<th>0</th>
<th>d0</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>6</td>
<td>9</td>
<td>11</td>
<td>12</td>
<td>14</td>
</tr>
</tbody>
</table>

Suffix:

<table>
<thead>
<tr>
<th>56</th>
<th>RTp</th>
<th>RA</th>
<th>d1</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>6</td>
<td>11</td>
<td>16</td>
</tr>
</tbody>
</table>

**Prefixed Load Quadword 8LS:D-form**

\[ \text{plq } \text{RTp, D(RA), R} \]

**Prefix:**

If “lq” then
\[ \text{EA} \leftarrow (\text{RA}|0) + \text{EXTS64(DQ)||0b0000} \]

If “plq” & R=0 then
\[ \text{EA} \leftarrow (\text{RA}|0) + \text{EXTS64(d0||d1)} \]

If “plq” & R=1 then
\[ \text{EA} \leftarrow \text{CIA} + \text{EXTS64(d0||d1)} \]

If Big-Endian byte ordering then
\[ \text{RTp}||\text{RTp+1} \leftarrow \text{MEM(EA,16)} \]

If “lq” and Little-Endian byte ordering then
\[ \text{RTp}||\text{RTp+1} \leftarrow \text{MEM(EA,16)} \]

If “plq” and Little-Endian byte ordering then
\[ \text{RTp+1}||\text{RTp} \leftarrow \text{MEM(EA,16)} \]

For **lq**, let the effective address (EA) be the sum of the contents of register RA, or the value 0 if RA=0, and the value DQ||0b0000, sign-extended to 64 bits.

For **plq** with R=0, let the effective address (EA) be the sum of the contents of register RA, or the value 0 if RA=0, and the value d0||d1, sign-extended to 64 bits.

For **plq** with R=1, let the effective address (EA) be the sum of the address of the instruction and the value d0||d1, sign-extended to 64 bits.

For Big-Endian byte ordering, the quadword in storage addressed by EA is loaded into RTp||RTp+1.

For Big-Endian byte ordering, the quadword in storage addressed by EA is byte-reversed and loaded into RTp||RTp+1.

For **lq** and Little-Endian byte ordering, the quadword in storage addressed by EA is byte-reversed and loaded into RTp||RTp.

For **plq** and Little-Endian byte ordering, the quadword in storage addressed by EA is byte-reversed and loaded into RTp||RTp.

If RTp is odd or RTp=RA, the instruction form is invalid. If RTp=RA, an attempt to execute this instruction will invoke the system illegal instruction error handler. (The RTp=RA case includes the case of RTp=RA=0.)

The quadword in storage addressed by EA is loaded into an even-odd pair of GPRs as follows. In Big-Endian mode, the even-numbered GPR is loaded with the doubleword from storage addressed by EA and the odd-numbered GPR is loaded with the doubleword addressed by EA+8. In Little-Endian mode, the even-numbered GPR is loaded with the byte-reversed doubleword from storage addressed by EA+8 and the odd-numbered GPR is loaded with the byte-reversed doubleword addressed by EA.

For **plq**, if R is equal to 1 and RA is not equal to 0, the instruction form is invalid.

**Programming Note**

In versions of the architecture prior to v2.07, this instruction was privileged.

**Special Registers Altered:**

None

**Extended Mnemonics:**

Extended mnemonics for **Prefixed Load Quadword**:

</tbody>
</table>

**Version 3.1**

Chapter 3. Fixed-Point Facility 65
Store Quadword DS-form

\[
\text{stq} \quad \text{RSp,} \text{DS(RA)}
\]

Prefix:

\[
\begin{array}{cccc}
0 & 6 & 11 & 16 \\
62 & 30 & 31 & 2
\end{array}
\]

Suffix:

\[
\begin{array}{cccc}
60 & 1 & 11 & 16 \\
62 & 0 & 6 & 14
\end{array}
\]

Prefix: 10 0 // R // d0 31

if “stq” then
EA ← (RA∥0) + EXTS64(DS∥0b00)
if “pstq” & R=0 then
EA ← (RA∥0) + EXTS64(d0∥d1)
if “pstq” & R=1 then
EA ← CIA + EXTS64(d0∥d1)
if Big-Endian byte ordering then
MEM(EA,16) ← |RSp|||RSp+1|
if “stq” and Little-Endian byte ordering then
MEM(EA,16) ← |RSp|||RSp+1|
if “pstq” and Little-Endian byte ordering then
MEM(EA,16) ← |RSp+1|||RSp|

For stq, let the effective address (EA) be the sum of the contents of register RA, or the value 0 if RA=0, and the value DS∥0b00, sign-extended to 64 bits.

For pstq with R=0, let the effective address (EA) be the sum of the contents of register RA, or the value 0 if RA=0, and the value d0∥d1, sign-extended to 64 bits.

For pstq with R=1, let the effective address (EA) be the sum of the address of the instruction and the value d0∥d1, sign-extended to 64 bits.

For Big-Endian byte ordering, the content of register pair RSp||RSp+1 is stored into the quadword in storage addressed by EA.

For Little-Endian byte ordering, the content of register pair RSp||RSp+1 is byte-reversed and stored into the quadword in storage addressed by EA.

For pstq and Little-Endian byte ordering, the content of register pair RSp+1||RSp is byte-reversed and stored into the quadword in storage addressed by EA.

If RSp is odd, the instruction form is invalid.

The contents of an even-odd pair of GPRs is stored into the quadword in storage addressed by EA as follows. In Big-Endian mode, the even-numbered GPR is stored into the doubleword in storage addressed by EA and the odd-numbered GPR is stored into the doubleword addressed by EA+8. In Little-Endian mode, the even-numbered GPR is stored byte-reversed into the doubleword in storage addressed by EA+8 and the odd-numbered GPR is stored byte-reversed into the doubleword addressed by EA.

For pstq, if R is equal to 1 and RA is not equal to 0, the instruction form is invalid.

Programming Note

In versions of the architecture prior to V. 2.07, this instruction was privileged.

Special Registers Altered:
None

Extended Mnemonics:

Extended mnemonics for Prefixed Store Quadword:

</table>

For stq and Little-Endian byte ordering, the content of register pair RSp+1||RSp is byte-reversed and stored into the quadword in storage addressed by EA.

Extended mnemonics for Prefixed Store Quadword:
3.3.5 Fixed-Point Load and Store with Byte Reversal Instructions

Load Halfword Byte-Reverse Indexed X-form

lhbrx RT, RA, RB

if RA = 0 then b ← 0
else b ← (RA)
EA ← b + (RB)
load_data ← MEM(EA, 2)
RT ← 480 || load_data8:15 || load_data0:7

Let the effective address (EA) be the sum (RA|0) + (RB).

Bits 0:7 of the halfword in storage addressed by EA are loaded into RT56:63.

Bits 8:15 of the halfword in storage addressed by EA are loaded into RT48:55.

RT0:47 are set to 0.

Special Registers Altered:
None

Programming Note
These instructions have the effect of loading and storing data in the opposite byte ordering from that which would be used by other Load and Store instructions.

Store Halfword Byte-Reverse Indexed X-form

sthbrx RS, RA, RB

if RA = 0 then b ← 0
else b ← (RA)
EA ← b + (RB)
MEM(EA, 2) ← (RS)56:63 || (RS)48:55

Let the effective address (EA) be the sum (RA|0) + (RB).

(RS)56:63 are stored into bits 0:7 of the halfword in storage addressed by EA.

(RS)48:55 are stored into bits 8:15 of the halfword in storage addressed by EA.

Special Registers Altered:
None

Programming Note
In some implementations, the Load Byte-Reverse instructions may have greater latency than other Load instructions.

3.3.6 Fixed-Point Load and Store Multiple Instructions

Load Multiple Word D-form

`lmw RT,D(RA)`

If `RA = 0` then `b ← 0` else `b ← |RA|`

`EA ← b + EXTS(D)`

`r ← RT`

Do while `r ≤ 31`

`GPR(r)32:63 ← MEM(EA, 4)`

`r ← r + 1`

`EA ← EA + 4`

Let `n = (32 - RT)`. Let the effective address (`EA`) be the sum `|RA|0 + D`.

`n` consecutive words starting at `EA` are loaded into the low-order 32 bits of GPRs `RT` through 31. The high-order 32 bits of these GPRs are set to zero.

If `RA` is in the range of registers to be loaded, including the case in which `RA=0`, the instruction form is invalid.

This instruction is not supported in Little-Endian mode. If it is executed in Little-Endian mode, the system alignment error handler is invoked.

Special Registers Altered:
None

Store Multiple Word D-form

`stmw RS,D(RA)`

If `RA = 0` then `b ← 0` else `b ← |RA|`

`EA ← b + EXTS(D)`

`r ← RS`

Do while `r ≤ 31`

`MEM(EA, 4) ← GPR(r)32:63`

`r ← r + 1`

`EA ← EA + 4`

Let `n = (32 - RS)`. Let the effective address (`EA`) be the sum `|RA|0 + D`.

`n` consecutive words starting at `EA` are stored from the low-order 32 bits of GPRs `RS` through 31.

This instruction is not supported in Little-Endian mode. If it is executed in Little-Endian mode, the system alignment error handler is invoked.

Special Registers Altered:
None
3.3.7 Fixed-Point Move Assist Instructions [Phased Out]

The *Move Assist* instructions allow movement of an arbitrary sequence of bytes from storage to registers or from registers to storage without concern for alignment. These instructions can be used for a short move between arbitrary storage locations or to initiate a long move between unaligned storage fields.

The *Move Assist* instructions have preferred forms; see Section 1.8.1, “Preferred Instruction Forms” on page 24. In the preferred forms, register usage satisfies the following rules.

- $\text{RS} = 4$ or $5$
- $\text{RT} = 4$ or $5$
- last register loaded/stored $\leq 12$

For some implementations, using GPR 4 for $\text{RS}$ and $\text{RT}$ may result in slightly faster execution than using GPR 5.
**Load String Word Immediate X-form**

**lswi**  
RT, RA, NB

<table>
<thead>
<tr>
<th>31</th>
<th>25</th>
<th>20</th>
<th>16</th>
<th>11</th>
<th>6</th>
<th>1</th>

  MEM(EA, 1) ← GPR(r)i:i+7
  i ← i + 8
  if i = 64 then i ← 32
  EA ← EA + 1
  n ← n - 1
endo

Let the effective address (EA) be the sum (RA|0) + (RB). Let n = XER57:63; n is the number of bytes to store. Let nr = CEIL(n/4); nr is the number of registers to supply data.

If n > 0, n consecutive bytes starting at EA are stored from GPRs RS through RS+nr-1. Data are stored from the low-order four bytes of each GPR.

Bytes are stored left to right from each register. The sequence of registers wraps around to GPR 0 if required.

If n = 0, no bytes are stored.

This instruction is not supported in Little-Endian mode. If it is executed in Little-Endian mode and n > 0, the system alignment error handler is invoked.

**Special Registers Altered:**

None
3.3.8 Other Fixed-Point Instructions

The remainder of the fixed-point instructions use the contents of the General Purpose Registers (GPRs) as source operands, and place results into GPRs, into the Fixed-Point Exception Register (XER), and into Condition Register fields. In addition, the Trap instructions test the contents of a GPR or XER bit, invoking the system trap handler if the result of the specified test is true.

These instructions treat the source operands as signed integers unless the instruction is explicitly identified as performing an unsigned operation.

The X-form and XO-form instructions with Rc=1, and the D-form instructions addic, andi, and andis, set the first three bits of CR Field 0 to characterize the result placed into the target register. In 64-bit mode, these bits are set by signed comparison of the result to zero. In 32-bit mode, these bits are set by signed comparison of the low-order 32 bits of the result to zero.

Unless otherwise noted and when appropriate, when CR Field 0 and the XER are set they reflect the value placed into the target register.

---

**Programming Note**

Instructions with the OE bit set or that set CA and CA32 may execute slowly or may prevent the execution of subsequent instructions until the instruction has completed.
3.3.9 Fixed-Point Arithmetic Instructions

The XO-form Arithmetic instructions with Rc=1, and the D-form Arithmetic instruction `addc`, set the first three bits of CR Field 0 as described in Section 3.3.8, “Other Fixed-Point Instructions”.

`addic`, `addic`, `subfic`, `addc`, `subfc`, `adde`, `subfe`, `addme`, `subfme`, `addze`, and `subfze` always set CA, to reflect the carry out of bit 0 in 64-bit mode and out of bit 32 in 32-bit mode. These instructions also always set CA32 to reflect the carry out of bit 32. The XO-form Arithmetic instructions set SO, OV, and OV32 when OE=1 to reflect overflow of the result. Except for the Multiply Low and Divide instructions, the setting of SO and OV is mode-dependent, and reflects overflow of the 64-bit result in 64-bit mode and overflow of the low-order 32-bit result in 32-bit mode, while OV32 reflects overflow of the low-order 32-bit result independent of the mode. For XO-form Multiply Low and Divide instructions, the setting of SO, OV, and OV32 is mode-independent, and reflects overflow of the 64-bit result for `mulld`, `divd`, `divde`, `divdu` and `divdeu`, and overflow of the low-order 32-bit result for `mullw`, `divw`, `divwe`, `divwu`, and `divweu`.

---

**Programming Note**

Notice that CR Field 0 may not reflect the “true” (infinitely precise) result if overflow occurs.

**Extended mnemonics for addition and subtraction**

Several extended mnemonics are provided that use the Add Immediate and Add Immediate Shifted instructions to load an immediate value or an address into a target register. Some of these are shown as examples with the two instructions.

The Power ISA supplies Subtract From instructions, which subtract the second operand from the third. A set of extended mnemonics is provided that use the more “normal” order, in which the third operand is subtracted from the second, with the third operand being either an immediate field or a register. Some of these are shown as examples with the appropriate Add and Subtract From instructions.

See Appendix C for additional extended mnemonics.
Add Immediate D-form

```
addi RT,RA,SI
```

Prefixed Add Immediate MLS:D-form

```
paddi RT,RA,SI,R
```

Prefix:  
Suffix:

```
if "addi" then
    RT ← (RA|0) + EXTS64(SI)
else
    RT ← (RA) + EXTS64(SI||si0
```

For `addi`, let the sum of the contents of register RA, or the value 0 if RA=0, and the value SI, sign-extended to 64 bits, is placed into register RT.

For `paddi` with R=0, the sum of the contents of register RA, or the value 0 if RA=0, and the value si0||si1, sign-extended to 64 bits, is placed into register RT.

For `paddi` with R=1, the sum of the address of the instruction and the value si0||si1, sign-extended to 64 bits, is placed into register RT.

For `paddi`, if R is equal to 1 and RA is not equal to 0, the instruction form is invalid.

<td>RB</td>
<td>CY</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If CY=0 then RT ← |RA| + |RB| + OV

For CY=0, the sum |RA| + |RB| + OV is placed into register RT.

For CY=0, OV is set to 1 if there is a carry out of bit 0 of the sum in 64-bit mode or there is a carry out of bit 32 of the sum in 32-bit mode, and set to 0 otherwise. OV32 is set to 1 if there is a carry out of bit 32 bit of the sum.

CY=1, CY=2, and CY=3 are reserved.

**Special Registers Altered:**

- OV
- OV32 (if CY=0)

---

**Programming Note**

An addc-equivalent instruction using OV is not provided. An equivalent capability can be emulated by first initializing OV to 0, then using addex. OV can be initialized to 0 using subfo, subtracting any operand from itself.

---

Negate XO-form

<td>16</td>
<td>212</td>
<td>11</td>
<td>31</td>
</tr>
</tbody>
</table>

\[\text{prod}_{0:63} \leftarrow (\text{RA})_{32:63} \times (\text{RB})_{32:63}\]

\[\text{RT}_{32:63} \leftarrow \text{prod}_{0:31}\]

\[\text{RT}_{0:31} \leftarrow \text{undefined}\]

The 32-bit operands are the low-order 32 bits of \(\text{RA}\) and \(\text{RB}\). The high-order 32 bits of the 64-bit product of the operands are placed into \(\text{RT}_{32:63}\). The contents of \(\text{RT}_{0:31}\) are undefined.

Both operands and the product are interpreted as unsigned integers, except that if \(\text{RC}=1\) the first three bits of CR Field 0 are set by signed comparison of the result to zero.

**Special Registers Altered:**
- CR0 (bits 0:2 undefined in 64-bit mode) (if \(\text{RC}=1\))
Divide Word XO-form

<table>
<thead>
<tr>
<th>31</th>
<th>RT</th>
<th>RA</th>
<th>RB</th>
<th>OE</th>
<th>RC</th>
<th>491</th>
<th>R3</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>22</td>
<td>31</td>
<td></td>
</tr>
</tbody>
</table>

\[
\text{dividend}_{0:31} \leftarrow (RA)_{32:63}
\]
\[
\text{divisor}_{0:31} \leftarrow (RB)_{32:63}
\]
\[
RT_{32:63} \leftarrow \text{dividend} \div \text{divisor}
\]
\[
RT_{0:31} \leftarrow \text{undefined}
\]

The 32-bit dividend is \((RA)_{32:63}\). The 32-bit divisor is \((RB)_{32:63}\). The 32-bit quotient is placed into \(RT_{32:63}\). The contents of \(RT_{0:31}\) are undefined. The remainder is not supplied as a result.

Both operands and the quotient are interpreted as signed integers. The quotient is the unique signed integer that satisfies

\[
\text{dividend} = (\text{quotient} \times \text{divisor}) + r
\]

where \(0 \leq r < \lvert \text{divisor} \rvert\) if the dividend is nonnegative, and \(-\lvert \text{divisor} \rvert < r \leq 0\) if the dividend is negative.

If an attempt is made to perform any of the divisions

\[
0 \times 0000_0000 + -1
\]
\[
<\text{anything}> + 0
\]

then the contents of register \(RT\) are undefined as are (if \(RC=1\)) the contents of the \(LT\), \(GT\), and \(EQ\) bits of CR Field 0. In these cases, if \(OE=1\) then OV and OV32 are set to 1.

Special Registers Altered:

- CR0 (bits 0:2 undefined in 64-bit mode) (if \(RC=1\))
- SO OV OV32 (if \(OE=1\))

Programming Note

The 32-bit signed remainder of dividing \((RA)_{32:63}\) by \((RB)_{32:63}\) can be computed as follows, except in the case that \((RA)_{32:63} = -2^{31}\) and \((RB)_{32:63} = -1\).

\[
\text{divw} \quad RT, RA, RB \quad \# \quad RT = \text{quotient}
\]
\[
\text{mullw} \quad RT, RT, RB \quad \# \quad RT = \text{quotient} \times \text{divisor}

\end{array}
\]

\[
\begin{array}{cccccccc}
\text{dividend} & \text{divisor} & \text{RT} & \text{RA} & \text{RB} & \text{OE} & \text{Rc}
\end{array}
\]

\[
\text{dividend} = (\text{quotient} \times \text{divisor}) + r
\]

where \(0 \leq r < |\text{divisor}|\).

If \(|\text{RA}| \geq |\text{RB}|\), or if an attempt is made to perform the division

\[
<\text{anything}> + 0
\]

then the contents of register RT are undefined as are (if Rc=1) the contents of the LT, GT, and EO bits of CR Field 0. In these cases, if OE=1 then OV and OV32 are set to 1.

**Special Registers Altered:**

- CR0 (bits 0:2 undefined in 64-bit mode) (if Rc=1)
- SO
- OV
- OV32 (if OE=1)
Unsigned long division of a 64-bit dividend contained in two 32-bit registers by a 32-bit divisor can be computed as follows. The algorithm is shown first, followed by Assembler code that implements the algorithm. The dividend is \( Dh || Dl \), the divisor is \( Dv \), and the quotient and remainder are \( Q \) and \( R \) respectively, where these variables and all intermediate variables represent unsigned 32-bit integers. It is assumed that \( Dv > Dh \), and that assigning a value to an intermediate variable assigns the low-order 32 bits of the value and ignores any higher-order bits of the value. (In both the algorithm and the Assembler code, "r1" and "r2" refer to "remainder 1" and "remainder 2", rather than to GPRs 1 and 2.)

Algorithm:

3. \( q1 \leftarrow \text{divweu } Dh, Dv \) # remainder of step 1
divide operation (see Note 1)
4. \( r1 \leftarrow -(q1 \times Dv) \) # remainder of step 1
divide operation
5. \( q2 \leftarrow \text{divwu } Dl, Dv \) # remainder of step 2
divide operation
6. \( r2 \leftarrow Dl - (q2 \times Dv) \) # remainder of step 2
7. \( Q \leftarrow q1 + q2 \)
8. \( R \leftarrow r1 + r2 \)
9. if \( (R < r2) \) \( (R \geq Dv) \) then # (see Note 2)

   Q \leftarrow Q + 1 # increment quotient
   R \leftarrow R - Dv # decrement rem'der

Assembler Code:

```assembly
# Dh in r4, Dl in r5
# Dv in r6
divweu r3,r4,r6  # q1
divwu r7,r5,r6  # q2
mullw r8,r3,r6  # r1 = q1 * Dv
mullw r0,r7,r6  # r2 = q2 * Dv
subf r10,r0,r5  # r2 = Dl - (q2 * Dv)
add r3,r3,r7    # Q = q1 + q2
subf r4,r8,r10  # R = r1 + r2
cmplw r4,r10    # R < r2 ?
b1t *+12        # must adjust Q and R if yes
cmplw r4,r6     # R \geq Dv ?
b1t *+12        # must adjust Q and R if yes
addi r3,r3,1    # Q = Q + 1
subf r4,r6,r4    # R = R - Dv
# Quotient in r3
# Remainder in r4
```

Notes:

1. The remainder is \( Dh || 32^{32} \times (q1 \times Dv) \). Because the remainder must be less than \( Dv \) and \( Dv < 2^{32} \), the remainder is representable in 32 bits. Because the low-order 32 bits of \( Dh || 32^{32} \times q1 \) are 0s, the remainder is therefore equal to the low-order 32 bits of \( (q1 \times Dv) \). Thus assigning \( (q1 \times Dv) \) to \( r1 \) yields the correct remainder.

2. \( R \) is less than \( r2 \) (and also less than \( r1 \)) if and only if the addition at step 6 carried out of 32 bits — i.e., if and only if the correct sum could not be represented in 32 bits — in which case the correct sum is necessarily greater than \( Dv \).

Modulo Signed Word X-form

modsw RT,RA,RB

31  RT  RA  RB  779
 /|
3  4  11  16  21

\[ \text{dividend}_{31} \leftarrow (RA)_{32:63} \]
\[ \text{divisor}_{31} \leftarrow (RB)_{32:63} \]
\[ RT_{32:63} \leftarrow \text{dividend} \% \text{divisor} \]
\[ RT_{0:31} \leftarrow \text{undefined} \]

The 32-bit dividend is \((RA)_{32:63}\). The 32-bit divisor is \((RB)_{32:63}\). The 32-bit remainder of the dividend divided by the divisor is placed into \(RT_{32:63}\). The contents of \(RT_{0:31}\) are undefined. The quotient is not supplied as a result.

Both operands and the remainder are interpreted as signed integers. The remainder is the unique signed integer that satisfies

\[ \text{remainder} = \text{dividend} - (\text{quotient} \times \text{divisor}) \]

where \(0 \leq \text{remainder} < |\text{divisor}|\) if the dividend is nonnegative, and \(-|\text{divisor}| < \text{remainder} \leq 0\) if the dividend is negative.

If an attempt is made to perform any of the divisions

\[ 0x8000_0000 \% -1 \]
\[ <\text{anything}> \% 0 \]

then the contents of register \(RT\) are undefined.

Special Registers Altered:

None

</tbody>
</table>

RT ← random(L)

A random number is placed into register RT in a format selected by L as shown in the following table. The value 0xFFFFFFFF_FFFFFFFF indicates an error condition. For L=0, the random number range is 0:0xFFFFFFFF. For L=1 and L=2, the random number range is 0:0xFFFF_FFFFFFFE.

Special Registers Altered:

none

Programming Note

The random number generator provided by this instruction is NIST SP800-90B and SP800-90C compliant to the extent possible given the completeness of the standards at the time the hardware is designed. The random number generator provides a minimum of 0.5 bits of entropy per bit.

Programming Note

32-bit software running in an environment that does not preserve the high-order 32 bits of GPRs across invocations of the system error handler, signal handlers, event-based branch handlers, etc. may use the L=0 variant of darn and interpret the value 0xFFFFFFFF to indicate an error condition. The fact that the error condition includes the valid value 0x00000000_FFFFFFFF together with the true error value 0xFFFFFFFF_FFFFFFFF is not a problem.

Programming Note

When the error value is obtained, software is expected to repeat the operation. If a non-error value has not been obtained after several attempts, a software random number generation method should be used. The recommended number of attempts may be implementation specific. In the absence of other guidance, ten attempts should be adequate.
3.3.9.1 64-bit Fixed-Point Arithmetic Instructions

**Multiply Low Doubleword XO-form**

- `mulid` RT,RA,RB \( (OE=0 \quad Rc=0) \)
- `mulid.` RT,RA,RB \( (OE=0 \quad Rc=1) \)
- `mulido` RT,RA,RB \( (OE=1 \quad Rc=0) \)
- `mulido.` RT,RA,RB \( (OE=1 \quad Rc=1) \)

\[
\begin{array}{cccccc}
31 & 6 & 11 & 16 & 21 & 22 & 31 \\
\text{prod}_0:127 & \leftarrow (RA) \times (RB) \\
\text{RT} & \leftarrow \text{prod}_0:63
\end{array}
\]

The 64-bit operands are (RA) and (RB). The low-order 64 bits of the 128-bit product of the operands are placed into register RT.

If OE=1 then OV and OV32 are set to 1 if the product cannot be represented in 64 bits.

Both operands and the product are interpreted as signed integers.

**Special Registers Altered:**

- CR0 (if \( Rc=1 \))
- SO OV OV32 (if \( OE=1 \))

**Programming Note**

The XO-form Multiply instructions may execute faster on some implementations if RB contains the operand having the smaller absolute value.

**Multiply High Doubleword XO-form**

- `mulhd` RT,RA,RB \( (Rc=0) \)
- `mulhd.` RT,RA,RB \( (Rc=1) \)

\[
\begin{array}{ccccccc}
31 & 6 & 11 & 16 & 21 & 22 & 31 \\
\text{prod}_0:127 & \leftarrow (RA) \times (RB) \\
\text{RT} & \leftarrow \text{prod}_0:63
\end{array}
\]

The 64-bit operands are (RA) and (RB). The high-order 64 bits of the 128-bit product of the operands are placed into register RT.

Both operands and the product are interpreted as signed integers.

**Special Registers Altered:**

- CR0 (if \( Rc=1 \))

**Multiply High Doubleword Unsigned XO-form**

- `mulhdu` RT,RA,RB \( (Rc=0) \)
- `mulhdu.` RT,RA,RB \( (Rc=1) \)

\[
\begin{array}{ccccccc}
31 & 6 & 11 & 16 & 21 & 22 & 31 \\
\text{prod}_0:127 & \leftarrow (RA) \times (RB) \\
\text{RT} & \leftarrow \text{prod}_0:63
\end{array}
\]

The 64-bit operands are (RA) and (RB). The high-order 64 bits of the 128-bit product of the operands are placed into register RT.

Both operands and the product are interpreted as unsigned integers, except that if \( Rc=1 \) the first three bits of CR Field 0 are set by signed comparison of the result to zero.

**Special Registers Altered:**

- CR0 (if \( Rc=1 \))
### Multiply-Add High Doubleword VA-form

```
maddhd RT, RA, RB, RC
```

<table>
<thead>
<tr>
<th></th>
<th>RT</th>
<th>RA</th>
<th>RB</th>
<th>RC</th>
<th>48</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>26</td>
</tr>
</tbody>
</table>

\[
\begin{align*}
\text{prod}_{0:127} & \leftarrow (RA) \times (RB) \\
\text{sum}_{0:127} & \leftarrow \text{prod} + \text{EXTS}(RC) \\
\text{RT} & \leftarrow \text{sum}_{0:63}
\end{align*}
\]

The 64-bit operands are \( (RA), (RB), \) and \( (RC) \). The 128-bit product of the operands \( (RA) \) and \( (RB) \) is added to \( (RC) \). The high-order 64 bits of the 128-bit sum are placed into register \( \text{RT} \).

All three operands and the result are interpreted as signed integers.

**Special Registers Altered:**

None

### Multiply-Add High Doubleword Unsigned VA-form

```
maddhdu RT, RA, RB, RC
```

<table>
<thead>
<tr>
<th></th>
<th>RT</th>
<th>RA</th>
<th>RB</th>
<th>RC</th>
<th>49</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>26</td>
</tr>
</tbody>
</table>

\[
\begin{align*}
\text{prod}_{0:127} & \leftarrow |RA| \times |RB| \\
\text{sum}_{0:127} & \leftarrow \text{prod} + \text{EXTZ}(RC) \\
\text{RT} & \leftarrow \text{sum}_{0:63}
\end{align*}
\]

The 64-bit operands are \( |RA|, |RB|, \) and \( |RC| \). The 128-bit product of the operands \( |RA| \) and \( |RB| \) is added to \( |RC| \). The high-order 64 bits of the 128-bit sum are placed into register \( \text{RT} \).

All three operands and the result are interpreted as unsigned integers.

**Special Registers Altered:**

None

### Multiply-Add Low Doubleword VA-form

```
maddld RT, RA, RB, RC
```

<table>
<thead>
<tr>
<th></th>
<th>RT</th>
<th>RA</th>
<th>RB</th>
<th>RC</th>
<th>51</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>26</td>
</tr>
</tbody>
</table>

\[
\begin{align*}
\text{prod}_{0:127} & \leftarrow (RA) \times (RB) \\
\text{sum}_{0:127} & \leftarrow \text{prod} + \text{EXTS}(RC) \\
\text{RT} & \leftarrow \text{sum}_{64:127}
\end{align*}
\]

The 64-bit operands are \( (RA), (RB), \) and \( (RC) \). The 128-bit product of the operands \( (RA) \) and \( (RB) \) is added to \( (RC) \). The low-order 64 bits of the 128-bit sum are placed into register \( \text{RT} \).

All three operands and the result are interpreted as signed integers.

**Special Registers Altered:**

None
### Divide Doubleword XO-form

**Dividend**: 
\[ (RA) \]

**Divisor**: 
\[ (RB) \]

The 64-bit dividend is \((RA)\). The 64-bit divisor is \((RB)\). The 64-bit quotient is placed into register \(RT\). The remainder is not supplied as a result.

Both operands and the quotient are interpreted as signed integers. The quotient is the unique signed integer that satisfies

\[
dividend = \text{quotient} \times \text{divisor} + r
\]

where \(0 \leq r < |\text{divisor}|\) if the dividend is nonnegative, and \(-|\text{divisor}| < r \leq 0\) if the dividend is negative.

If an attempt is made to perform any of the divisions

\[
\begin{align*}
0\times8000_0000_0000_0000 & \div -1 \\
<\text{anything}> & \div 0
\end{align*}
\]

then the contents of register \(RT\) are undefined as are (if \(Rc=1\)) the contents of the LT, GT, and EQ bits of CR Field 0. In these cases, if \(OE=1\) then OV and OV32 are set to 1.

**Special Registers Altered:**

- \(CR0\) (if \(Rc=1\))
- \(SO\) \(OV\) \(OV32\) (if \(OE=1\))

**Programming Note**

The 64-bit signed remainder of dividing \((RA)\) by \((RB)\) can be computed as follows, except in the case that \((RA) = -2^{63}\) and \((RB) = -1\).

\[
\begin{align*}
divd & \quad RT,RA,RB \quad \# RT = \text{quotient} \\
\text{mulld} & \quad RT,RT,RB \quad \# RT = \text{quotient} \times \text{divisor} \\
\text{subf} & \quad RT,RT,RA \quad \# RT = \text{remainder}
\end{align*}
\]
**Divide Doubleword Extended XO-form**

| divide     | RT,RA,RB | OE=0 Rc=0 |
| divide.    | RT,RA,RB | OE=0 Rc=1 |
| divideo    | RT,RA,RB | OE=1 Rc=0 |
| divideuo   | RT,RA,RB | OE=1 Rc=1 |

\[
\begin{array}{cccccc}
  31 & 30 & 29 & 28 & 27 & 26 & 25 \\
  6 & 11 & 16 & 21 & 22 & 23 & 31 \\
\end{array}
\]

\[
\text{dividend}_0\leftarrow (RA) || 640 \\
\text{divisor}_0\leftarrow (RB) \\
RT\leftarrow \text{dividend} + \text{divisor}
\]

The 128-bit dividend is \(|RA| || 640\). The 64-bit divisor is \(|RB|\). If the quotient can be represented in 64 bits, it is placed into register \(RT\). The remainder is not supplied as a result.

Both operands and the quotient are interpreted as signed integers. The quotient is the unique signed integer that satisfies

\[
\text{dividend} = (\text{quotient} \times \text{divisor}) + r
\]

where \(0 \leq r < |\text{divisor}|\) if the dividend is nonnegative, and \(|\text{divisor}| < r \leq 0\) if the dividend is negative.

If the quotient cannot be represented in 64 bits, or if an attempt is made to perform the division

\[
\text{<anything>} + 0
\]

then the contents of register \(RT\) are undefined as are (if \(Rc=1\)) the contents of the LT, GT, and EQ bits of CR Field 0. In these cases, if \(OE=1\) then OV and OV32 are set to 1.

**Special Registers Altered:**

- CR0
- SO
- OV
- OV32

\(\text{if } Rc=1\)

\(\text{if } OE=1\)

**Divide Doubleword Extended Unsigned XO-form**

| divideu   | RT,RA,RB | OE=0 Rc=0 |
| divideu.  | RT,RA,RB | OE=0 Rc=1 |
| divideuo  | RT,RA,RB | OE=1 Rc=0 |
| divideuao | RT,RA,RB | OE=1 Rc=1 |

\[
\begin{array}{cccccc}
  31 & 30 & 29 & 28 & 27 & 26 & 25 \\
  6 & 11 & 16 & 21 & 22 & 23 & 31 \\
\end{array}
\]

\[
\text{dividend}_0\leftarrow (RA) || 640 \\
\text{divisor}_0\leftarrow (RB) \\
RT\leftarrow \text{dividend} + \text{divisor}
\]

The 128-bit dividend is \(|RA| || 640\). The 64-bit divisor is \(|RB|\). If the quotient can be represented in 64 bits, it is placed into register \(RT\). The remainder is not supplied as a result.

Both operands and the quotient are interpreted as unsigned integers, except that if \(Rc=1\) the first three bits of CR Field 0 are set by signed comparison of the result to zero. The quotient is the unique unsigned integer that satisfies

\[
\text{dividend} = (\text{quotient} \times \text{divisor}) + r
\]

where \(0 \leq r < \text{divisor}\).

If \(|RA| \geq |RB|\), or if an attempt is made to perform the division

\[
\text{<anything>} + 0
\]

then the contents of register \(RT\) are undefined as are (if \(Rc=1\)) the contents of the LT, GT, and EQ bits of CR Field 0. In these cases, if \(OE=1\) then OV and OV32 are set to 1.

**Special Registers Altered:**

- CR0
- SO
- OV
- OV32

\(\text{if } Rc=1\)

\(\text{if } OE=1\)

**Programming Note**

Unsigned long division of a 128-bit dividend contained in two 64-bit registers by a 64-bit divisor can be accomplished using the technique described in the Programming Note with the \texttt{divweu} instruction description: \texttt{divd[e]} would be used instead of \texttt{divw[e]} (and \texttt{cmpld} instead of \texttt{cmplw}, etc.).
**Modulo Signed Doubleword X-form**

\[ \text{modsd} \quad RT, RA, RB \]

<table>
<thead>
<tr>
<th>31</th>
<th>RT</th>
<th>RA</th>
<th>RB</th>
<th>777</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>

\[
\text{dividend} \leftarrow (RA) \\
\text{divisor} \leftarrow (RB) \\
RT \leftarrow \text{dividend} \% \text{divisor}
\]

The 64-bit dividend is \((RA)\). The 64-bit divisor is \((RB)\). The 64-bit remainder of the dividend divided by the divisor is placed into register \(RT\). The quotient is not supplied as a result.

Both operands and the remainder are interpreted as signed integers. The remainder is the unique signed integer that satisfies

\[
\text{remainder} = \text{dividend} - (\text{quotient} \times \text{divisor})
\]

where \(0 \leq \text{remainder} < |\text{divisor}|\) if the dividend is nonnegative, and \(-|\text{divisor}| < \text{remainder} \leq 0\) if the dividend is negative.

If an attempt is made to perform any of the divisions

\[
\text{<anything>} \% 0 \\
\text{0x8000_0000_0000_0000} \% -1
\]

then the contents of register \(RT\) are undefined.

**Special Registers Altered:**

None

---

**Modulo Unsigned Doubleword X-form**

\[ \text{modud} \quad RT, RA, RB \]

<table>
<thead>
<tr>
<th>31</th>
<th>RT</th>
<th>RA</th>
<th>RB</th>
<th>265</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>

\[
\text{dividend} \leftarrow (RA) \\
\text{divisor} \leftarrow (RB) \\
RT \leftarrow \text{dividend} \% \text{divisor}
\]

The 64-bit dividend is \((RA)\). The 64-bit divisor is \((RB)\). The 64-bit remainder of the dividend divided by the divisor is placed into register \(RT\). The quotient is not supplied as a result.

Both operands and the remainder are interpreted as unsigned integers. The remainder is the unique signed integer that satisfies

\[
\text{remainder} = \text{dividend} - (\text{quotient} \times \text{divisor})
\]

where \(0 \leq \text{remainder} < \text{divisor}\).

If an attempt is made to perform any of the divisions

\[
\text{<anything>} \% 0
\]

then the contents of register \(RT\) are undefined.

**Special Registers Altered:**

None
3.3.10 Fixed-Point Compare Instructions

The fixed-point \textit{Compare} instructions compare the contents of register RA with (1) the sign-extended value of the SI field, (2) the zero-extended value of the UI field, or (3) the contents of register RB. The comparison is signed for \textit{cmpi} and \textit{cmp}, and unsigned for \textit{cmpli} and \textit{cmpl}.

The L field controls whether the operands are treated as 64-bit or 32-bit quantities, as follows:

\begin{tabular}{ll}
L & Operand length \\
0 & 32-bit operands \\
1 & 64-bit operands \\
\end{tabular}

When the operands are treated as 32-bit signed quantities, bit 32 of the register (RA or RB) is the sign bit.

The \textit{Compare} instructions set one bit in the leftmost three bits of the designated CR field to 1, and the other two to 0. XER$_{SO}$ is copied to bit 3 of the designated CR field.

The CR field is set as follows:

<table>
<thead>
<tr>
<th>Bit Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>LT ($</td>
</tr>
<tr>
<td>1</td>
<td>GT ($</td>
</tr>
<tr>
<td>2</td>
<td>EQ ($</td>
</tr>
<tr>
<td>3</td>
<td>SO Summary Overflow from the XER</td>
</tr>
</tbody>
</table>

Extended mnemonics for compares

A set of extended mnemonics is provided so that compares can be coded with the operand length as part of the mnemonic rather than as a numeric operand. Some of these are shown as examples with the \textit{Compare} instructions. See Appendix C for additional extended mnemonics.
**Compare Immediate D-form**

\[ \text{cmpi } BF, L, RA, SI \]

<table>
<thead>
<tr>
<th>BF</th>
<th>L</th>
<th>RA</th>
<th>SI</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>6</td>
<td>16</td>
<td>31</td>
</tr>
</tbody>
</table>

if \( L = 0 \) then \( a \leftarrow \text{EXTS}(RA)_{32:63} \)
else \( a \leftarrow RA \)
if \( a < \text{EXTS}(SI) \) then \( c \leftarrow 0b100 \)
else if \( a > \text{EXTS}(SI) \) then \( c \leftarrow 0b010 \)
else \( c \leftarrow 0b001 \)

\[ \text{CR4} \times BF+32:4 \times BF+35 \leftarrow c || XERSO \]

The contents of register \( RA \) \((RA)_{32:63}\) sign-extended to 64 bits if \( L = 0 \) are compared with the sign-extended value of the \( SI \) field, treating the operands as signed integers. The result of the comparison is placed into CR field \( BF \).

**Special Registers Altered:**
CR field \( BF \)

**Extended Mnemonics:**

Examples of extended mnemonics for Compare Immediate:

- cmpdi Rx, value
- cmpi 0,1, Rx, value
- cmpldi Rx, value
- cmpli 0,1, Rx, value

**Compare Logical Immediate D-form**

\[ \text{cmpli } BF, L, RA, UI \]

<table>
<thead>
<tr>
<th>BF</th>
<th>L</th>
<th>RA</th>
<th>UI</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>6</td>
<td>16</td>
<td>31</td>
</tr>
</tbody>
</table>

if \( L = 0 \) then \( a \leftarrow 320 || (RA)_{32:63} \)
else \( a \leftarrow (RA) \)
if \( a < 480 || UI \) then \( c \leftarrow 0b100 \)
else if \( a > 480 || UI \) then \( c \leftarrow 0b010 \)
else \( c \leftarrow 0b001 \)

\[ \text{CR4} \times BF+32:4 \times BF+35 \leftarrow c || XERSO \]

The contents of register \( RA \) \((RA)_{32:63}\) zero-extended to 64 bits if \( L = 0 \) are compared with \( 480 || UI \), treating the operands as unsigned integers. The result of the comparison is placed into CR field \( BF \).

**Special Registers Altered:**
CR field \( BF \)

**Extended Mnemonics:**

Examples of extended mnemonics for Compare Logical Immediate:

- cmpldi Rx, value
- cmpli 0,1, Rx, value
- cmplw cr3, Rx, value
- cmpli 3,0, Rx, value

**Compare Logical X-form**

\[ \text{cmp } BF, L, RA, RB \]

<table>
<thead>
<tr>
<th>BF</th>
<th>L</th>
<th>RA</th>
<th>RB</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>6</td>
<td>16</td>
<td>21</td>
<td>31</td>
</tr>
</tbody>
</table>

if \( L = 0 \) then \( a \leftarrow 320 || (RA)_{32:63} \)
else \( a \leftarrow (RA) \)
if \( a < (RB)_{32:63} \) then \( c \leftarrow 0b100 \)
else if \( a > (RB)_{32:63} \) then \( c \leftarrow 0b010 \)
else \( c \leftarrow 0b001 \)

\[ \text{CR4} \times BF+32:4 \times BF+35 \leftarrow c || XERSO \]

The contents of register \( RA \) \((RA)_{32:63}\) are compared with the contents of register \( RB \) \((RB)_{32:63}\) if \( L = 0 \), treating the operands as unsigned integers. The result of the comparison is placed into CR field \( BF \).

**Special Registers Altered:**
CR field \( BF \)

**Extended Mnemonics:**

Examples of extended mnemonics for Compare Logical:

- cmpld Rx, Ry
- cmpd 0,1, Rx, Ry
- cmplw cr3, Rx, Ry
- cmpli 3,0, Rx, Ry

**Chapter 3. Fixed-Point Facility**
### 3.3.10.1 Character-Type Compare Instructions

#### Compare Ranged Byte X-form

**cmprb** \(BF, L, RA, RB\)

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>BF</th>
<th>L</th>
<th>RA</th>
<th>RB</th>
<th>192</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td>6</td>
<td>10</td>
<td>16</td>
<td>21</td>
<td>21</td>
</tr>
</tbody>
</table>

- **src1** ← EXTZ((RA)56:63)
- **src21hi** ← EXTZ((RB)32:39)
- **src21lo** ← EXTZ((RB)40:47)
- **src22hi** ← EXTZ((RB)48:55)
- **src22lo** ← EXTZ((RB)56:63)

if \(L=0\) then
  \[\text{in\_range} \leftarrow (\text{src22lo} \leq \text{src1}) \land (\text{src1} \leq \text{src22hi})\]
else
  \[\text{in\_range} \leftarrow (\text{src21lo} \leq \text{src1}) \land (\text{src1} \leq \text{src21hi}) \lor \text{in\_range} \leftarrow (\text{src22lo} \leq \text{src1}) \land (\text{src1} \leq \text{src22hi})\]

\[\text{CR}_{4\times BF+32:4\times BF+35} \leftarrow 0b0 || \text{in\_range} || 0b00\]

Let **src1** be the unsigned integer value in bits 56:63 of register RA.

Let **src21hi** be the unsigned integer value in bits 32:39 of register RB.

Let **src21lo** be the unsigned integer value in bits 40:47 of register RB.

Let **src22hi** be the unsigned integer value in bits 48:55 of register RB.

Let **src22lo** be the unsigned integer value in bits 56:63 of register RB.

Let \(x\) be considered “in range” of \(y:z\) if the value \(x\) is greater than or equal to the value \(y\) and the value \(x\) is less than or equal to the value \(z\).

When \(L=0\), the value \(\text{in\_range}\) is set to 1 if **src1** is in range of **src22lo**:**src22hi**. Otherwise, the value \(\text{in\_range}\) is set to 0.

When \(L=1\), the value \(\text{in\_range}\) is set to 1 if either **src1** is in range of **src21lo**:**src21hi**, or **src1** is in range of **src22lo**:**src22hi**. Otherwise, the value \(\text{in\_range}\) is set to 0.

**CR** field \(BF\) is set to the value \(0b0\) concatenated with \(\text{in\_range}\) concatenated with \(0b00\).

**Special Registers Altered:**

**CR** field \(BF\)

---

**Programming Note**

**cmprb** is useful for implementing character typing functions such as \(\text{isalpha}()\), \(\text{isdigit}()\), \(\text{isupper}()\), and \(\text{islower}()\) that are implemented using one or two range compares of the character.

A single-range compare can be implemented with an \(\text{addi}\) to load the upper and lower bounds in the range, such as \(\text{isdigit}()\).

```asm
addi    rRNG,0,0x3930    ; loads ASCII values for '9' 
&;  and '0' into rRNG
cmprb   crTGT,0,rCHAR,rRNG  ; perform range compare 
&;   sets CR field TGT to  ; indicate in range
```

A combination of \(\text{addi-\text{addis}}\) can be used to set up 2 ranges, such as for \(\text{isalpha}()\).

```asm
addi    rRNG,0,0x7A61    ; loads ASCII values for 'z' 
&;   and 'a' into rRNG
addis   rRNG,rRNG,0x5A41    ; appends ASCII values for 'Z' 
&;   and 'A' into rRNG
cmprb   crTGT,1,rCHAR,rRNG  ; perform range compare on 
&;   character in rCHAR,  ; indicate in range
```

---

**Let** **src1** be the unsigned integer value in bits 56:63 of register RA.

**Let** **src21hi** be the unsigned integer value in bits 32:39 of register RB.

**Let** **src21lo** be the unsigned integer value in bits 40:47 of register RB.

**Let** **src22hi** be the unsigned integer value in bits 48:55 of register RB.

**Let** **src22lo** be the unsigned integer value in bits 56:63 of register RB.

**Let** \(x\) be considered “in range” of \(y:z\) if the value \(x\) is greater than or equal to the value \(y\) and the value \(x\) is less than or equal to the value \(z\).

When \(L=0\), the value **in\_range** is set to 1 if **src1** is in range of **src22lo**:**src22hi**. Otherwise, the value **in\_range** is set to 0.

When \(L=1\), the value **in\_range** is set to 1 if either **src1** is in range of **src21lo**:**src21hi**, or **src1** is in range of **src22lo**:**src22hi**. Otherwise, the value **in\_range** is set to 0.

**CR** field **BF** is set to the value **0b0** concatenated with **in\_range** concatenated with **0b00**.
**Compare Equal Byte X-form**

\( (src1 = (RB)48:55) \)
\( (src1 = (RB)56:63) \)

\( CR4\times BF+32:4\times BF+35 \leftarrow 0b0 || match || 0b10 \)

The `BF` field is set to indicate if the contents of bits 56:63 of register `RA` are equal to the contents of any of the 8 bytes in register `RB`. Results are undefined in 32-bit mode.

**Special Registers Altered:**

- CR field BF

---

**Programming Note**

`cmpeqb` is useful for implementing character typing functions such as `isspace()` that are implemented by comparing the character to 1 or more values.

A function such as `isspace()` can be implemented by loading the 6 byte codes corresponding to characters considered as whitespace (HT, LF, VT, FF, CR, and SP) and using the `cmpeb` to compare the subject character to those 6 values to determine if any match occurs.

```assembly
ldx rSPC, WS_CHARS ; rSPC = 0x0909_090A_0B0C_0D20
            ; load rSPC with all 6 ASCII values corresponding to
            ; white spaces
            ; perform match compare on
            ; character in rCHAR with
            ; byte values in rSPC
```

In this case, the byte code for HT (0x09) was replicated to fill the all 8 bytes to avoid a potential miscompare.
3.3.11 Fixed-Point Trap Instructions

The Trap instructions are provided to test for a specified set of conditions. If any of the conditions tested by a Trap instruction are met, the system trap handler is invoked. If none of the tested conditions are met, instruction execution continues normally.

The contents of register RA are compared with either the sign-extended value of the SI field or the contents of register RB, depending on the Trap instruction. For *tdi* and *td*, the entire contents of RA (and RB) participate in the comparison; for *twi* and *tw*, only the contents of the low-order 32 bits of RA (and RB) participate in the comparison.

This comparison results in five conditions which are ANDed with TO. If the result is not 0 the system trap handler is invoked. These conditions are as follows.

<table>
<thead>
<tr>
<th>TO Bit</th>
<th>ANDed with Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Less Than, using signed comparison</td>
</tr>
<tr>
<td>1</td>
<td>Greater Than, using signed comparison</td>
</tr>
<tr>
<td>2</td>
<td>Equal</td>
</tr>
<tr>
<td>3</td>
<td>Less Than, using unsigned comparison</td>
</tr>
<tr>
<td>4</td>
<td>Greater Than, using unsigned comparison</td>
</tr>
</tbody>
</table>

Extended mnemonics for traps

A set of extended mnemonics is provided so that traps can be coded with the condition as part of the mnemonic rather than as a numeric operand. Some of these are shown as examples with the Trap instructions. See Appendix C for additional extended mnemonics.
**Trap Word Immediate D-form**

```
twi TO,RA,SI  

<table>
<thead>
<tr>
<th>3</th>
<th>TO</th>
<th>RA</th>
<th>SI</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
</tr>
<tr>
<td>31</td>
<td>21</td>
<td>16</td>
<td>8</td>
</tr>
</tbody>
</table>
```

*a ← EXTS((RA)32:63)*

- if (a < EXTS(SI)) & TO0 then TRAP
- if (a > EXTS(SI)) & TO1 then TRAP
- if (a = EXTS(SI)) & TO2 then TRAP
- if (a < EXT(SI)) & TO3 then TRAP
- if (a > EXT(SI)) & TO4 then TRAP

The contents of RA32:63 are compared with the sign-extended value of the SI field. If any bit in the TO field is set to 1 and its corresponding condition is met by the result of the comparison, the system trap handler is invoked.

If the trap conditions are met, this instruction is context synchronizing (see Book III).

**Special Registers Altered:**
- None

**Extended Mnemonics:**

Examples of extended mnemonics for Trap Word Immediate:

- **Extended mnemonic:** `twi Rx, value`
  - **Equivalent to:** `tw 8, Rx, value`

- **Extended mnemonic:** `twlei Rx, value`
  - **Equivalent to:** `tw 6, Rx, value`

**Trap Word X-form**

```
tw TO,RA,RB  

<table>
<thead>
<tr>
<th>31</th>
<th>TO</th>
<th>RA</th>
<th>RB</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
<tr>
<td>31</td>
<td>21</td>
<td>16</td>
<td>8</td>
<td>1</td>
</tr>
</tbody>
</table>
```

*a ← EXTS((RA)32:63)*

*b ← EXTS((RB)32:63)*

- if (a < b) & TO0 then TRAP
- if (a > b) & TO1 then TRAP
- if (a = b) & TO2 then TRAP
- if (a < u b) & TO3 then TRAP
- if (a > u b) & TO4 then TRAP

The contents of RA32:63 are compared with the contents of RB32:63. If any bit in the TO field is set to 1 and its corresponding condition is met by the result of the comparison, the system trap handler is invoked.

If the trap conditions are met, this instruction is context synchronizing (see Book III).

**Special Registers Altered:**
- None

**Extended Mnemonics:**

Examples of extended mnemonics for Trap Word:

- **Extended mnemonic:** `tweq Rx, Ry`
  - **Equivalent to:** `tw 4, Rx, Ry`

- **Extended mnemonic:** `twge Rx, Ry`
  - **Equivalent to:** `tw 5, Rx, Ry`

- **Extended mnemonic:** `trap`
  - **Equivalent to:** `tw 31, 0, 0`
### 3.3.11.1 64-bit Fixed-Point Trap Instructions

#### Trap Doubleword Immediate D-form

\[
\begin{array}{|c|c|c|c|c|}
\hline
& TO & RA & SI & \\hline
0 & 2 & 6 & 11 & 16 & 31 \\hline
\end{array}
\]

\[
\begin{align*}
a & \leftarrow (RA) \\
b & \leftarrow \text{EXTS}(SI) \\
\text{if} \ (a < b) \ & \text{&} \ \text{TO}_0 \ \text{then} \ \text{TRAP} \\
\text{if} \ (a > b) \ & \text{&} \ \text{TO}_1 \ \text{then} \ \text{TRAP} \\
\text{if} \ (a = b) \ & \text{&} \ \text{TO}_2 \ \text{then} \ \text{TRAP} \\
\text{if} \ (a <^u b) \ & \text{&} \ \text{TO}_3 \ \text{then} \ \text{TRAP} \\
\text{if} \ (a >^u b) \ & \text{&} \ \text{TO}_4 \ \text{then} \ \text{TRAP} \\
\end{align*}
\]

The contents of register RA are compared with the sign-extended value of the SI field. If any bit in the TO field is set to 1 and its corresponding condition is met by the result of the comparison, the system trap handler is invoked.

If the trap conditions are met, this instruction is context synchronizing (see Book III).

**Special Registers Altered:**
None

**Extended Mnemonics:**
Examples of extended mnemonics for Trap Doubleword Immediate:

\[
\begin{align*}
\text{tdi} & \text{lti} \ \text{Ra,value} & \text{tdi} & \text{16,Ra,value} \\
\text{tdi} & \text{nei} \ \text{Ra,value} & \text{tdi} & \text{24,Ra,value} \\
\end{align*}
\]

#### Trap Doubleword X-form

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
& TO & RA & RB & 68 & \\hline
0 & 31 & 6 & 11 & 16 & 21 & 26 & 31 \\hline
\end{array}
\]

\[
\begin{align*}
a & \leftarrow (RA) \\
b & \leftarrow (RB) \\
\text{if} \ (a < b) \ & \text{&} \ \text{TO}_0 \ \text{then} \ \text{TRAP} \\
\text{if} \ (a > b) \ & \text{&} \ \text{TO}_1 \ \text{then} \ \text{TRAP} \\
\text{if} \ (a = b) \ & \text{&} \ \text{TO}_2 \ \text{then} \ \text{TRAP} \\
\text{if} \ (a <^u b) \ & \text{&} \ \text{TO}_3 \ \text{then} \ \text{TRAP} \\
\text{if} \ (a >^u b) \ & \text{&} \ \text{TO}_4 \ \text{then} \ \text{TRAP} \\
\end{align*}
\]

The contents of register RA are compared with the contents of register RB. If any bit in the TO field is set to 1 and its corresponding condition is met by the result of the comparison, the system trap handler is invoked.

If the trap conditions are met, this instruction is context synchronizing (see Book III).

**Special Registers Altered:**
None

**Extended Mnemonics:**
Examples of extended mnemonics for Trap Doubleword:

\[
\begin{align*}
\text{Extended mnemonic:} & \quad \text{Equivalent to:} \\
\text{td} & \text{ge} \ Rx,Ry & \text{td} & \text{12,Rx,Ry} \\
\text{td} & \text{lnl} \ Rx,Ry & \text{td} & \text{5,Rx,Ry} \\
\end{align*}
\]

### 3.3.12 Fixed-Point Select

#### Integer Select A-form

\[
\begin{array}{|c|c|c|c|c|}
\hline
& RT & RA & RB & BC & 15 & \\hline
0 & 31 & 6 & 11 & 16 & 21 & 26 \\hline
\end{array}
\]

\[
\begin{align*}
\text{if} \ RA = 0 \ & \text{then} \ a \leftarrow 0 \ \text{else} \ a \leftarrow (RA) \\
\text{if} \ \text{CH} & \text{BC+32} \ & \text{then} \\
\ & \text{RT} \leftarrow a \\
\text{else} \\
\ & \text{RT} \leftarrow (RB) \\
\end{align*}
\]

If the contents of bit BC+32 of the Condition Register are equal to 1, then the contents of register RA (or 0) are placed into register RT. Otherwise, the contents of register RB are placed into register RT.

**Special Registers Altered:**
None

**Extended Mnemonics:**
Examples of extended mnemonics for Integer Select:

\[
\begin{align*}
\text{Extended mnemonic:} & \quad \text{Equivalent to:} \\
\text{isel} & \text{lt} \ Rx,Ry,Rz & \text{isel} & \text{Rx,Ry,Rz,0} \\
\text{isel} & \text{gt} \ Rx,Ry,Rz & \text{isel} & \text{Rx,Ry,Rz,1} \\
\text{isel} & \text{eq} \ Rx,Ry,Rz & \text{isel} & \text{Rx,Ry,Rz,2} \\
\end{align*}
\]
3.3.13 Fixed-Point Logical Instructions

The *Logical* instructions perform bit-parallel operations on 64-bit operands.

The X-form Logical instructions with $Rc=1$, and the D-form *Logical* instructions *andi.* and *andis.*, set the first three bits of CR Field 0 as described in Section 3.3.8, “Other Fixed-Point Instructions” on page 74. The Logical instructions do not change the $S0$, $OV$, $OV32$, $CA$, and $CA32$ bits in the XER.

**Extended mnemonics for logical operations**

Extended mnemonics are provided that generate two different types of "no-ops" (instructions that do nothing). The first type is the preferred form, which is optimized to minimize its use of the processor's execution resources. This form is based on the *OR Immediate* instruction. The second type is the executed form, which is intended to consume the same amount of the processor's execution resources as if it were not a no-op. This form is based on the *XOR Immediate* instruction. (There are also no-ops that have other uses, such as affecting program priority, for which extended mnemonics have not been defined.)

Extended mnemonics are provided that use the *OR* and *NOR* instructions to copy the contents of one register to another, with and without complementing. These are shown as examples with the two instructions.

See Appendix C, “Assembler Extended Mnemonics” on page 1011 for additional extended mnemonics.

---

**Programming Note**

Warning: Some forms of no-op may have side effects such as affecting program priority. Programmers should use the preferred no-op unless the side effects of some other form of no-op are intended.

---

**AND Immediate D-form**

\[
\text{andi. } RA,RS,UI
\]

\[
\begin{array}{cccccc}
28 & RS & RA & UI & & 31 \\
\hline
0 & 6 & 11 & 16 & & 31 \\
\end{array}
\]

\[RA \leftarrow (RS) \& (480 || UI)\]

The contents of register \(RS\) are ANDed with \(480 || UI\) and the result is placed into register \(RA\).

**Special Registers Altered:**

\(CR0\)

**AND Immediate Shifted D-form**

\[
\text{andis. } RA,RS,UI
\]

\[
\begin{array}{cccccc}
29 & RS & RA & UI & & 31 \\
\hline
0 & 6 & 11 & 16 & & 31 \\
\end{array}
\]

\[RA \leftarrow (RS) \& (320 || UI || 160)\]

The contents of register \(RS\) are ANDed with \(320 || UI || 160\) and the result is placed into register \(RA\).

**Special Registers Altered:**

\(CR0\)

**OR Immediate D-form**

\[
\text{ori } RA,RS,UI
\]

\[
\begin{array}{cccccc}
24 & RS & RA & UI & & 31 \\
\hline
0 & 6 & 11 & 16 & & 31 \\
\end{array}
\]

\[RA \leftarrow (RS) \| (480 || UI)\]

The contents of register \(RS\) are ORed with \(480 || UI\) and the result is placed into register \(RA\).

The preferred "no-op" (an instruction that does nothing) is:

\[\text{ori } 0,0,0\]

Some other forms of \(ori Rx,Rx,0\) provide special functions; see <xref to Book III Section 4.4.2+>.

**Special Registers Altered:**

None

**Extended Mnemonics:**

Example of extended mnemonics for *OR Immediate*:

Extended mnemonic: \(\text{ori } 0,0,0\)

Equivalent to: \(\text{nop}\)
**OR Immediate Shifted D-form**

```
<table>
<thead>
<tr>
<th>25</th>
<th>RS</th>
<th>RA</th>
<th>UI</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
</tr>
</tbody>
</table>
```

```
RA ← (RS) | | 320 | | UI | | 160 |
```

The contents of register RS are ORed with 320 | | UI | | 160 and the result is placed into register RA.

**Special Registers Altered:**
None

**XOR Immediate D-form**

```
<table>
<thead>
<tr>
<th>26</th>
<th>RS</th>
<th>RA</th>
<th>UI</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
</tr>
</tbody>
</table>
```

```
RA ← (RS) XOR (480 | | UI)
```

The contents of register RS are XORed with 480 | | UI and the result is placed into register RA.

The executed form of a "no-op" (an instruction that does nothing, but consumes execution resources nevertheless) is:

```
xori 0,0,0
```

**Special Registers Altered:**
None

**Extended Mnemonics:**

Example of extended mnemonics for XOR Immediate:

```
<table>
<thead>
<tr>
<th>Extended mnemonic</th>
<th>Equivalent to</th>
</tr>
</thead>
<tbody>
<tr>
<td>xnor</td>
<td>xori 0,0,0</td>
</tr>
</tbody>
</table>
```

**Programming Note**

The executed form of no-op should be used only when the intent is to alter the timing of a program.

**OR Immediate Shifted D-form**

```
<table>
<thead>
<tr>
<th>27</th>
<th>RS</th>
<th>RA</th>
<th>UI</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
</tr>
</tbody>
</table>
```

```
RA ← (RS) XOR | | 320 | | UI | | 160 |
```

The contents of register RS are XORed with 320 | | UI | | 160 and the result is placed into register RA.

**Special Registers Altered:**
None

**AND X-form**

```
and   RA,RS,RB (Rc=0)
and.  RA,RS,RB (Rc=1)
```

```
<table>
<thead>
<tr>
<th>31</th>
<th>RS</th>
<th>RA</th>
<th>RB</th>
<th>28</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>
```

```
RA ← (RS) & (RB)
```

The contents of register RS are ANDed with the contents of register RB and the result is placed into register RA.

**Special Registers Altered:**
None

**XOR X-form**

```
xor   RA,RS,RB (Rc=0)
xor.  RA,RS,RB (Rc=1)
```

```
<table>
<thead>
<tr>
<th>31</th>
<th>RS</th>
<th>RA</th>
<th>RB</th>
<th>316</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>
```

```
RA ← (RS) ⊕ (RB)
```

The contents of register RS are XORed with the contents of register RB and the result is placed into register RA.

**Special Registers Altered:**
None

**NAND X-form**

```
nand  RA,RS,RB (Rc=0)
nand. RA,RS,RB (Rc=1)
```

```
<table>
<thead>
<tr>
<th>31</th>
<th>RS</th>
<th>RA</th>
<th>RB</th>
<th>476</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>
```

```
RA ← ¬((RS) & (RB))
```

The contents of register RS are ANDed with the contents of register RB and the complemented result is placed into register RA.

**Special Registers Altered:**
CR0 (if Rc=1)

**Programming Note**

nand or nor with RS=RB can be used to obtain the one’s complement.
**OR X-form**

Or

\[
\text{or. } \text{RA,RS,RB} \quad \text{(Rc=0)}
\]

Or.

\[
\text{or. } \text{RA,RS,RB} \quad \text{(Rc=1)}
\]

\[
\begin{array}{cccccc}
31 & RS & RA & RB & 444 & R6 \\
0 & 6 & 11 & 16 & 21 & 31 \\
\end{array}
\]

\[RA \leftarrow (RS) \mid (RB)\]

The contents of register RS are ORed with the contents of register RB and the result is placed into register RA.

Some forms of or Rx,Rx,Rx provide special functions; see Section 3.2 and Section 4.3.3, both in Book II.

**Special Registers Altered:**

CRO

(if Rc=1)

**Extended Mnemonics:**

Example of extended mnemonics for OR:

Extended mnemonic:  
Equivalent to:

\[
m_r \quad Rx, Ry \quad \text{or} \quad Rx, Ry, Ry
\]

**OR with Complement X-form**

orc

\[
\text{orc. } \text{RA,RS,RB} \quad \text{(Rc=0)}
\]

orc.

\[
\text{orc. } \text{RA,RS,RB} \quad \text{(Rc=1)}
\]

\[
\begin{array}{cccccc}
31 & RS & RA & RB & 412 & R6 \\
0 & 6 & 11 & 16 & 21 & 31 \\
\end{array}
\]

\[RA \leftarrow (RS) \mid \neg(RB)\]

The contents of register RS are ORed with the complement of the contents of register RB and the result is placed into register RA.

**Special Registers Altered:**

CRO

(if Rc=1)

**NOR X-form**

nor

\[
\text{nor. } \text{RA,RS,RB} \quad \text{(Rc=0)}
\]

nor.

\[
\text{nor. } \text{RA,RS,RB} \quad \text{(Rc=1)}
\]

\[
\begin{array}{cccccc}
31 & RS & RA & RB & 124 & R6 \\
1 & 6 & 11 & 16 & 21 & 31 \\
\end{array}
\]

\[RA \leftarrow \neg((RS) \mid (RB))\]

The contents of register RS are ORed with the contents of register RB and the complemented result is placed into register RA.

**Special Registers Altered:**

CRO

(if Rc=1)

**Equivalent X-form**

eqv

\[
\text{eqv. } \text{RA,RS,RB} \quad \text{(Rc=0)}
\]

eqv.

\[
\text{eqv. } \text{RA,RS,RB} \quad \text{(Rc=1)}
\]

\[
\begin{array}{cccccc}
31 & RS & RA & RB & 284 & R6 \\
0 & 6 & 11 & 16 & 21 & 31 \\
\end{array}
\]

\[RA \leftarrow (RS) \equiv (RB)\]

The contents of register RS are XORed with the contents of register RB and the complemented result is placed into register RA.

**Special Registers Altered:**

CRO

(if Rc=1)

**AND with Complement X-form**

andc

\[
\text{andc. } \text{RA,RS,RB} \quad \text{(Rc=0)}
\]

andc.

\[
\text{andc. } \text{RA,RS,RB} \quad \text{(Rc=1)}
\]

\[
\begin{array}{cccccc}
31 & RS & RA & RB & 60 & R6 \\
0 & 6 & 11 & 16 & 21 & 31 \\
\end{array}
\]

\[RA \leftarrow (RS) \& \neg(RB)\]

The contents of register RS are ANDed with the complement of the contents of register RB and the result is placed into register RA.

**Special Registers Altered:**

CRO

(if Rc=1)
### Extend Sign Byte X-form

**extsb**
```
RA,RS  (Rc=0)
```

**extsb.**
```
RA,RS  (Rc=1)
```

1. \( s \leftarrow (RS)_{56} \)
2. \( RA_{56:63} \leftarrow (RS)_{56:63} \)
3. \( RA_{0:55} \leftarrow s_{56} \)

\( (RS)_{56:63} \) are placed into \( RA_{56:63} \), \( RA_{0:55} \) are filled with a copy of \( (RS)_{56} \).

**Special Registers Altered:**

- \( CR0 \) (if \( Rc=1 \))

### Extend Sign Halfword X-form

**extsh**
```
RA,RS  (Rc=0)
```

**extsh.**
```
RA,RS  (Rc=1)
```

1. \( s \leftarrow (RS)_{48} \)
2. \( RA_{48:63} \leftarrow (RS)_{48:63} \)
3. \( RA_{0:47} \leftarrow s_{48} \)

\( (RS)_{48:63} \) are placed into \( RA_{48:63} \), \( RA_{0:47} \) are filled with a copy of \( (RS)_{48} \).

**Special Registers Altered:**

- \( CR0 \) (if \( Rc=1 \))

### Compare Bytes X-form

**cmpb**
```
RA,RS,RB
```

```text
do n = 0 to 7
  if \( RS_{8 \times n:8 \times (n+7)} = (RB)_{8 \times n:8 \times (n+7)} \) then
    RA_{8 \times n:8 \times (n+7)} \leftarrow 0xFF
  else
    RA_{8 \times n:8 \times (n+7)} \leftarrow 0x00
```

Each byte of the contents of register \( RS \) is compared to each corresponding byte of the contents in register \( RB \). If they are equal, the corresponding byte in \( RA \) is set to \( 0xFF \). Otherwise the corresponding byte in \( RA \) is set to \( 0x00 \).

**Special Registers Altered:**

- None

---

### Count Leading Zeros Word X-form

**cntlzwr**
```
RA,RS  (Rc=0)
```

**cntlzwr.**
```
RA,RS  (Rc=1)
```

1. \( n \leftarrow 32 \)
2. **do while** \( n < 64 \)
   - **if** \( (RS)_{63-n} = 0b1 \) then leave
   - \( n \leftarrow n + 1 \)
3. \( RA \leftarrow n - 32 \)

A count of the number of consecutive zero bits starting at bit 32 of register \( RS \) is placed into register \( RA \). This number ranges from 0 to 32, inclusive.

**Special Registers Altered:**

- \( CR0 \) (if \( Rc=1 \))

---

### Programming Note

For both **Count Leading Zeros** instructions, if \( Rc=1 \) then \( LT \) is set to 0 in CR Field 0.

---

### Count Trailing Zeros Word X-form

**cnttzw**
```
RA,RS  (Rc=0)
```

**cnttzw.**
```
RA,RS  (Rc=1)
```

1. \( n \leftarrow 0 \)
2. **do while** \( n < 32 \)
   - **if** \( (RS)_{64-n} = 0b01 \) then leave
   - \( n \leftarrow n + 1 \)
3. \( RA \leftarrow EXTZ64(n) \)

A count of the number of consecutive zero bits starting at bit 63 of the rightmost word of register \( RS \) is placed into register \( RA \). This number ranges from 0 to 32, inclusive.

**Special Registers Altered:**

- \( CR0 \) (if \( Rc=1 \))

---

102 Power ISA™ I
**Population Count Bytes X-form**

\[ \text{popcntb} \quad \text{RA, RS} \]

\[
\begin{array}{cccccc}
31 & RS & RA & /// & 122 & Rb \\
0 & 6 & 11 & 16 & 21 & 31
\end{array}
\]

\[
\begin{align*}
\text{do } i &= 0 \text{ to } 7 \\
& \quad n \leftarrow 0 \\
\text{do } j &= 0 \text{ to } 7 \\
& \quad \text{if } (RS)(i \times 8)+j = 1 \text{ then} \\
& \quad n \leftarrow n+1 \\
RA(i \times 8):(i \times 8)+7 & \leftarrow n
\end{align*}
\]

A count of the number of one bits in each byte of register \( RS \) is placed into the corresponding byte of register \( RA \). This number ranges from 0 to 8, inclusive.

**Special Registers Altered:**

None

**Population Count Words X-form**

\[ \text{popcntw} \quad \text{RA, RS} \]

\[
\begin{array}{cccccc}
31 & RS & RA & /// & 378 & / \\
0 & 6 & 11 & 16 & 21 & 31
\end{array}
\]

\[
\begin{align*}
\text{do } i &= 0 \text{ to } 1 \\
& \quad n \leftarrow 0 \\
\text{do } j &= 0 \text{ to } 31 \\
& \quad \text{if } (RS)(i \times 32)+j = 1 \text{ then} \\
& \quad n \leftarrow n+1 \\
RA(i \times 32):(i \times 32)+31 & \leftarrow n
\end{align*}
\]

A count of the number of one bits in each word of register \( RS \) is placed into the corresponding word of register \( RA \). This number ranges from 0 to 32, inclusive.

**Special Registers Altered:**

None

**Parity Word X-form**

\[ \text{prtyw} \quad \text{RA, RS} \]

\[
\begin{array}{cccccc}
31 & RS & RA & /// & 154 & / \\
0 & 6 & 11 & 16 & 21 & 31
\end{array}
\]

\[
\begin{align*}
s & \leftarrow 0 \\
t & \leftarrow 0 \\
\text{do } i &= 0 \text{ to } 3 \\
& \quad s \leftarrow s \oplus (RS)(i \times 8)+7 \\
& \quad t \leftarrow t \oplus (RS)(i \times 8)+7 \\
RA0:31 & \leftarrow 320 || s \\
RA32:63 & \leftarrow 320 || t
\end{align*}
\]

The least significant bit in each byte of \( (RS)0:31 \) is examined. If there is an odd number of one bits the value 1 is placed into \( RA0:31 \); otherwise the value 0 is placed into \( RA0:31 \). The least significant bit in each byte of \( (RS)32:63 \) is examined. If there is an odd number of one bits the value 1 is placed into \( RA32:63 \); otherwise the value 0 is placed into \( RA32:63 \).

**Special Registers Altered:**

None

**Programming Note**

The **Parity** instructions are designed to be used in conjunction with the **Population Count** instruction to compute the parity of words or a doubleword. The parity of the upper and lower words in \( (RS) \) can be computed as follows.

\[ \text{popcntb} \quad \text{RA, RS} \]
\[ \text{prtyw} \quad \text{RA, RA} \]

The parity of \( (RS) \) can be computed as follows.

\[ \text{popcntb} \quad \text{RA, RS} \]
\[ \text{prtyd} \quad \text{RA, RA} \]
3.3.13.1 64-bit Fixed-Point Logical Instructions

**Extend Sign Word X-form**

\[

\quad n & \leftarrow n + 1 \\
\quad RA & \leftarrow \text{EXTZ64}(n)
\end{align*}
\]

A count of the number of consecutive zero bits starting at bit 63 of register \(RS\) is placed into register \(RA\). This number ranges from 0 to 64, inclusive.

If \(Rc\) is equal to 1, CR Field 0 is set to reflect the result.

**Special Registers Altered:**

None
Count Leading Zeros Doubleword under bit Mask X-form

```plaintext
cntzdm  RA,RS,RB
      31  RS  RA  RB  59 / 31 6 11 16 21
```

count = 0
do i = 0 to 63
  if((RB)i=1) then do
    if((RS)i=1) then break
    count ← count + 1
  end
end
RA ← EXTZ64(count)

Let \( n \) be the number of bits in register RB having the value 1.

Extract and pack together the contents of the bits in register RS corresponding to a mask specified in register RB, creating an \( n \)-bit value.

Count the number of contiguous leftmost 0 bits in the \( n \)-bit extracted value and place the result into register RA.

Special Registers Altered:
None

Count Trailing Zeros Doubleword under bit Mask X-form

```plaintext
cntzdm  RA,RS,RB
      31  RS  RA  RB  571 / 31 6 11 16 21
```

count = 0
do i = 0 to 63
  if((RB)63-i=1) then do
    if((RS)63-i=1) then break
    count ← count + 1
  end
end
RA ← EXTZ64(count)

Let \( n \) be the number of bits in register RB having the value 1.

Extract and pack together the contents of bits in register RS corresponding to a mask specified in register RB, creating an \( n \)-bit value.

Count the number of contiguous rightmost 0 bits in the \( n \)-bit extracted value and place the result into register RA.

Special Registers Altered:
None

Bit Permute Doubleword X-form

```plaintext
bpermd  RA,RS,RB
      31  RS  RA  RB  252 / 31 6 11 16 21
```

Eight permuted bits are produced. For each permuted bit \( i \) where \( i \) ranges from 0 to 7 and for each byte \( i \) of RS, do the following.

If byte \( i \) of RS is less than 64, permuted bit \( i \) is set to the bit of RB specified by byte \( i \) of RS; otherwise permuted bit \( i \) is set to 0.

The permuted bits are placed in the least-significant byte of RA, and the remaining bits are filled with 0s.

Special Registers Altered:
None

Programming Note

The fact that the permuted bit is 0 if the corresponding index value exceeds 63 permits the permuted bits to be selected from a 128-bit quantity, using a single index register. For example, assume that the 128-bit quantity \( Q \), from which the permuted bits are to be selected, is in registers r2 (high-order 64 bits of \( Q \)) and r3 (low-order 64 bits of \( Q \)), that the index values are in register r1, with each byte of r1 containing a value in the range 0:127, and that each byte of register r4 contains the value 64. The following code sequence selects eight permuted bits from \( Q \) and places them into the low-order byte of r6.

```plaintext
bpermd  r6,r1,r2 # select from high-order half of Q
xor  r0,r1,r4 # adjust index values
bpermd  r5,r0,r3 # select from low-order half of Q
or  r6,r6,r5 # merge the two selections
```
**Centrifuge Doubleword X-form**

```plaintext
cfuged RA,RS,RB
```

```plaintext
ptr0 ← 0
ptr1 ← 0
do i = 0 to 63
  if((RB)i==0) then do
    resultptr0 ← (RS)i
    ptr0 ← ptr0 + 1
  end
  if((RB)63-i==1) then do
    result63-ptr1 ← (RS)63-i
    ptr1 ← ptr1 + 1
  end
end
RA ← result
```

The bits in GPR[RS] whose corresponding bits in the mask in GPR[RB] equal 1 are placed in the rightmost bits in GPR[RA] maintaining their relative original order. The other bits in GPR[RS] are placed in the leftmost bits in GPR[RA] maintaining their relative original order.

**Special Registers Altered:**
None

**Parallel Bits Extract Doubleword X-form**

```plaintext
pextd RA,RS,RB
```

```plaintext
result ← 0
mask ← (RB)
m ← 0
k ← 0
do while(m < 64)
  if((RB)63-m == 1) then do
    result63-m ← (RS)63-m
    k ← k + 1
  end
  m ← m + 1
end
RA ← result
```

Let mask be the contents of register RB.

The contents of the bits in register RS corresponding to bits in mask containing a 1 are packed into an n-bit value. The extracted value is placed into register RA.

**Special Registers Altered:**
None

---

**Parallel Bits Deposit Doubleword X-form**

```plaintext
pdepd RA,RS,RB
```

```plaintext
result ← 0
mask ← (RB)
m ← 0
k ← 0
do while(m < 64)
  if((RB)63-m == 1) then do
    result63-m ← (RS)63-m
    k ← k + 1
  end
  m ← m + 1
end
RA ← result
```

Let mask be the contents of register RB.

Let n be the number of bits in mask having the value 1.

The contents of the rightmost n bits of register RS are placed into register RA under control of mask as follows.

- The contents of bit 63 of register RS are placed into the bit in register RA corresponding to the rightmost bit in mask that contains a 1,
- The contents of bit 62 of register RS are placed into the bit in register RA corresponding to the second rightmost bit in mask that contains a 1, and so forth until
- The contents of bit 64-n of register RS are placed into the bit in register RA corresponding to the leftmost bit in mask that contains a 1.

The contents of bits in register RA corresponding to bits in mask that contain a 0 are set to 0.

**Special Registers Altered:**
None
3.3.14 Fixed-Point Rotate and Shift Instructions

The Fixed-Point Facility performs rotation operations on data from a GPR and returns the result, or a portion of the result, to a GPR.

The rotation operations rotate a 64-bit quantity left by a specified number of bit positions. Bits that exit from position 0 enter at position 63.

Two types of rotation operation are supported.

For the first type, denoted rotatem64 or ROTL64, the value rotated is the given 64-bit value. The rotatem64 operation is used to rotate a given 64-bit quantity.

For the second type, denoted rotatem32 or ROTL32, the value rotated consists of two copies of bits 32:63 of the given 64-bit value, one copy in bits 0:31 and the other in bits 32:63. The rotatem32 operation is used to rotate a given 32-bit quantity.

The Rotate and Shift instructions employ a mask generator. The mask is 64 bits long, and consists of 1-bits from a start bit, mstart, through and including a stop bit, mstop, and 0-bits elsewhere. The values of mstart and mstop range from 0 to 63. If mstart > mstop, the 1-bits wrap around from position 63 to position 0. Thus the mask is formed as follows:

```plaintext
if mstart ≤ mstop then
  maskmstart:mstop = ones
  maskall other bits = zeros
else
  maskmstart:63 = ones
  mask0:mstop = ones
  maskall other bits = zeros
```

There is no way to specify an all-zero mask.

For instructions that use the rotatem32 operation, the mask start and stop positions are always in the low-order 32 bits of the mask.

The use of the mask is described in following sections.

The Rotate and Shift instructions with Rc=1 set the first three bits of CR field 0 as described in Section 3.3.8, “Other Fixed-Point Instructions” on page 74. Rotate and Shift instructions do not change the OV, OV32, and SO bits. Rotate and Shift instructions, except algebraic right shifts, do not change the CA and CA32 bits.

Extended mnemonics for rotates and shifts

The Rotate and Shift instructions, while powerful, can be complicated to code (they have up to five operands). A set of extended mnemonics is provided that allow simpler coding of often-used functions such as clearing the leftmost or rightmost bits of a register, left justifying or right justifying an arbitrary field, and performing simple rotates and shifts. Some of these are shown as examples with the Rotate instructions. See Appendix C, “Assembler Extended Mnemonics” on page 1011 for additional extended mnemonics.

### 3.3.14.1 Fixed-Point Rotate Instructions

These instructions rotate the contents of a register. The result of the rotation is

- inserted into the target register under control of a mask (if a mask bit is 1 the associated bit of the rotated data is placed into the target register, and if the mask bit is 0 the associated bit in the target register remains unchanged); or
- ANDed with a mask before being placed into the target register.

The Rotate Left instructions allow right-rotation of the contents of a register to be performed (in concept) by a left-rotation of 64 - n, where n is the number of bits by which to rotate right. They allow right-rotation of the contents of the low-order 32 bits of a register to be performed (in concept) by a left-rotation of 32 - n, where n is the number of bits by which to rotate right.

<table>
<thead>
<tr>
<th>Rotate Left Word Immediate then AND with Mask M-form</th>
</tr>
</thead>
<tbody>
<tr>
<td>nlwimm</td>
</tr>
<tr>
<td>nlwimm.</td>
</tr>
<tr>
<td>21</td>
</tr>
<tr>
<td>0</td>

<tr>
<td>r ← ROTL32(RS),m32, n)</td>
</tr>
<tr>
<td>m ← MASK(MB+32, ME+32)</td>
</tr>
<tr>
<td>RA ← r &amp; m</td>
</tr>
</tbody>
</table>

The contents of register RS are rotated32 left SH bits. A mask is generated having 1-bits from bit MB+32 through bit ME+32 and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register RA.

Special Registers Altered:

- CR0 (if Rc=1)
Extended Mnemonics:

Examples of extended mnemonics for Rotate Left Word Immediate then AND with Mask:

<table>
<thead>
<tr>
<th>Extended mnemonic:</th>
<th>Equivalent to:</th>
</tr>
</thead>
<tbody>
<tr>
<td>extl/w Rx,Ry,n,b</td>
<td>rlwnm Rx,Ry,b,0,n-1</td>
</tr>
<tr>
<td>srwi Rx,Ry,n</td>
<td>rlwnm Rx,Ry,32-n,n,31</td>
</tr>
<tr>
<td>clrrw Rx,Ry,n</td>
<td>rlwnm Rx,Ry,0,0,31-n</td>
</tr>
</tbody>
</table>

Programming Note

Let RSL represent the low-order 32 bits of register RS, with the bits numbered from 0 through 31.

*rlwinm* can be used to extract an n-bit field that starts at bit position b in RSL, right-justified into the low-order 32 bits of register RA (clearing the remaining 32-n bits of the low-order 32 bits of RA), by setting SH=b+n, MB=32-n, and ME=n-1. It can be used to extract an n-bit field that starts at bit position b in RSL, left-justified into the low-order 32 bits of register RA (clearing the remaining 32-n bits of the low-order 32 bits of RA), by setting SH=b, MB=0, and ME=n-1. It can be used to rotate the contents of the low-order 32 bits of a register left (right) by n bits, by setting SH=n (32-n), MB=0, and ME=31. It can be used to shift the contents of the low-order 32 bits of a register right by n bits, by setting SH=32-n, MB=n, and ME=31. It can be used to clear the high-order b bits of the low-order 32 bits of a register and then shift the result left by n bits, by setting SH=n, MB=b-n, and ME=31-n. It can be used to clear the low-order n bits of the low-order 32 bits of a register, by setting SH=0, MB=0, and ME=31-n.

For all the uses given above, the high-order 32 bits of register RA are cleared.

Extended mnemonics are provided for some of these uses; see Appendix C, “Assembler Extended Mnemonics” on page 1011.

**Rotate Left Word Immediate then Mask Insert M-form**

\[
\text{rlwinm} \quad (Rc=0) \\
\text{rlwinm} \quad (Rc=1)
\]

```
crlslidl Rx,Ry,b,n rldc Rx,Ry,n,b-n
```

**Programming Note**

`rldic` can be used to clear the high-order $b$ bits of the contents of a register and then shift the result left by $n$ bits, by setting $SH=n$ and $MB=b \cdot n$. It can be used to clear the high-order $n$ bits of a register, by setting $SH=0$ and $MB=n$.

Extended mnemonics are provided for both of these uses (the second devolves to `rldicl`); see Appendix C, “Assembler Extended Mnemonics” on page 1011.

**Rotate Left Doubleword then Clear Left**

**MDS-form**

```
   rldcl RA,RS,RB,MB (Rc=0)
   rldcl. RA,RS,RB,MB (Rc=1)
```

<table>
<thead>
<tr>
<th>30</th>
<th>31</th>
<th>30</th>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td>RS</td>
<td>RA</td>
<td>RB</td>
<td>mb</td>
</tr>
<tr>
<td>6</td>
<td>16</td>
<td>21</td>
<td>27</td>
</tr>
<tr>
<td>0</td>
<td>32</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```
n ← (RB)_{58:63}
r ← NOTL64(RS), n
b ← mb5 || mb0:4
m ← MASK(b, 63)
RA ← r & m
```

The contents of register $RS$ are rotated left the number of bits specified by $(RB)_{58:63}$. A mask is generated having 1-bits from bit $MB$ through bit 63 and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register $RA$.

**Special Registers Altered:**

$CR0$ (if $Rc=1$)

**Extended Mnemonics:**

Example of extended mnemonics for *Rotate Left Doubleword then Clear Left:*

```
rcpld Rx,Ry,Rz rldcl Rx,Ry,Rz,0
```

**Programming Note**

`rldcl` can be used to extract an $n$-bit field that starts at variable bit position $b$ in register $RS$, right-justified into register $RA$ (clearing the remaining $64-n$ bits of $RA$), by setting $RB_{58:63}=b+n$ and $MB=64-n$. It can be used to rotate the contents of a register left (right) by variable $n$ bits, by setting $RB_{58:63}=n$ ($64-n$) and $MB=0$.

Extended mnemonics are provided for some of these uses; see Appendix C, “Assembler Extended Mnemonics” on page 1011.
**Rotate Left Doubleword then Clear Right MDS-form**

\[
\begin{align*}
\text{rldcr} & \quad \text{RA,RS,RB,ME} \\
\text{rldcr} & \quad \text{RA,RS,RB,ME}
\end{align*}
\]

\[
\begin{array}{cccccc}
0 & 30 & 6 & 11 & 16 & 21 & 27 & 31 \\
\end{array}
\]

\[
\begin{array}{l}
\begin{align*}
n & \leftarrow (RB)_{58:63} \\
r & \leftarrow \text{ROTL}_{64}((RS), n) \\
e & \leftarrow \text{me}_5 || \text{me}_0:4 \\
m & \leftarrow \text{MASK}(0, e) \\
\text{RA} & \leftarrow r \& m
\end{align*}
\end{array}
\]

The contents of register \( RS \) are rotated left the number of bits specified by \( (RB)_{58:63} \). A mask is generated having 1-bits from bit \( ME \) and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register \( RA \).

**Special Registers Altered:**

- CR0 (if \( Rc=1 \))

---

**Programming Note**

**rldcr** can be used to extract an \( n \)-bit field that starts at variable bit position \( b \) in register \( RS \), left-justified into register \( RA \) (clearing the remaining \( 64-n \) bits of \( RA \)), by setting \( RB_{58:63}=b \) and \( ME=n-1 \). It can be used to rotate the contents of a register left (right) by variable \( n \) bits, by setting \( RB_{58:63}=n \) \( (64-n) \) and \( ME=63 \).

Extended mnemonics are provided for some of these uses (some devolve to **rldcl**); see Appendix C, "Assembler Extended Mnemonics" on page 1011.

---

**Rotate Left Doubleword Immediate then Mask Insert MD-form**

\[
\begin{align*}
\text{rldimi} & \quad \text{RA,RS,SH,MB} \\
\text{rldimi} & \quad \text{RA,RS,SH,MB}
\end{align*}
\]

\[
\begin{array}{cccccc}
0 & 30 & 6 & 11 & 16 & 21 & 27 & 31 \\
\end{array}
\]

\[
\begin{array}{l}
\begin{align*}
n & \leftarrow \text{sh}_5 || \text{sh}_0:4 \\
r & \leftarrow \text{ROTL}_{64}((RS), n) \\
b & \leftarrow \text{mb}_5 || \text{mb}_0:4 \\
m & \leftarrow \text{MASK}(b, \neg n) \\
\text{RA} & \leftarrow r \& m | (RA) \& \neg m
\end{align*}
\end{array}
\]

The contents of register \( RS \) are rotated left \( SH \) bits. A mask is generated having 1-bits from bit \( MB \) through bit \( 63-SH \) and 0-bits elsewhere. The rotated data are inserted into register \( RA \) under control of the generated mask.

**Special Registers Altered:**

- CR0 (if \( Rc=1 \))

---

**Extended Mnemonics:**

Example of extended mnemonics for **Rotate Left Doubleword Immediate then Mask Insert**:

- Extended mnemonic: **insrdi** \( Rx,Ry,n,b \) equivalent to: **rldimi** \( Rx,Ry,64-(b+n),b \)

---

**Programming Note**

**rldimi** can be used to insert an \( n \)-bit field that is right-justified in register \( RS \), into register \( RA \) starting at bit position \( b \), by setting \( SH=64-(b+n) \) and \( MB=b \).

An extended mnemonic is provided for this use; see Appendix C, "Assembler Extended Mnemonics" on page 1011.
3.3.14.2 Fixed-Point Shift Instructions

The instructions in this section perform left and right shifts.

Extended mnemonics for shifts

Immediate-form logical (unsigned) shift operations are obtained by specifying appropriate masks and shift values for certain Rotate instructions. A set of extended mnemonics is provided to make coding of such shifts simpler and easier to understand. Some of these are shown as examples with the Rotate instructions. See Appendix C, “Assembler Extended Mnemonics” on page 1011 for additional extended mnemonics.

Programming Note

Any Shift Right Algebraic instruction, followed by addze, can be used to divide quickly by 2^n. The setting of the CA and CA32 bits by the Shift Right Algebraic instructions is independent of mode.

**Shift Left Word X-form**

```
slw RA, RS, RB  (Rc=0)
slw. RA, RS, RB  (Rc=1)
```

<table>
<thead>
<tr>
<th>31</th>
<th>6</th>
<th>16</th>
<th>21</th>
<th>24</th>
<th>Rd</th>
</tr>
</thead>
<tbody>
<tr>

<td>11</td>
<td>16</td>
<td>21</td>
<td>Rd</td>
</tr>
</tbody>
</table>

\[
n \leftarrow (RB)_{59:63}
\]

\[
r \leftarrow \text{ROTL32}(RS)_{32:63}, n
\]

\[
\text{if } (RB)_{58} = 0 \text{ then }
\]

\[
m \leftarrow \text{MASK}(32, 63-n)
\]

\[
\text{else } m \leftarrow 64
\]

RA \leftarrow r \& m

The contents of the low-order 32 bits of register RS are shifted left the number of bits specified by (RB)_{58:63}. Bits shifted out of position 32 are lost. Zeros are supplied to the vacated positions on the right. The 32-bit result is placed into RA_{32:63}. RA_{0:31} are set to zero. Shift amounts from 32 to 63 give a zero result.

**Special Registers Altered:**

C0 (if \( \text{Rc}=1 \))

**Shift Right Word X-form**

```
srw RA, RS, RB  (Rc=0)
srw. RA, RS, RB  (Rc=1)
```

<table>

\]

\[
m \leftarrow \text{MASK}(n+32, 63)
\]

\[
\text{else } m \leftarrow 64
\]

RA \leftarrow r \& m

The contents of the low-order 32 bits of register RS are shifted right the number of bits specified by (RB)_{58:63}. Bits shifted out of position 63 are lost. Zeros are supplied to the vacated positions on the left. The 32-bit result is placed into RA_{32:63}. RA_{0:31} are set to zero. Shift amounts from 32 to 63 give a zero result.

**Special Registers Altered:**

C0 (if \( \text{Rc}=1 \))
### Shift Right Algebraic Word Immediate X-form

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>624</th>
<th>Rc</th>
</tr>
</thead>
<tbody>
<tr>
<td>srawi</td>
<td>RA, RS, SH</td>
<td>(Rc=0)</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>srawi.</td>
<td>RA, RS, SH</td>
<td>(Rc=1)</td>
<td></td>
<td></td>
<td></td>
<td></td>

 RA \leftarrow r \& m | (64 \& \neg m) \\
 \text{carry} \leftarrow s \& ((r \& \neg m)_{32:63} \neq 0) \\
 CA \leftarrow \text{carry} \\
 CA32 \leftarrow \text{carry}
\]

The contents of the low-order 32 bits of register `RS` are shifted right `SH` bits. Bits shifted out of position 63 are lost. Bit 32 of `RS` is replicated to fill the vacated positions on the left. The 32-bit result is placed into `RA_{32:63}`. Bit 32 of `RS` is replicated to fill `RA_{0:31}`. `CA` and `CA32` are set to 1 if the low-order 32 bits of `(RS)` contain a negative number and any 1-bits are shifted out of position 63; otherwise `CA` and `CA32` are set to 0. A shift amount of zero causes `RA` to receive `EXTS((RS)_{32:63})`, and `CA` and `CA32` to be set to 0.

**Special Registers Altered:**
- CA
- CA32
- CR0

(if Rc = 1)

### Shift Right Algebraic Word X-form

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>

</tr>
</tbody>
</table>

\[
n \leftarrow (RB)_{59:63} \\
r \leftarrow \text{ROTL}_{32}((RS)_{32:63}, 64-n) \\
\text{if } (RB)_{58} = 0 \text{ then } m \leftarrow \text{MASK}(n+32, 63) \\
\text{else } m \leftarrow 64 \\
 s \leftarrow (RS)_{32} \\
 RA \leftarrow r \& m | (64 \& \neg m) \\
\text{carry} \leftarrow s \& ((r \& \neg m)_{32:63} \neq 0) \\
 CA \leftarrow \text{carry} \\
 CA32 \leftarrow \text{carry}
\]

The contents of the low-order 32 bits of register `RS` are shifted right the number of bits specified by `(RB)_{59:63}`. Bits shifted out of position 63 are lost. Bit 32 of `RS` is replicated to fill the vacated positions on the left. The 32-bit result is placed into `RA_{32:63}`. Bit 32 of `RS` is replicated to fill `RA_{0:31}`. `CA` and `CA32` are set to 1 if the low-order 32 bits of `(RS)` contain a negative number and any 1-bits are shifted out of position 63; otherwise `CA` and `CA32` are set to 0. A shift amount of zero causes `RA` to receive `EXTS((RS)_{32:63})`, and `CA` and `CA32` to be set to 0. Shift amounts from 32 to 63 give a result of 64 sign bits, and cause `CA` and `CA32` to receive the sign bit of `(RS)_{32:63}`.

**Special Registers Altered:**
- CA
- CA32
- CR0

(if Rc = 1)
### 3.3.14.2.1 64-bit Fixed-Point Shift Instructions

#### Shift Left Doubleword X-form

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Source Registers</th>
<th>Destination Registers</th>
<th>Flags</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sld RA,RS,RB</td>
<td>(Rc=0)</td>
<td>RA,RS,RB</td>
<td></td>
<td>64-bit fixed-point shift instruction</td>
</tr>
<tr>
<td>sld. RA,RS,RB</td>
<td>(Rc=1)</td>
<td>RA,RS,RB</td>
<td></td>
<td>64-bit fixed-point shift instruction with sign extension</td>
</tr>
</tbody>
</table>

The contents of register `RS` are shifted left the number of bits specified by `(RB)57:63`. Bits shifted out of position 0 are lost. Zeros are supplied to the vacated positions on the right. The result is placed into register `RA`. Shift amounts from 64 to 127 give a zero result.

**Special Registers Altered:**

- `CR0` (if `Rc=1`)

#### Shift Right Algebraic Doubleword Immediate X-form

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Source Registers</th>
<th>Destination Registers</th>
<th>Flags</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sradi RA,RS,SH</td>
<td>(Rc=0)</td>
<td>RA,RS,SH</td>
<td></td>
<td>64-bit fixed-point shift instruction with immediate shift right</td>
</tr>
<tr>
<td>sradi. RA,RS,SH</td>
<td>(Rc=1)</td>
<td>RA,RS,SH</td>
<td></td>
<td>64-bit fixed-point shift instruction with immediate sign extension</td>
</tr>
</tbody>
</table>

The contents of register `RS` are shifted right the number of bits specified by `(RB)57:63`. Bits shifted out of position 63 are lost. Bit 0 of `RS` is replicated to fill the vacated positions on the left. The result is placed into register `RA`. CA and CA32 are set to 1 if any 1-bits are shifted out of position 63; otherwise CA and CA32 are set to 0. A shift amount of zero causes RA to be set equal to |RS|, and CA and CA32 to be set to 0.

**Special Registers Altered:**

- `CA`  
- `CA32`  
- `CR0` (if `Rc=1`)
### Extend Sign Word and Shift Left Immediate

**XS-form**

| extswsli RA,RS,SH | (RC = 0) |
| extswsli RA,RS,SH | (RC = 1) |

<table>
<thead>
<tr>
<th>31</th>
<th>RS</th>
<th>RA</th>
<th>sh</th>
<th>445</th>
<th>e</th>
<th>RC</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td></td>
</tr>
</tbody>
</table>

\[
\begin{align*}
\text{n} & \leftarrow s_{32} \mid s_{0:4} \\
\text{r} & \leftarrow \text{ROTL64} (\text{EXTS64}(R_{32:63}), n) \\
\text{m} & \leftarrow \text{MASK}(0, 63-n) \\
\text{RA} & \leftarrow r \& m
\end{align*}
\]

The contents of the low order 32 bits of RS are sign-extended to 64 bits and then shifted left SH bits. Bits shifted out of bit 0 are lost. Zeros are supplied to vacated bits on the right. The result is placed in register RA.

**Special Registers Altered:**

CR0 (if RC = 1)
### 3.3.15 Binary Coded Decimal (BCD) Assist Instructions

The Binary Coded Decimal Assist instructions operate on Binary Coded Decimal operands (cdtbcd and addg6s) and Decimal Floating-Point operands (cdt-bcd). See Chapter 5 for additional information.

#### Convert Declets To Binary Coded Decimal X-form

<table>
<thead>
<tr>
<th>cdtbcdc</th>
<th>RA, RS</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RS</td>
</tr>
<tr>
<td>0</td>
<td>6</td>
</tr>
</tbody>
</table>

- \( \text{do} \ i = 0 \ \text{to} \ 1 \)
- \( n \leftarrow i \times 32 \)
- \( R_{A+n+0:n+7} \leftarrow 0 \)
- \( R_{A+n+8:n+19} \leftarrow \text{DPD_TO_BCD}(R_{S+n+12:n+21}) \)
- \( R_{A+n+20:n+31} \leftarrow \text{DPD_TO_BCD}(R_{S+n+22:n+31}) \)

The low-order 20 bits of each word of register RS contain two declets which are converted to six, 4-bit BCD fields; each set of six, 4-bit BCD fields is placed into the low-order 24 bits of the corresponding word in RA. The high-order 8 bits in each word of RA are set to 0.

**Special Registers Altered:** None

#### Convert Binary Coded Decimal To Declets X-form

<table>
<thead>
<tr>
<th>cbcddc</th>
<th>RA, RS</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RS</td>
</tr>
<tr>
<td>0</td>
<td>6</td>
</tr>
</tbody>
</table>

- \( \text{do} \ i = 0 \ \text{to} \ 1 \)
- \( n \leftarrow i \times 32 \)
- \( R_{A+n+0:n+11} \leftarrow 0 \)
- \( R_{A+n+12:n+21} \leftarrow \text{BCD_TO_DPD}(R_{S+n+8:n+19}) \)
- \( R_{A+n+22:n+31} \leftarrow \text{BCD_TO_DPD}(R_{S+n+20:n+31}) \)

The low-order 24 bits of each word of register RS contain six, 4-bit BCD fields which are converted to two declets; each set of two declets is placed into the low-order 20 bits of the corresponding word in RA. The high-order 12 bits in each word of RA are set to 0.

If a 4-bit BCD field has a value greater than 9 the results are undefined.

**Special Registers Altered:** None
**Add and Generate Sixes XO-form**

```plaintext
addg6s RT,RA,RB
```

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>22</th>
<th>74</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```
for i = 0 to 15
dci ← carry_out(RA4xi:63 + RB4xi:63)
c ← 4(dci) || 4(dci) || ... || 4(dci)
RT ← (~c) & 0x6666_6666_6666_6666
```

The contents of register RA are added to the contents of register RB. Sixteen carry bits are produced, one for each carry out of decimal position \( n \) (bit position \( 4\times n \)).

A doubleword is composed from the 16 carry bits, and placed into RT. The doubleword consists of a decimal six (0b0110) in every decimal digit position for which the corresponding carry bit is 0, and a zero (0b0000) in every position for which the corresponding carry bit is 1.

**Special Registers Altered:**

None

---

**Programming Note**

*addg6s* can be used to add or subtract two BCD operands. In these examples it is assumed that \( r0 \) contains 0x666...666. (BCD data formats are described in Section 5.3.)

Addition of the unsigned BCD operand in register RA to the unsigned BCD operand in register RB can be accomplished as follows.

```plaintext
add r1,RA,r0
add r2,r1,RB
addg6s RT,r1,RB
subf RT,RT,r2   # RT = RA + BCD RB
```

Subtraction of the unsigned BCD operand in register RA from the unsigned BCD operand in register RB can be accomplished as follows. (In this example it is assumed that RB is not register 0.)

```plaintext
addi r1,RB,1
nor r2,RA,RA   # one's complement of RA
add r3,r1,r2
addg6s RT,r1,r2
subf RT,RT,r3   # RT = RB - BCD RA
```

Additional instructions are needed to handle signed BCD operands, and BCD operands that occupy more than one register (e.g., unsigned BCD operands that have more than 16 decimal digits).
### 3.3.16 Byte-Reverse Instructions

**Byte-Reverse Halfword X-form**

\[ \text{brh} \quad \text{RA,RS} \]

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>6</th>
<th>RS</th>
<th>11</th>
<th>RA</th>
<th>16</th>
<th>219</th>
<th>/</th>
</tr>
</thead>
<tbody>
<tr>
<td>RA [=] (RS)</td>
<td>8:35</td>
<td>| (RS)</td>
<td>0:7</td>
<td>| (RS)</td>
<td>24:31</td>
<td>| (RS)</td>
<td>16:23</td>
<td>| (RS)</td>
</tr>
</tbody>
</table>

The contents of bits 0:15 of register RS are placed into bits 0:15 of register RA in byte-reversed order.

The contents of bits 16:31 of register RS are placed into bits 16:31 of register RA in byte-reversed order.

The contents of bits 32:47 of register RS are placed into bits 32:47 of register RA in byte-reversed order.

The contents of bits 48:63 of register RS are placed into bits 48:63 of register RA in byte-reversed order.

**Special Registers Altered:**

None

**Byte-Reverse Word X-form**

\[ \text{brw} \quad \text{RA,RS} \]

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>6</th>
<th>RS</th>
<th>11</th>
<th>RA</th>
<th>16</th>
<th>155</th>
<th>/</th>
</tr>
</thead>
<tbody>
<tr>
<td>RA [=] (RS)</td>
<td>24:31</td>
<td>| (RS)</td>
<td>16:23</td>
<td>| (RS)</td>
<td>8:35</td>
<td>| (RS)</td>
<td>0:7</td>
<td>| (RS)</td>
</tr>
</tbody>
</table>

The contents of bits 0:31 of register RS are placed into bits 0:31 of register RA in byte-reversed order.

The contents of bits 32:63 of register RS are placed into bits 32:63 of register RA in byte-reversed order.

**Special Registers Altered:**

None

**Byte-Reverse Doubleword X-form**

\[ \text{brd} \quad \text{RA,RS} \]

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>6</th>

</thead>
<tbody>
<tr>
<td>RA [=] (RS)</td>
<td>56:63</td>
<td>| (RS)</td>
<td>48:55</td>
<td>| (RS)</td>
<td>40:47</td>
<td>| (RS)</td>
<td>32:39</td>
<td>| (RS)</td>
</tr>
</tbody>
</table>

The contents of register RS are placed into register RA in byte-reversed order.

**Special Registers Altered:**

None
### 3.3.17 Move To/From Vector-Scalar Register Instructions

#### Move From VSR Doubleword X-form

**mfvsrd** RA,XS

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>6</th>
<th>S</th>
<th>RA</th>
<th>16</th>
<th>///</th>
<th>21</th>
<th>51</th>
<th>64</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>51</td>
<td>64</td>
</tr>
</tbody>
</table>

```plaintext
if SX=0 & MSR.FP=0 then FP_Unavailable()
if SX=1 & MSR.VEC=0 then Vector_Unavailable()
```

GPR[RA] ← VSR[(32×SX+S)].dword[0]

Let XS be the value $32 \times SX + S$.

The contents of doubleword element 0 of VSR[XS] are placed into GPR[RA].

For SX=0, **mfvsrd** is treated as a Floating-Point instruction in terms of resource availability.

For SX=1, **mfvsrd** is treated as a Vector instruction in terms of resource availability.

**Extended Mnemonics:**

Extended mnemonics for Move From VSR Doubleword:

<table>
<thead>
<tr>
<th>Extended mnemonic:</th>
<th>Equivalent to:</th>
</tr>
</thead>
<tbody>
<tr>
<td>mfiprd RA,FRS</td>
<td>mfvsrd RA,FRS</td>
</tr>
<tr>
<td>mfvr d RA, VRS</td>
<td>mfvsrd RA, VRS+32</td>
</tr>
</tbody>
</table>

**Special Registers Altered:**

None

**Data Layout for mfvsrd**

```plaintext
src
tgt
```

<table>
<thead>
<tr>
<th>src</th>
<th>tgt</th>
</tr>
</thead>
<tbody>
<tr>
<td>VSR[XS].dword[0]</td>
<td>GPR[RA]</td>
</tr>
</tbody>
</table>

#### Move From VSR Lower Doubleword X-form

**mfvsrld** RA,XS

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>6</th>
<th>S</th>
<th>RA</th>
<th>16</th>
<th>///</th>
<th>21</th>
<th>307</th>
<th>64</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>307</td>
<td>64</td>
</tr>
</tbody>
</table>

```plaintext
if SX=0 & MSR.VSX=0 then VSX_Unavailable()
if SX=1 & MSR.VEC=0 then Vector_Unavailable()
```

GPR[RA] ← VSR[(32×SX+S)].dword[1]

Let XS be the value $32 \times SX + S$.

The contents of doubleword 1 of VSR[XS] are placed into GPR[RA].

For SX=0, **mfvsrld** is treated as a VSX instruction in terms of resource availability.

For SX=1, **mfvsrld** is treated as a Vector instruction in terms of resource availability.

3.3.18 Move To/From System Register Instructions

The *Move To Condition Register Fields* instruction has a preferred form; see Section 1.8.1, “Preferred Instruction Forms” on page 24. In the preferred form, the FXM field satisfies the following rule:

- Exactly one bit of the FXM field is set to 1.

**Extended mnemonics**

Extended mnemonics are provided for the *mtspr* and *mfspr* instructions so that they can be coded with the SPR name as part of the mnemonic rather than as a numeric operand. An extended mnemonic is provided for the *mtcrf* instruction for compatibility with old software (written for a version of the architecture that preceded Version 2.00) that uses it to set the entire Condition Register. Some of these extended mnemonics are shown as examples with the relevant instructions. See Appendix C, “Assembler Extended Mnemonics” on page 1011 for additional extended mnemonics.

</tbody>
</table>

1. Note that the order of the two 5-bit halves of the SPR number is reversed.
2. Accesses to these registers are no-ops; see Section 1.3.3, “Reserved Fields, Reserved Values, and Reserved SPRs”

The SPR field denotes a Special Purpose Register, encoded as shown in the table below. If the SPR field contains a value from 808 through 811, the instruction specifies a reserved SPR, and is treated as a no-op; see Section 1.3.3, “Reserved Fields, Reserved Values, and Reserved SPRs”. Otherwise, unless the SPR field contains 13 (denoting the AMR), the contents of register RS are placed into the designated Special Purpose Register. For Special Purpose Registers that are 32 bits long, the low-order 32 bits of RS are placed into the SPR.

The AMR (Authority Mask Register) is used for “storage protection.” This use, and operation of *mtspr* for the AMR, are described in Book III.

<table>

<td>MMCR2</td>
</tr>
<tr>
<td>770</td>
<td>11000 000100</td>
<td>MMCR3</td>
</tr>
</tbody>
</table>

1. Note that the order of the two 5-bit halves of the SPR number is reversed.
2. Accesses to these registers are no-ops; see Section 1.3.3, “Reserved Fields, Reserved Values, and Reserved SPRs”

If execution of this instruction is attempted specifying an SPR number that is not shown above, one of the following occurs:

- If spr<sub>4</sub> = 0, the illegal instruction error handler is invoked.
- If spr<sub>4</sub> = 1, the system privileged instruction error handler is invoked.

A complete description of this instruction can be found in Book III.

**Special Registers Altered:**

See above
Extended Mnemonics:

Examples of extended mnemonics for *Move To Special Purpose Register*:

<table>
<thead>
<tr>
<th>Extended mnemonic:</th>
<th>Equivalent to:</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>mtppr32 Rx</td>
<td>mtspr 898,Rx</td>
</tr>
</tbody>
</table>

---

**Programming Note**

The AMR is part of the “context” of the program (see Book III). Therefore modification of the AMR requires “synchronization” by software. For this reason, most operating systems provide a system library program that application programs can use to modify the AMR.

---

**Compiler and Assembler Note**

For the *mtspr* and *mfspr* instructions, the SPR number coded in Assembler language does not appear directly as a 10-bit binary number in the instruction. The number coded is split into two 5-bit halves that are reversed in the instruction, with the high-order 5 bits appearing in bits 16:20 of the instruction and the low-order 5 bits in bits 11:15.
Move From Special Purpose Register

XFX-form

\[ \text{mfspr} \text{ RT,SPR} \]

\[
\begin{array}{cccc}
0 & 31 & 6 & \text{RT} \\
1 & 31 & 11 & \text{spr} \\
2 & 31 & 21 & 339 \\
3 & 31 & 31 & 32 \\
\end{array}
\]

\[
h \leftarrow \text{spr}_{5:9} \ || \ \text{spr}_{0:4}
\]

\[
\text{switch} (n)
\]

\[
\begin{cases}
\text{case} (800, 809, 810, 811): & \text{default:} \\
\text{if} \ |\text{length}(\text{SPR}(n))| = 64 \text{ then} & \text{RT} \leftarrow \text{SPR}(n) \\
\text{else} & \text{RT} \leftarrow 32 \ || \ \text{SPR}(n)
\end{cases}
\]

The SPR field denotes a Special Purpose Register, encoded as shown in the table below. If the SPR field contains a value from 808 through 811, the instruction specifies a reserved SPR, and is treated as a no-op; see Section 1.3.3, "Reserved Fields, Reserved Values, and Reserved SPRs". Otherwise, the contents of the designated Special Purpose Register are placed into register RT. For Special Purpose Registers that are 32 bits long, the low-order 32 bits of RT receive the contents of the Special Purpose Register and the high-order 32 bits of RT are set to zero.

mask ← 4(FXM0) || 4(FXM1) || ... || 4(FXM7)
CR ← (RS)32:63 & mask | (CR & ¬mask)

The contents of bits 32:63 of register RS are placed into the Condition Register under control of the field mask specified by FXM. The field mask identifies the 4-bit fields affected. Let i be an integer in the range 0-7. If FXMi = 1 then CR field i (CR bits 4×i+32:4×i+33) is set to the contents of the corresponding field of the low-order 32 bits of RS.

Special Registers Altered:
CR fields selected by mask

Extended Mnemonics:
Example of extended mnemonics for Move To Condition Register Fields:

**Extended mnemonic:**

```
mect  Rx
```

**Equivalent to:**

```
mctr  0xFF,Rx
```
**Move From One Condition Register Field XFX-form**

```
<table>
<thead>
<tr>
<th>mfocrf</th>
<th>RT,FXM</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RT</td>
</tr>
<tr>
<td>0</td>
<td>FXM</td>
</tr>
</tbody>
</table>
```

RT ← undefined

```plaintext
count ← 0
do i = 0 to 7
   if FXMi = 1 then
      n ← i
   end if
   count ← count + 1
if count = 1 then
   RT ← 640
   RT4×n+32:4×n+35 ← CR4×n+32:4×n+35
```

If exactly one bit of the FXM field is set to 1, let n be the position of that bit in the field \((0 \leq n \leq 7)\). The contents of CR field \(n\) (CR bits \(4×n+32:4×n+35\)) are placed into bits \(4×n+32:4×n+35\) of register RT, and the contents of the remaining bits of register RT are undefined. Otherwise, the contents of register RT are undefined.

If exactly one bit of the FXM field is set to 1, the contents of the remaining bits of register RT are set to 0's instead of being undefined as specified above.

**Special Registers Altered:**

None

**Programming Note**

Warning: `mfocrf` is not backward compatible with processors that comply with versions of the architecture that precede Version 2.08. Such processors may not set to 0 the bits of register RT that do not correspond to the specified CR field. If programs that depend on this clearing behavior are run on such processors, the programs may get incorrect results.

The POWER4, POWER5, POWER7 and POWER8 processors set to 0's all bytes of register RT other than the byte that contains the specified CR field. In the byte that contains the CR field, bits other than those containing the CR field may or may not be set to 0s.
### Set Boolean X-form

\[
\text{setb} \quad RT, BFA
\]

<table>
<thead>
<tr>
<th>31</th>
<th>RT</th>
<th>BFA</th>
<th>14</th>
<th>16</th>
<th>21</th>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>128</td>
<td>1</td>
</tr>
</tbody>
</table>

- If \( CR_{BFA+32} = 1 \) then
  \[ RT \leftarrow 0xFFFF_FFFF_FFFF_FFFF \]
- Else if \( CR_{BFA+33} = 1 \) then
  \[ RT \leftarrow 0x0000_0000_0000_0001 \]
- Else
  \[ RT \leftarrow 0x0000_0000_0000_0000 \]

If the contents of bit 0 of CR field BFA are equal to 0b1, the contents of register RT are set to \( 0xFFFF_FFFF_FFFF_FFFF \).

Otherwise, if the contents of bit 1 of CR field BFA are equal to 0b1, the contents of register RT are set to \( 0x0000_0000_0000_0001 \).

Otherwise, the contents of register RT are set to \( 0x0000_0000_0000_0000 \).

**Special Registers Altered:** None

### Set Boolean Condition X-form

\[
\text{setbc} \quad RT, BI
\]

<table>
<thead>
<tr>
<th>31</th>
<th>RT</th>
<th>BI</th>
<th>14</th>
<th>16</th>
<th>21</th>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>384</td>
<td>1</td>
</tr>
</tbody>
</table>

- \( RT = (CR_{BI}=1) ? 1 : 0 \)

If bit \( BI \) of the CR contains a 1, register RT is set to 1. Otherwise, register RT is set to 0.

**Special Registers Altered:** None

### Set Boolean Condition Reverse X-form

\[
\text{setbcr} \quad RT, BI
\]

<table>
<thead>
<tr>
<th>31</th>
<th>RT</th>
<th>BI</th>
<th>14</th>
<th>16</th>
<th>21</th>
<th>31</th>
</tr>
</thead>
<tbody>

<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>416</td>
<td>1</td>
</tr>
</tbody>
</table>

- \( RT = (CR_{BI}=1) ? 0 : 1 \)

If bit \( BI \) of the CR contains a 1, register RT is set to 0. Otherwise, register RT is set to 1.

**Special Registers Altered:** None

### Set Negative Boolean Condition X-form

\[
\text{setnbc} \quad RT, BI
\]

<table>
<thead>
<tr>
<th>31</th>
<th>RT</th>
<th>BI</th>
<th>14</th>
<th>16</th>
<th>21</th>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>448</td>
<td>1</td>
</tr>
</tbody>
</table>

- \( RT = (CR_{BI}=1) ? -1 : 0 \)

If bit \( BI \) of the CR contains a 1, register RT is set to -1. Otherwise, register RT is set to 0.

**Special Registers Altered:** None

### Set Negative Boolean Condition Reverse X-form

\[
\text{setnbcr} \quad RT, BI
\]

<table>
<thead>
<tr>
<th>31</th>
<th>RT</th>
<th>BI</th>
<th>14</th>

1. Value must not correspond to a Branch instruction, an rfebb instruction, a context synchronizing instruction other than isync, or a "Service Processor Attention" instruction

No operation is performed.

Special Registers Altered:

None

Programming Note

The pnop instruction behaves as a b $+8 instruction regardless of its suffix. However, it does not cause any side effects such as modification of the Come From Address Register. (see Section 9.2 of Book III).

Programming Note

If the value in the suffix of a pnop instruction corresponds to a Branch instruction, an rfebb instruction, a context synchronizing instruction other than isync, or a "Service Processor Attention" instruction, the instruction form is invalid. The behavior associated with invalid form instructions is described in Section 1.8.2 on page 24. rfebb and isync are defined in Book II: Power ISA Virtual Environment Architecture. Context synchronization and other context synchronizing instructions are defined in Book III: Power ISA Operating Environment Architecture. Service Processor Attention is a reserved instruction; see Appendix C, "Reserved Instructions" on page 1347.)

This restriction eases hardware implementation complexity.

Engineering Note

Because the list of word instructions that must not be used as the suffix of pnop may change in the future, hardware should treat these invalid instruction forms of pnop either as a no-op or as an illegal instruction. This treatment enhances software compatibility. The choice may vary according to which of the word instructions is used as the suffix.
Chapter 4. Floating-Point Facility

4.1 Floating-Point Facility Overview

This chapter describes the registers and instructions that make up the Floating-Point Facility.

The processor (augmented by appropriate software support, where required) implements a floating-point system compliant with the ANSI/IEEE Standard 754-1985, “IEEE Standard for Binary Floating-Point Arithmetic” (hereafter referred to as “the IEEE standard”). That standard defines certain required “operations” (addition, subtraction, etc.). Herein, the term “floating-point operation” is used to refer to one of these required operations and to additional operations defined (e.g., those performed by Multiply-Add or Reciprocal Estimate instructions). A Non-IEEE mode is also provided. This mode, which may produce results not in strict compliance with the IEEE standard, allows shorter latency.

Instructions are provided to perform arithmetic, rounding, conversion, comparison, and other operations in floating-point registers; to move floating-point data between storage and these registers; and to manipulate the Floating-Point Status and Control Register explicitly.

These instructions are divided into two categories.

• computational instructions
  The computational instructions are those that perform addition, subtraction, multiplication, division, extracting the square root, rounding, conversion, comparison, and combinations of these operations. These instructions provide the floating-point operations. They place status information into the Floating-Point Status and Control Register. They are the instructions described in Sections 4.6.6 through 4.6.8.

• non-computational instructions
  The non-computational instructions are those that perform loads and stores, move the contents of a floating-point register to another floating-point register possibly altering the sign, manipulate the Floating-Point Status and Control Register explicitly, and select the value from one of two floating-point registers based on the value in a third floating-point register. The operations performed by these instructions are not considered floating-point operations. With the exception of the instructions that manipulate the Floating-Point Status and Control Register explicitly, they do not alter the Floating-Point Status and Control Register. They are the instructions described in Sections 4.6.2 through 4.6.5, and 4.6.10.

A floating-point number consists of a signed exponent and a signed significand. The quantity expressed by this number is the product of the significand and the number $2^{\text{exponent}}$. Encodings are provided in the data format to represent finite numeric values, $\pm\text{Infinity}$, and values that are “Not a Number” (NaN). Operations involving infinities produce results obeying traditional mathematical conventions. NaNs have no mathematical interpretation. Their encoding permits a variable diagnostic information field. They may be used to indicate such things as uninitialized variables and can be produced by certain invalid operations.

There is one class of exceptional events that occur during instruction execution that is unique to the Floating-Point Facility: the Floating-Point Exception. Floating-point exceptions are signaled with bits set in the Floating-Point Status and Control Register (FPSCR). They can cause the system floating-point enabled exception error handler to be invoked, precisely or imprecisely, if the proper control bits are set.

Floating-Point Exceptions

The following floating-point exceptions are detected by the processor:

• Invalid Operation Exception (VX)
  SNaN (VXSNaN)
  Infinity–Infinity (VXSI)
  Infinity–Infinity (VXDI)
  Zero–Zero (VXZDZ)
  Infinity–Zero (VXIMZ)
  Invalid Compare (VXVC)
  Software-Defined Condition (VXSOFT)
  Invalid Square Root (VXSQRT)

Each floating-point exception, and each category of Invalid Operation Exception, has an exception bit in the FPSCR. In addition, each floating-point exception has a corresponding enable bit in the FPSCR. See Section 4.2.2, “Floating-Point Status and Control Register” on page 132 for a description of these exception and enable bits, and Section 4.4, “Floating-Point Exceptions” on page 140 for a detailed discussion of floating-point exceptions, including the effects of the enable bits.

4.2 Floating-Point Facility Registers

4.2.1 Floating-Point Registers

Implementations of this architecture provide 32 floating-point registers (FPRs). The floating-point instruction formats provide 5-bit fields for specifying the FPRs to be used in the execution of the instruction. The FPRs are numbered 0-31. See Figure 45 on page 132.

Each FPR contains 64 bits that support the floating-point double format. Every instruction that interprets the contents of an FPR as a floating-point value uses the floating-point double format for this interpretation.

The computational instructions, and the Move and Select instructions, operate on data located in FPRs and, with the exception of the Compare instructions, place the result value into an FPR and optionally (when \( Rc=1 \)) place status information into the Condition Register.

Load Double and Store Double instructions are provided that transfer 64 bits of data between storage and the FPRs with no conversion. Load Single instructions are provided to transfer and convert floating-point values in floating-point single format from storage to the same value in floating-point double format in the FPRs. Store Single instructions are provided to transfer and convert floating-point values in floating-point double format from the FPRs to the same value in floating-point single format in storage.

Instructions are provided that manipulate the Floating-Point Status and Control Register and the Condition Register explicitly. Some of these instructions copy data from an FPR to the Floating-Point Status and Control Register or vice versa.

The computational instructions and the Select instruction accept values from the FPRs in double format. For single-precision arithmetic instructions, all input values must be representable in single format; if they are not, the result placed into the target FPR, and the setting of status bits in the FPSCR and in the Condition Register (if \( Rc=1 \)), are undefined.

<table>
<thead>
<tr>
<th>Bit(s)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0:31</td>
<td>Reserved</td>
</tr>
<tr>
<td>29:31</td>
<td>Decimal Rounding Mode (( DRN ))</td>
</tr>
<tr>
<td></td>
<td>See Section 5.2.1, “DFP Usage of Floating-Point Registers” on page 188.</td>
</tr>
<tr>
<td>32</td>
<td>Floating-Point Exception Summary (( FX ))</td>
</tr>
<tr>
<td></td>
<td>Every floating-point instruction, except ( mtfsf ) and ( mtfsf ), implicitly sets ( FX ) to 1 if that instruction causes any of the floating-point exception bits in the FPSCR to change from 0 to 1. ( mcrfs ), ( mtfsi ), ( mtfsi ), ( mtfsb0 ), and ( mtfsb1 ) can alter ( FX ) explicitly.</td>
</tr>
</tbody>
</table>
Floating-Point Enabled Exception Summary (FX)
This bit is the OR of all the floating-point exception bits masked by their respective enable bits. mcrfs, mtsfsfi, mtsfsf, mtfsb0, and mtfsb1 cannot alter FX explicitly.

Floating-Point Invalid Operation Exception Summary (XX)
This bit is the OR of all the Invalid Operation exception bits. mcrfs, mtsfsfi, mtsfsf, mtfsb0, and mtfsb1 cannot alter XX explicitly.

Floating-Point Overflow Exception (OX)
See Section 4.4.3, “Overflow Exception” on page 143.

Floating-Point Underflow Exception (UX)
See Section 4.4.4, “Underflow Exception” on page 144.

Floating-Point Zero Divide Exception (ZX)
See Section 4.4.2, “Zero Divide Exception” on page 142.

Floating-Point Inexact Exception (XX)
See Section 4.4.5, “Inexact Exception” on page 144.

XX is a sticky version of FI (see below). Thus the following rules completely describe how XX is set by a given instruction.

- If the instruction affects FI, the new value of XX is obtained by ORing the old value of XX with the new value of FI.
- If the instruction does not affect FI, the value of XX is unchanged.

Floating-Point Invalid Operation Exception (SNaN) (VXSNAN)
See Section 4.4.1, “Invalid Operation Exception” on page 142.

Floating-Point Invalid Operation Exception (∞ - ∞) (VX1S1)
See Section 4.4.1.

Floating-Point Invalid Operation Exception (∞ + ∞) (VX1DI)
See Section 4.4.1.

Floating-Point Invalid Operation Exception (0 ÷ 0) (VX2D2)
See Section 4.4.1.

Floating-Point Invalid Operation Exception (∞ ÷ 0) (VX1MZ)
See Section 4.4.1.

Floating-Point Invalid Operation Exception (Invalid Compare) (VXVC)
See Section 4.4.1.

Floating-Point Fraction Rounded (FR)
The last Arithmetic or Rounding and Conversion instruction incremented the fraction during rounding. See Section 4.3.6, “Rounding” on page 139. This bit is not sticky.

Floating-Point Fraction Inexact (FI)
The last Arithmetic or Rounding and Conversion instruction either produced an inexact result during rounding or caused a disabled Overflow Exception. See Section 4.3.6. This bit is not sticky.

See the definition of XX, above, regarding the relationship between FI and XX.

Floating-Point Result Flags (FPRF)
Arithmetic, rounding, and Convert From Integer instructions set this field based on the result placed into the target register and on the target precision, except that if any portion of the result is undefined then the value placed into FPRF is undefined. Floating-point Compare instructions set this field based on the relative values of the operands being compared. For Convert To Integer instructions, the value placed into FPRF is undefined. Additional details are given below.

A single-precision operation that produces a denormalized result sets FPRF to indicate a denormalized number. When possible, single-precision denormalized numbers are represented in normalized double format in the target register.

Floating-Point Result Class Descriptor (C)
Arithmetic, rounding, and Convert From Integer instructions may set this bit with the FPCC bits, to indicate the class of the result as shown in Figure 47 on page 135.
Floating-Point Condition Code (FPCC)
Floating-point Compare instructions set one of the FPCC bits to 1 and the other three FPCC bits to 0. Arithmetic, rounding, and Convert From Integer instructions may set the FPCC bits with the C bit, to indicate the class of the result as shown in Figure 47 on page 135. Note that in this case the high-order three bits of the FPCC retain their relational significance indicating that the value is less than, greater than, or equal to zero.

Floating-Point Less Than or Negative (FL or <)
Floating-Point Greater Than or Positive (FG or >)
Floating-Point Equal or Zero (FE or =)
Floating-Point Unordered or NaN (FU or ?)
Reserved
Floating-Point Invalid Operation Exception (Software-Defined Condition) (VXSOFT)
This bit can be altered only by mcrfs, mtfsfi, mtfsf, mtfsb0, or mtfsb1. See Section 4.4.1.

Programming Note
FPSCR\textsubscript{VXSOFT} can be used by software to indicate the occurrence of an arbitrary, software-defined, condition that is to be treated as an Invalid Operation Exception. For example, the bit could be set by a program that computes a base 10 logarithm if the supplied input is negative.

Floating-Point Invalid Operation Exception (Invalid Square Root) (VXSQRT)
See Section 4.4.1.
Floating-Point Invalid Operation Exception (Invalid Integer Convert) (VXCVI)
See Section 4.4.1.
Floating-Point Invalid Operation Exception Enable (VE)
See Section 4.4.1.
Floating-Point Overflow Exception Enable (OE)
See Section 4.4.3, “Overflow Exception” on page 143.
Floating-Point Underflow Exception Enable (UE)
See Section 4.4.4, “Underflow Exception” on page 144.
Floating-Point Zero Divide Exception Enable (ZE)
See Section 4.4.2, “Zero Divide Exception” on page 142.

Floating-Point Inexact Exception Enable (XE)
See Section 4.4.5, “Inexact Exception” on page 144.
Floating-Point Non-IEEE Mode (NI)
Floating-point non-IEEE mode is optional. If floating-point non-IEEE mode is not implemented, this bit is treated as reserved, and the remainder of the definition of this bit does not apply.

If floating-point non-IEEE mode is implemented, this bit has the following meaning.
0 The processor is not in floating-point non-IEEE mode (i.e., all floating-point operations conform to the IEEE standard).
1 The processor is in floating-point non-IEEE mode.

When the processor is in floating-point non-IEEE mode, the remaining FPSCR bits may have meanings different from those given in this document, and floating-point operations need not conform to the IEEE standard. The effects of executing a given floating-point instruction with FPSCR\textsubscript{NI}=1, and any additional requirements for using non-IEEE mode, are implementation-dependent. The results of executing a given instruction in non-IEEE mode may vary between implementations, and between different executions on the same implementation.

Programming Note
When the processor is in floating-point non-IEEE mode, the results of floating-point operations may be approximate, and performance for these operations may be better, more predictable, or less data-dependent than when the processor is not in non-IEEE mode. For example, in non-IEEE mode an implementation may return 0 instead of a denormalized number, and may return a large number instead of an infinity.

Floating-Point Rounding Control (RN)
See Section 4.3.6, “Rounding” on page 139.
00 Round to nearest
01 Round toward zero
10 Round toward +Infinity
11 Round toward -Infinity
4.3 Floating-Point Data

4.3.1 Data Format

This architecture defines the representation of a floating-point value in two different binary fixed-length formats. The format may be a 32-bit single format for a single-precision value or a 64-bit double format for a double-precision value. The single format may be used for data in storage. The double format may be used for data in storage and for data in floating-point registers.

The lengths of the exponent and the fraction fields differ between these two formats. The structure of the single and double formats is shown below.

![Figure 48. Floating-point single format](image)

![Figure 49. Floating-point double format](image)

Values in floating-point format are composed of three fields:

- **S**: sign bit
- **EXP**: exponent+bias
- **FRACTION**: fraction

Representation of numeric values in the floating-point formats consists of a sign bit (S), a biased exponent (EXP), and the fraction portion (FRACTION) of the significand. The significand consists of a leading implied bit concatenated on the right with the FRACTION. This leading implied bit is 1 for normalized numbers and 0 for denormalized numbers and is located in the unit bit position (i.e., the first bit to the left of the binary point). Values representable within the two floating-point formats can be specified by the parameters listed in Figure 50.

![Figure 50. IEEE floating-point fields](image)

The architecture requires that the FPRs of the Floating-Point Facility support the floating-point double format only.

4.3.2 Value Representation

This architecture defines numeric and non-numeric values representable within each of the two supported formats. The numeric values are approximations to the real numbers and include the normalized numbers, denormalized numbers, and zero values. The non-numeric values representable are the infinities and the Not a Numbers (NaNs). The infinities are adjoined to the real numbers, but are not numbers themselves, and the standard rules of arithmetic do not hold when they are used in an operation. They are related to the real numbers by order alone. It is possible however to define restricted operations among numbers and infinities as defined below. The relative location on the real number line for each of the defined entities is shown in Figure 51.

![Figure 51. Approximation to real numbers](image)

The NaNs are not related to the numeric values or infinities by order or value but are encodings used to convey diagnostic information such as the representation of uninitialized variables.

The following is a description of the different floating-point values defined in the architecture:

**Binary floating-point numbers**

Machine representable values used as approximations to real numbers. Three categories of numbers are supported: normalized numbers, denormalized numbers, and zero values.
**Normalized numbers** (± NOR)
These are values that have a biased exponent value in the range:

- 1 to 254 in single format
- 1 to 2046 in double format

They are values in which the implied unit bit is 1. Normalized numbers are interpreted as follows:

\[ \text{NOR} = (-1)^s \times 2^E \times (1.\text{fraction}) \]

where \( s \) is the sign, \( E \) is the unbiased exponent, and \( 1.\text{fraction} \) is the significand, which is composed of a leading unit bit (implied bit) and a fraction part.

The ranges covered by the magnitude (\( M \)) of a normalized floating-point number are approximately equal to:

- **Single Format:**
  \[ 1.2 \times 10^{-38} \leq M \leq 3.4 \times 10^{38} \]
- **Double Format:**
  \[ 2.2 \times 10^{-308} \leq M \leq 1.8 \times 10^{308} \]

**Zero values** (± 0)
These are values that have a biased exponent value of zero and a fraction value of zero. Zeros can have a positive or negative sign. The sign of zero is ignored by comparison operations (i.e., comparison regards +0 as equal to –0).

**Denormalized numbers** (± 0)
These are values that have a biased exponent value of zero and a nonzero fraction value. They are nonzero numbers smaller in magnitude than the representable normalized numbers. They are values in which the implied unit bit is 0. Denormalized numbers are interpreted as follows:

\[ \text{DEN} = (-1)^s \times 2^{E_{\text{min}}} \times (0.\text{fraction}) \]

where \( E_{\text{min}} \) is the minimum representable exponent value (−126 for single-precision, −1022 for double-precision).

**Infinities** (± ∞)
These are values that have the maximum biased exponent value:

- 255 in single format
- 2047 in double format

and a zero fraction value. They are used to approximate values greater in magnitude than the maximum normalized value.

Infinity arithmetic is defined as the limiting case of real arithmetic, with restricted operations defined among numbers and infinities. Infinities and the real numbers can be related by ordering in the affine sense:

\(-∞ < \text{every finite number} < +∞\)

Arithmetic on infinities is always exact and does not signal any exception, except when an exception occurs due to the invalid operations as described in Section 4.4.1, “Invalid Operation Exception” on page 142.

For comparison operations, +Infinity compares equal to +Infinity and -Infinity compares equal to -Infinity.

**Not a Numbers** (NaNs)
These are values that have the maximum biased exponent value and a nonzero fraction value. The sign bit is ignored (i.e., NaNs are neither positive nor negative). If the high-order bit of the fraction field is 0 then the NaN is a Signaling NaN; otherwise it is a Quiet NaN.

Signaling NaNs are used to signal exceptions when they appear as operands of computational instructions. Quiet NaNs are used to represent the results of certain invalid operations, such as invalid arithmetic operations on infinities or on NaNs, when Invalid Operation Exception is disabled (\( \text{VE} = 0 \)). Quiet NaNs propagate through all floating-point operations except ordered comparison, Floating Round to Single-Precision, and conversion to integer. Quiet NaNs do not signal exceptions, except for ordered comparison and conversion to integer operations. Specific encodings in QNaNs can thus be preserved through a sequence of floating-point operations, and used to convey diagnostic information to help identify results from invalid operations.

When a QNaN is the result of a floating-point operation because one of the operands is a NaN or because a QNaN was generated due to a disabled Invalid Operation Exception, then the following rule is applied to determine the NaN with the high-order fraction bit set to 1 that is to be stored as the result.

If \( \text{FRA} \) is a NaN
then \( \text{FRT} \leftarrow \text{FRA} \)
else if \( \text{FRB} \) is a NaN
then if instruction is \( \text{frsp} \)
    then \( \text{FRT} \leftarrow \text{FRB} \)
    else \( \text{FRT} \leftarrow \text{FRB} \)
else if \( \text{FRC} \) is a NaN
then \( \text{FRT} \leftarrow \text{FRC} \)
else if generated QNaN
then \( \text{FRT} \leftarrow \text{generated QNaN} \)

If the operand specified by \( \text{FRA} \) is a NaN, then that NaN is stored as the result. Otherwise, if the operand specified by \( \text{FRB} \) is a NaN (if the instruction specifies an \( \text{FRB} \) operand), then that NaN is stored as the result, with the low-order 29 bits of the result set to 0 if the instruction is \( \text{frsp} \). Otherwise, if the operand specified by \( \text{FRC} \) is a NaN (if the instruction specifies an \( \text{FRC} \) operand), then that NaN is stored as the result. Otherwise, if a QNaN was generated due to a disabled Invalid Operation Exception, then that QNaN is stored as the result. If a QNaN is to be generated as a result, then the QNaN generated has a sign bit of 0, an exponent field of all 1s, and a high-order fraction bit of 1 with all other fraction bits 0. Any instruction that generates a QNaN as
the result of a disabled Invalid Operation Exception generates this QNaN (i.e., \texttt{0x7FF8_0000_0000_0000}).

A double-precision NaN is considered to be representable in single format if and only if the low-order 29 bits of the double-precision NaN's fraction are zero.

### 4.3.3 Sign of Result

The following rules govern the sign of the result of an arithmetic, rounding, or conversion operation, when the operation does not yield an exception. They apply even when the operands or results are zeros or infinities.

- The sign of the result of an add operation is the sign of the operand having the larger absolute value. If both operands have the same sign, the sign of the result of an add operation is the same as the sign of the operands. The sign of the result of the subtract operation \( x - y \) is the same as the sign of the result of the add operation \( x + (-y) \).

When the sum of two operands with opposite sign, or the difference of two operands with the same sign, is exactly zero, the sign of the result is positive in all rounding modes except Round toward \( -\infty \), in which mode the sign is negative.

- The sign of the result of a multiply or divide operation is the Exclusive OR of the signs of the operands.

- The sign of the result of a Square Root or Reciprocal Square Root Estimate operation is always positive, except that the square root of \(-0\) is \(-0\) and the reciprocal square root of \(-0\) is \(-\infty\).

- The sign of the result of a Round to Single-Precision, or Convert From Integer, or Round to Integer operation is the sign of the operand being converted.

For the Multiply-Add instructions, the rules given above are applied first to the multiply operation and then to the add or subtract operation (one of the inputs to the add or subtract operation is the result of the multiply operation).

### 4.3.4 Normalization and Denormalization

The intermediate result of an arithmetic or \texttt{frsp} instruction may require normalization and/or denormalization as described below. Normalization and denormalization do not affect the sign of the result.

When an arithmetic or rounding instruction produces an intermediate result which carries out of the significand, or in which the significand is nonzero but has a leading zero bit, it is not a normalized number and must be normalized before it is stored. For the carry-out case, the significand is shifted right one bit, with a one shifted into the leading significand bit, and the exponent is incremented by one. For the leading-zero case, the significand is shifted left while decremented its exponent by one for each bit shifted, until the leading significant bit becomes one. The Guard bit and the Round bit (see Section 4.5.1, “Execution Model for IEEE Operations” on page 145) participate in the shift with zeros shifted into the Round bit. The exponent is regarded as if its range were unlimited.

After normalization, or if normalization was not required, the intermediate result may have a nonzero significand and an exponent value that is less than the minimum value that can be represented in the format specified for the result. In this case, the intermediate result is said to be “Tiny” and the stored result is determined by the rules described in Section 4.4.4, “Underflow Exception”. These rules may require denormalization.

A number is denormalized by shifting its significand right while incrementing its exponent by 1 for each bit shifted, until the exponent is equal to the format’s minimum value. If any significant bits are lost in this shifting process then “Loss of Accuracy” has occurred (See Section 4.4.4, “Underflow Exception” on page 144) and Underflow Exception is signaled.

### 4.3.5 Data Handling and Precision

Most of the Floating-Point Facility Architecture, including all computational, Move, and Select instructions, use the floating-point double format to represent data in the FPRs. Single-precision and integer-valued operands may be manipulated using double-precision operations. Instructions are provided to coerce these values from a double format operand. Instructions are also provided for manipulations which do not require double-precision. In addition, instructions are provided to access a true single-precision representation in storage, and a fixed-point integer representation in GPRs.

#### 4.3.5.1 Single-Precision Operands

For single format data, a format conversion from single to double is performed when loading from storage into an FPR and a format conversion from double to single is performed when storing from an FPR to storage. No floating-point exceptions are caused by these instructions. An instruction is provided to explicitly convert a double format operand in an FPR to single-precision. Floating-point single-precision is enabled with four types of instruction.

1. Load Floating-Point Single

   This form of instruction accesses a single-precision operand in single format in storage, converts it to double format, and loads it into an FPR. No floating-point exceptions are caused by these instructions.
2. Round to Floating-Point Single-Precision

The Floating Round to Single-Precision instruction rounds a double-precision operand to single-precision, checking the exponent for single-precision range and handling any exceptions according to respective enable bits, and places that operand into an FPR in double format. For results produced by single-precision arithmetic instructions, single-precision loads, and other instances of the Floating Round to Single-Precision instruction, this operation does not alter the value.

3. Single-Precision Arithmetic Instructions

This form of instruction takes operands from the FPRs in double format, performs the operation as if it produced an intermediate result having infinite precision and unbounded exponent range, and then coerces this intermediate result to fit in single format. Status bits, in the FPSCR and optionally in the Condition Register, are set to reflect the single-precision result. The result is then converted to double format and placed into an FPR. The result lies in the range supported by the single format.

If any input value is not representable in single format and either OE=1 or UE=1, the result placed into the target FPR, and the setting of status bits in the FPSCR and in the Condition Register (if Rc=1), are undefined.

For fres[] or frsqrtes[], if the input value is finite and has an unbiased exponent greater than +127, the input value is interpreted as an Infinity.

4. Store Floating-Point Single

This form of instruction converts a double-precision operand to single format and stores that operand into storage. No floating-point exceptions are caused by these instructions. (The value being stored is effectively assumed to be the result of an instruction of one of the preceding three types.)

When the result of a Load Floating-Point Single, Floating Round to Single-Precision, or single-precision arithmetic instruction is stored in an FPR, the low-order 29 FRACTION bits are zero.

--- Programming Note ---

The Floating Round to Single-Precision instruction is provided to allow value conversion from double-precision to single-precision with appropriate exception checking and rounding. This instruction should be used to convert double-precision floating-point values (produced by double-precision load and arithmetic instructions and by fcfid) to single-precision values prior to storing them into single format storage elements or using them as operands for single-precision arithmetic instructions. Values produced by single-precision load and arithmetic instructions are already single-precision values and can be stored directly into single format storage elements, or used directly as operands for single-precision arithmetic instructions, without preceding the store, or the arithmetic instruction, by a Floating Round to Single-Precision instruction.

--- Programming Note ---

A single-precision value can be used in double-precision arithmetic operations. The reverse is true only if the double-precision value is representable in single format.

Some implementations may execute single-precision arithmetic instructions faster than double-precision arithmetic instructions. Therefore, if double-precision accuracy is not required, single-precision data and instructions should be used.

4.3.5.2 Integer-Valued Operands

Instructions are provided to round floating-point operands to integer values in floating-point format. To facilitate exchange of data between the floating-point and fixed-Point facilities, instructions are provided to convert between floating-point double format and fixed-point integer format in an FPR. Computation on integer-valued operands may be performed using arithmetic instructions of the required precision. (The results may not be integer values.) The two groups of instructions provided specifically to support integer-valued operands are described below.

1. Floating Round to Integer

The Floating Round to Integer instructions round a double-precision operand to an integer value in floating-point double format. These instructions may cause Invalid Operation (VXSNAN) exceptions. See Sections 4.3.6 and 4.5.1 for more information about rounding.

2. Floating Convert To/From Integer

The Floating Convert To/Integer instructions convert a double-precision operand to a 32-bit or 64-bit signed fixed-point integer format. Variants are provided both to perform rounding based on
the value of FPSCR\textsubscript{RN} and to round toward zero. These instructions may cause Invalid Operation (\texttt{VXSNAN, VXCVI}) and Inexact exceptions. The Floating Convert From Integer instruction converts a 64-bit signed fixed-point integer to a double-precision floating-point integer. Because of the limitations of the source format, only an Inexact exception may be generated.

### 4.3.6 Rounding

The material in this section applies to operations that have numeric operands (i.e., operands that are not infinities or NaNs). Rounding the intermediate result of such an operation may cause an Overflow Exception, an Underflow Exception, or an Inexact Exception. The remainder of this section assumes that the operation causes no exceptions and that the result is numeric. See Section 4.3.2, “Value Representation” and Section 4.4, “Floating-Point Exceptions” for the cases not covered here.

The Arithmetic and Rounding and Conversion instructions round their intermediate results. With the exception of the Estimate instructions, these instructions produce an intermediate result that can be regarded as having infinite precision and unbounded exponent range. All but two groups of these instructions normalize or denormalize the intermediate result prior to rounding and then place the final result into the target FPR in double format. The Floating Round to Integer and Floating Convert To Integer instructions with biased exponents ranging from 1022 through 1074 are prepared for rounding by repetitively shifting the significand right one position and incrementing the biased exponent until it reaches a value of 1075. (Intermediate results with biased exponents 1075 or larger are already integers, and with biased exponents 1021 or less round to zero.) After rounding, the final result for Floating Round to Integer is normalized and put in double format, and for Floating Convert To Integer is converted to a signed fixed-point integer.

FPSCR bits \texttt{FR} and \texttt{FI} generally indicate the results of rounding. Each of the instructions which rounds its intermediate result sets these bits. If the fraction is incremented during rounding then \texttt{FR} is set to 1, otherwise \texttt{FR} is set to 0. If the result is inexact then \texttt{FI} is set to 1, otherwise \texttt{FI} is set to zero. The Round to Integer instructions are exceptions to this rule, setting \texttt{FR} and \texttt{FI} to 0. The Estimate instructions set \texttt{FR} and \texttt{FI} to undefined values. The remaining floating-point instructions do not alter \texttt{FR} and \texttt{FI}.

Four user-selectable rounding modes are provided through the Floating-Point Rounding Control field in the FPSCR. See Section 4.2.2, “Floating-Point Status and Control Register”. These are encoded as follows.

<table>
<thead>
<tr>
<th>RN</th>
<th>Rounding Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Round to Nearest</td>
</tr>
<tr>
<td>01</td>
<td>Round toward Zero</td>
</tr>
<tr>
<td>10</td>
<td>Round toward +Infinity</td>
</tr>
<tr>
<td>11</td>
<td>Round toward -Infinity</td>
</tr>
</tbody>
</table>

Let \( Z \) be the intermediate arithmetic result or the operand of a convert operation. If \( Z \) can be represented exactly in the target format, then the result in all rounding modes is \( Z \) as represented in the target format. If \( Z \) cannot be represented exactly in the target format, let \( Z_1 \) and \( Z_2 \) bound \( Z \) as the next larger and next smaller numbers representable in the target format. Then \( Z_1 \) or \( Z_2 \) can be used to approximate the result in the target format.

Figure 52 shows the relation of \( Z, Z_1, \text{ and } Z_2 \) in this case. The following rules specify the rounding in the four modes. “LSB” means “least significant bit”.

![Figure 52. Selection of Z1 and Z2](image-url)
4.4 Floating-Point Exceptions

This architecture defines the following floating-point exceptions:

- **Invalid Operation Exception**
  - SNaN
  - Infinity–Infinity
  - Infinity–Zero
  - Zero–Zero
  - Invalid Compare
  - Software-Defined Condition
  - Invalid Square Root
  - Invalid Integer Convert
- **Zero Divide Exception**
- **Overflow Exception**
- **Underflow Exception**
- **Inexact Exception**

These exceptions, other than Invalid Operation Exception due to Software-Defined Condition, may occur during execution of computational instructions. An Invalid Operation Exception due to Software-Defined Condition occurs when a Move To FPSCR instruction sets VXSOFT to 1.

Each floating-point exception, and each category of Invalid Operation Exception, has an exception bit in the FPSCR. In addition, each floating-point exception has a corresponding enable bit in the FPSCR. The exception bit indicates occurrence of the corresponding exception. If an exception occurs, the corresponding enable bit governs the result produced by the instruction and, in conjunction with the FE0 and FE1 bits (see page 141), whether and how the system floating-point enabled exception error handler is invoked. (In general, the enabling specified by the enable bit is of invoking the system error handler, not of permitting the exception to occur. The occurrence of an exception depends only on the instruction and its inputs, not on the setting of any control bits. The only deviation from this general rule is that the occurrence of an Underflow Exception may depend on the setting of the enable bit.)

A single instruction, other than `mtfsfi` or `mtsf`, may set more than one exception bit only in the following cases:

- **Inexact Exception** may be set with **Overflow Exception**.
- **Inexact Exception** may be set with **Underflow Exception**.
- **Invalid Operation Exception** (SNaN) is set with **Invalid Operation Exception** (`-∞×0`) for **Multiply-Add** instructions for which the values being multiplied are infinity and zero and the value being added is an SNaN.
- **Invalid Operation Exception** (SNaN) may be set with **Invalid Operation Exception** (Invalid Compare) for **Compare Ordered** instructions.
- **Invalid Operation Exception** (SNaN) may be set with **Invalid Operation Exception** (Invalid Integer Convert) for **Convert To Integer** instructions.

When an exception occurs the writing of a result to the target register may be suppressed or a result may be delivered, depending on the exception.

The writing of a result to the target register is suppressed for the following kinds of exception, so that there is no possibility that one of the operands is lost:

- **Enabled Invalid Operation**
- **Enabled Zero Divide**

For the remaining kinds of exception, a result is generated and written to the destination specified by the instruction causing the exception. The result may be a different value for the enabled and disabled conditions for some of these exceptions. The kinds of exception that deliver a result are the following:

- **Disabled Invalid Operation**
- **Disabled Zero Divide**
- **Disabled Overflow**
- **Disabled Underflow**
- **Disabled Inexact**
- **Enabled Overflow**
- **Enabled Underflow**
- **Enabled Inexact**

Subsequent sections define each of the floating-point exceptions and specify the action that is taken when they are detected.

The IEEE standard specifies the handling of exceptional conditions in terms of “traps” and “trap handlers”. In this architecture, an FPSCR exception enable bit of 1 causes generation of the result value specified in the IEEE standard for the “trap enabled” case; the expectation is that the exception will be detected by software, which will revise the result. An FPSCR exception enable bit of 0 causes generation of the “default result” value specified for the “trap disabled” (or “no trap occurs” or “trap is not implemented”) case; the expectation is that the exception will not be detected by software, which will simply use the default result. The result to be delivered in each case for each exception is described in the sections below.

The IEEE default behavior when an exception occurs is to generate a default value and not to notify software. In this architecture, if the IEEE default behavior when an exception occurs is desired for all exceptions, all FPSCR exception enable bits should be set to 0 and Ignore Exceptions Mode (see below) should be used. In this case the system floating-point enabled exception error handler is not invoked, even if floating-point exceptions occur: software can inspect the FPSCR exception bits if necessary, to determine whether exceptions have occurred.

In this architecture, if software is to be notified that a given kind of exception has occurred, the corresponding FPSCR exception enable bit must be set to 1 and a mode other than Ignore Exceptions Mode must be used. In this case the system floating-point enabled exception error handler is invoked if an enabled float-
ing-point exception occurs. The system floating-point enabled exception error handler is also invoked if a Move To FPSCR instruction causes an exception bit and the corresponding enable bit both to be 1; the Move To FPSCR instruction is considered to cause the enabled exception.

The FE0 and FE1 bits control whether and how the system floating-point enabled exception error handler is invoked if an enabled floating-point exception occurs. The location of these bits and the requirements for altering them are described in Book III. (The system floating-point enabled exception error handler is never invoked because of a disabled floating-point exception.) The effects of the four possible settings of these bits are as follows.

<table>
<thead>
<tr>
<th>FE0</th>
<th>FE1</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Ignore Exceptions Mode</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Floating-point exceptions do not cause the system floating-point enabled exception error handler to be invoked.</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Imprecise Nonrecoverable Mode</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The system floating-point enabled exception error handler is invoked at some point after the instruction that caused the enabled exception. It may not be possible to identify the excepting instruction or the data that caused the exception. Results produced by the excepting instruction may have been used by or may have affected subsequent instructions that are executed before the error handler is invoked.</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Imprecise Recoverable Mode</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The system floating-point enabled exception error handler is invoked at some point at or beyond the instruction that caused the enabled exception. Sufficient information is provided to the error handler that it can identify the excepting instruction and the operands, and correct the result. No results produced by the excepting instruction have been used by or have affected subsequent instructions that are executed before the error handler is invoked.</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Precise Mode</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The system floating-point enabled exception error handler is invoked precisely at the instruction that caused the enabled exception.</td>
</tr>
</tbody>
</table>

In all cases, the question of whether a floating-point result is stored, and what value is stored, is governed by the FPSCR exception enable bits, as described in subsequent sections, and is not affected by the value of the FE0 and FE1 bits.

In all cases in which the system floating-point enabled exception error handler is invoked, all instructions before the instruction at which the system floating-point enabled exception error handler is invoked have completed, and no instruction after the instruction at which the system floating-point enabled exception error handler is invoked has begun execution. The instruction at which the system floating-point enabled exception error handler is invoked has completed if it is the excepting instruction and there is only one such instruction. Otherwise it has not begun execution (or may have been partially executed in some cases, as described in Book III).

**Programming Note**

In any of the three non-Precise modes, a Floating-Point Status and Control Register instruction can be used to force any exceptions, due to instructions initiated before the Floating-Point Status and Control Register instruction, to be recorded in the FPSCR. (This forcing is superfluous for Precise Mode.)

In either of the Imprecise modes, a Floating-Point Status and Control Register instruction can be used to force any invocations of the system floating-point enabled exception error handler, due to instructions initiated before the Floating-Point Status and Control Register instruction, to occur. (This forcing has no effect in Ignore Exceptions Mode, and is superfluous for Precise Mode.)

The last sentence of the paragraph preceding this Programming Note can apply only in the Imprecise modes, or if the mode has just been changed from Ignore Exceptions Mode to some other mode. (It always applies in the latter case.)

In order to obtain the best performance across the widest range of implementations, the programmer should obey the following guidelines.

- If the IEEE default results are acceptable to the application, Ignore Exceptions Mode should be used with all FPSCR exception enable bits set to 0.
- If the IEEE default results are not acceptable to the application, Imprecise Nonrecoverable Mode should be used, or Imprecise Recoverable Mode if recoverability is needed, with FPSCR exception enable bits set to 1 for those exceptions for which the system floating-point enabled exception error handler is to be invoked.
- Ignore Exceptions Mode should not, in general, be used when any FPSCR exception enable bits are set to 1.
- Precise Mode may degrade performance in some implementations, perhaps substantially, and therefore should be used only for debugging and other specialized applications.
4.4.1 Invalid Operation Exception

4.4.1.1 Definition
An Invalid Operation Exception occurs when an operand is invalid for the specified operation. The invalid operations are:
- Any floating-point operation on a Signaling NaN (SNaN)
- For add or subtract operations, magnitude subtraction of infinities ($\infty - \infty$)
- Division of infinity by infinity ($\infty / \infty$)
- Division of zero by zero (0/0)
- Multiplication of infinity by zero ($\infty \times 0$)
- Ordered comparison involving a NaN (Invalid Compare)
- Square root or reciprocal square root of a negative number (Invalid Square Root)
- Integer convert involving a number too large in magnitude to be represented in the target format, or involving an infinity or a NaN (Invalid Integer Convert)

An Invalid Operation Exception also occurs when an mtfsfi, mtfsf, or mtfsb1 instruction is executed that sets VXSOFT to 1 (Software-Defined Condition).

4.4.1.2 Action
The action to be taken depends on the setting of the Invalid Operation Exception Enable bit of the FPSCR.

When Invalid Operation Exception is enabled ($VE=1$) and an Invalid Operation Exception occurs, the following actions are taken:
1. One or two Invalid Operation Exceptions are set
   - VXSNAN (if SNaN)
   - VXSI (if any NaN)
   - VXDI (if $\infty - \infty$)
   - VXZDZ (if 0/0)
   - VXNZ (if $\infty \times 0$)
   - VXVC (if invalid compare)
   - VXSOFT (if software-defined condition)
   - VXSV (if invalid square root)
   - VXCV (if invalid integer convert)

2. If the operation is an arithmetic or Floating Round to Single-Precision operation, the target FPR is set to a Quiet NaN.
   - FR FI are set to zero
   - FPRF is set to indicate the class of the result (Quiet NaN)

3. If the operation is a convert to 64-bit integer operation, the target FPR is set as follows:
   - FRT is set to the most positive 64-bit integer if the operand in FRB is a positive number or $+\infty$,
   - FRT is set to the most negative 64-bit integer if the operand in FRB is a negative number, $-\infty$, or NaN.
   - FR FI are set to zero
   - FPRF is undefined

4. If the operation is a compare, FR FI C are unchanged

When Invalid Operation Exception is disabled ($VE=0$) and an Invalid Operation Exception occurs, the following actions are taken:
1. One or two Invalid Operation Exceptions are set
   - VXSNAN (if SNaN)
   - VXSI (if any NaN)
   - VXDI (if $\infty - \infty$)
   - VXZDZ (if 0/0)
   - VXNZ (if $\infty \times 0$)
   - VXVC (if invalid compare)
   - VXSOFT (if software-defined condition)
   - VXSV (if invalid square root)
   - VXCV (if invalid integer convert)

2. If the operation is an arithmetic or Floating Round to Integer operation, the target FPR is set as follows:
   - FRT is set to the most positive 64-bit integer if the operand in FRB is a positive number or $+\infty$,
   - FRT is set to the most negative 64-bit integer if the operand in FRB is a negative number, $-\infty$, or NaN.
   - FR FI are set to zero
   - FPRF is undefined

3. If the operation is a convert to 32-bit integer operation, the target FPR is set as follows:
   - FRT0:31 ← undefined
   - FRT32:63 are set to the most positive 32-bit integer if the operand in FRB is a positive number or $+\infty$,
   - FRT32:63 are set to the most negative 32-bit integer if the operand in FRB is a negative number, $-\infty$, or NaN.
   - FR FI are set to zero
   - FPRF is undefined

4. If the operation is a compare, FR FI C are unchanged

5. If the operation is a compare, FR FI C are changed

6. If an mtfsfi, mtfsf, or mtfsb1 instruction is executed that sets VXSOFT to 1, the FPSCR is set as specified in the instruction description.

4.4.2 Zero Divide Exception

4.4.2.1 Definition
A Zero Divide Exception occurs when a Divide instruction is executed with a zero divisor value and a finite nonzero dividend value. It also occurs when a Reciprocal Estimate instruction (fre[s] or frsqrte[s]) is executed with an operand value of zero.
4.4.2.2 Action

The action to be taken depends on the setting of the Zero Divide Exception Enable bit of the FPSCR.

When Zero Divide Exception is enabled (ZE=1) and a Zero Divide Exception occurs, the following actions are taken:

1. Zero Divide Exception is set
   \[ ZX \leftarrow 1 \]
2. The target FPR is unchanged
3. \( FR, FI \) are set to zero
4. \( FPRF \) is unchanged

When Zero Divide Exception is disabled (ZE=0) and a Zero Divide Exception occurs, the following actions are taken:

1. Zero Divide Exception is set
   \[ ZX \leftarrow 1 \]
2. The target FPR is set to \( \pm \)Infinity, where the sign is determined by the XOR of the signs of the operands
3. \( FR, FI \) are set to zero
4. \( FPRF \) is set to indicate the class and sign of the result (\( \pm \)Infinity)

4.4.3 Overflow Exception

4.4.3.1 Definition

An Overflow Exception occurs when the magnitude of what would have been the rounded result if the exponent range were unbounded exceeds that of the largest finite number of the specified result precision.

4.4.3.2 Action

The action to be taken depends on the setting of the Overflow Exception Enable bit of the FPSCR.

When Overflow Exception is enabled (OE=1) and an Overflow Exception occurs, the following actions are taken:

1. Overflow Exception is set
   \[ OX \leftarrow 1 \]
2. For double-precision arithmetic instructions, the exponent of the normalized intermediate result is adjusted by subtracting 1536
3. For single-precision arithmetic instructions and the Floating Round to Single-Precision instruction, the exponent of the normalized intermediate result is adjusted by subtracting 192
4. The adjusted rounded result is placed into the target FPR
5. \( FR \) is undefined
6. \( FI \) is set to 1
7. \( FPRF \) is set to indicate the class and sign of the result (\( \pm \)Infinity or \( \pm \)Normal Number)

When Overflow Exception is disabled (OE=0) and an Overflow Exception occurs, the following actions are taken:

1. Overflow Exception is set
   \[ OX \leftarrow 1 \]
2. Inexact Exception is set
   \[ XX \leftarrow 1 \]
3. The result is determined by the rounding mode (RN) and the sign of the intermediate result as follows:
   - Round to Nearest
     Store \( \pm \)Infinity, where the sign is the sign of the intermediate result
   - Round toward Zero
     Store the format’s largest finite number with the sign of the intermediate result
   - Round toward +Infinity
     For negative overflow, store the format’s most negative finite number; for positive overflow, store +Infinity
   - Round toward −Infinity
     For negative overflow, store −Infinity; for positive overflow, store the format’s largest finite number
4. The result is placed into the target FPR
5. \( FR \) is undefined
6. \( FI \) is set to 1
7. \( FPRF \) is set to indicate the class and sign of the result (\( \pm \)Infinity or \( \pm \)Normal Number)
4.4.4 Underflow Exception

4.4.4.1 Definition

Underflow Exception is defined separately for the enabled and disabled states:

- **Enabled:**
  Underflow occurs when the intermediate result is “Tiny”.

- **Disabled:**
  Underflow occurs when the intermediate result is “Tiny” and there is “Loss of Accuracy”.

A “Tiny” result is detected before rounding, when a non-zero intermediate result computed as though both the precision and the exponent range were unbounded would be less in magnitude than the smallest normalized number.

If the intermediate result is “Tiny” and Underflow Exception is disabled (\(UE=0\)) then the intermediate result is denormalized (see Section 4.3.4, “Normalization and Denormalization” on page 137) and rounded (see Section 4.3.6, “Rounding” on page 139) before being placed into the target FPR.

“Loss of Accuracy” is detected when the delivered result value differs from what would have been computed were both the precision and the exponent range unbounded.

4.4.4.2 Action

The action to be taken depends on the setting of the Underflow Exception Enable bit of the FPSCR.

When Underflow Exception is enabled (\(UE=1\)) and an Underflow Exception occurs, the following actions are taken:

1. Underflow Exception is set
   \[UX \leftarrow 1\]
2. For double-precision arithmetic instructions, the exponent of the normalized intermediate result is adjusted by adding 1536
3. For single-precision arithmetic instructions and the Floating Round to Single-Precision instruction, the exponent of the normalized intermediate result is adjusted by adding 192
4. The adjusted rounded result is placed into the target FPR
5. \(FPRF\) is set to indicate the class and sign of the result (± Normalized Number)

When Underflow Exception is disabled (\(UE=0\)) and an Underflow Exception occurs, the following actions are taken:

1. Underflow Exception is set
   \[UX \leftarrow 1\]
2. The rounded result is placed into the target FPR
3. \(FPRF\) is set to indicate the class and sign of the result (± Normalized Number, ± Denormalized Number, or ± Zero)

4.4.5 Inexact Exception

4.4.5.1 Definition

An Inexact Exception occurs when one of two conditions occur during rounding:

1. The rounded result differs from the intermediate result assuming both the precision and the exponent range of the intermediate result to be unbounded. In this case the result is said to be inexact. (If the rounding causes an enabled Overflow Exception or an enabled Underflow Exception, an Inexact Exception also occurs only if the significands of the rounded result and the intermediate result differ.)
2. The rounded result overflows and Overflow Exception is disabled.

4.4.5.2 Action

The action to be taken does not depend on the setting of the Inexact Exception Enable bit of the FPSCR.

When an Inexact Exception occurs, the following actions are taken:

1. Inexact Exception is set
   \[XX \leftarrow 1\]
2. The rounded or overflowed result is placed into the target FPR
3. \(FPRF\) is set to indicate the class and sign of the result

Programming Note

The FR and FI bits are provided to allow the system floating-point enabled exception error handler, when invoked because of an Underflow Exception, to simulate a “trap disabled” environment. That is, the FR and FI bits allow the system floating-point enabled exception error handler to unround the result, thus allowing the result to be denormalized.

In some implementations, enabling Inexact Exceptions may degrade performance more than does enabling other types of floating-point exception.
4.5 Floating-Point Execution Models

All implementations of this architecture must provide the equivalent of the following execution models to ensure that identical results are obtained.

Special rules are provided in the definition of the computational instructions for the infinities, denormalized numbers and NaNs. The material in the remainder of this section applies to instructions that have numeric operands and a numeric result (i.e., operands and result that are not infinities or NaNs), and that cause no exceptions. See Section 4.3.2 and Section 4.4 for the cases not covered here.

Although the double format specifies an 11-bit exponent, exponent arithmetic makes use of two additional bits to avoid potential transient overflow conditions. One extra bit is required when denormalized double-precision numbers are prenormalized. The second bit is required to permit the computation of the adjusted exponent value in the following cases when the corresponding exception enable bit is 1:

• Underflow during multiplication using a denormalized operand.
• Overflow during division using a denormalized divisor.

The IEEE standard includes 32-bit and 64-bit arithmetic. The standard requires that single-precision arithmetic be provided for single-precision operands. The standard permits double-precision floating-point operations to have either (or both) single-precision or double-precision operands, but states that single-precision floating-point operations should not accept double-precision operands. The Power ISA follows these guidelines; double-precision arithmetic instructions can have operands of either or both precisions, while single-precision arithmetic instructions require all operands to be single-precision. Double-precision arithmetic instructions and \texttt{fcfidd} produce double-precision values, while single-precision arithmetic instructions produce single-precision values.

For arithmetic instructions, conversions from double-precision to single-precision must be done explicitly by software, while conversions from single-precision to double-precision are done implicitly.

4.5.1 Execution Model for IEEE Operations

The following description uses 64-bit arithmetic as an example. 32-bit arithmetic is similar except that the \texttt{FRACTION} is a 23-bit field, and the single-precision Guard, Round, and Sticky bits (described in this section) are logically adjacent to the 23-bit \texttt{FRACTION} field.

IEEE-conforming significand arithmetic is considered to be performed with a floating-point accumulator having the following format, where bits 0:55 comprise the significand of the intermediate result.

\[
\begin{array}{cccc}
S & C & L & \text{FRACTION} & G & R & X \\
0 & 1 & & 53 & 54 & 55 \\
\end{array}
\]

Figure 53. IEEE 64-bit execution model

The S bit is the sign bit.

The C bit is the carry bit, which captures the carry out of the significand.

The L bit is the leading unit bit of the significand, which receives the implicit bit from the operand.

The \texttt{FRACTION} is a 52-bit field that accepts the fraction of the operand.

The Guard (G), Round (R), and Sticky (X) bits are extensions to the low-order bits of the accumulator. The G and R bits are required for postnormalization of the result. The G, R, and X bits are required during rounding to determine if the intermediate result is equally near the two nearest representable values. The X bit serves as an extension to the G and R bits by representing the logical OR of all bits that may appear to the low-order side of the \texttt{R} bit, due either to shifting the accumulator right or to other generation of low-order result bits. The G and \texttt{R} bits participate in the left shifts with zeros being shifted into the \texttt{R} bit. Figure 54 shows the significance of the G, R, and X bits with respect to the intermediate result (IR), the representable number next lower in magnitude (NL), and the representable number next higher in magnitude (NH).

\[
\begin{array}{cccc}
G & R & X & \text{Interpretation} \\
0 & 0 & 0 & \text{IR is exact} \\
0 & 0 & 1 & \text{IR closer to NL} \\
0 & 1 & 0 & \text{IR midway between NL and NH} \\
0 & 1 & 1 & \\
1 & 0 & 0 & \text{IR closer to NH} \\
1 & 0 & 1 & \\
1 & 1 & 0 & \\
1 & 1 & 1 & \\
\end{array}
\]

Figure 54. Interpretation of G, R, and X bits

For arithmetic instructions, conversions from double-precision to single-precision must be done explicitly by software, while conversions from single-precision to double-precision are done implicitly.
The significand of the intermediate result is prepared for rounding by shifting its contents right, if required, until the least significant bit to be retained is in the low-order bit position of the fraction. Four user-selectable rounding modes are provided through RN as described in Section 4.3.6, “Rounding” on page 139. Using Z1 and Z2 as defined on page 139, the rules for rounding in each mode are as follows.

- **Round to Nearest**
  
  **Guard bit = 0**
  The result is truncated. (Result exact (GRX=000) or closest to next lower value in magnitude (GRX=001, 010, or 011))

  **Guard bit = 1**
  Depends on Round and Sticky bits:

  **Case a**
  If the Round or Sticky bit is 1 (inclusive), the result is incremented. (Result closest to next higher value in magnitude (GRX=101, 110, or 111))

  **Case b**
  If the Round and Sticky bits are 0 (result midway between closest representable values), then if the low-order bit of the result is 1 the result is incremented. Otherwise (the low-order bit of the result is 0) the result is truncated (this is the case of a tie rounded to even).

- **Round toward Zero**
  Choose the smaller in magnitude of Z1 or Z2. If the Guard, Round, or Sticky bit is nonzero, the result is inexact.

- **Round toward + Infinity**
  Choose Z1.

- **Round toward - Infinity**
  Choose Z2.

If rounding results in a carry into C, the significand is shifted right one position and the exponent is incremented by one. This yields an inexact result, and possibly also exponent overflow. If any of the Guard, Round, or Sticky bits is nonzero, then the result is also inexact. Fraction bits are stored to the target FPR. For Floating Round to Integer, Floating Round to Single-Precision, and single-precision arithmetic instructions, low-order zeros must be appended as appropriate to fill out the double-precision fraction.
4.5.2 Execution Model for Multiply-Add Type Instructions

The Power ISA provides a special form of instruction that performs up to three operations in one instruction (a multiplication, an addition, and a negation). With this added capability comes the special ability to produce a more exact intermediate result as input to the rounder. 32-bit arithmetic is similar except that the \texttt{FRACTION} field is smaller.

Multiply-add significand arithmetic is considered to be performed with a floating-point accumulator having the following format, where bits 0:106 comprise the significand of the intermediate result.

\begin{figure}[h]
\centering
\begin{tabular}{cccc}
S & C & L & FRACTION \hline
0 & 1 & 2 & 3 & \multicolumn{1}{c}{106}
\end{tabular}
\caption{Multiply-add 64-bit execution model}
\end{figure}

The first part of the operation is a multiplication. The multiplication has two 53-bit significands as inputs, which are assumed to be prenormalized, and produces a result conforming to the above model. If there is a carry out of the significand (into the C bit), then the significand is shifted right one position, shifting the L bit (leading unit bit) into the most significant bit of the \texttt{FRACTION} and shifting the C bit (carry out) into the L bit. All 106 bits (L bit, the \texttt{FRACTION}) of the product take part in the add operation. If the exponents of the two inputs to the adder are not equal, the significand of the operand with the smaller exponent is aligned (shifted) to the right by an amount that is added to that exponent to make it equal to the other input’s exponent. Zeros are shifted into the left of the significand as it is aligned and bits shifted out of bit 105 of the significand are ORed into the X’ bit. The add operation also produces a result conforming to the above model with the X’ bit taking part in the add operation.

The result of the addition is then normalized, with all bits of the addition result, except the X’ bit, participating in the shift. The normalized result serves as the intermediate result that is input to the rounder.

For rounding, the conceptual Guard, Round, and Sticky bits are defined in terms of accumulator bits. Figure 57 shows the positions of the Guard, Round, and Sticky bits for double-precision and single-precision floating-point numbers in the multiply-add execution model.

\begin{figure}[h]
\centering
\begin{tabular}{|c|c|c|c|}
\hline
\textbf{Format} & \textbf{Guard} & \textbf{Round} & \textbf{Sticky} \\
\hline
Double & 53 & 54 & OR of 55:105, X’ \\
Single & 24 & 25 & OR of 26:105, X’ \\
\hline
\end{tabular}
\caption{Location of the Guard, Round, and Sticky bits in the multiply-add execution model}
\end{figure}

The rules for rounding the intermediate result are the same as those given in Section 4.5.1.

If the instruction is \textit{Floating Negative Multiply-Add} or \textit{Floating Negative Multiply-Subtract}, the final result is negated.
4.6 Floating-Point Facility Instructions

4.6.1 Floating-Point Storage Access Instructions

The Storage Access instructions compute the effective address (EA) of the storage to be accessed as described in Section 1.10.3, “Effective Address Calculation” on page 29.

Programming Note

The la extended mnemonic permits computing an effective address as a Load or Store instruction would, but loads the address itself into a GPR rather than loading the value that is in storage at that address. This extended mnemonic is described in Section C.10, “Miscellaneous Mnenomics” on page 1022.

4.6.1.1 Storage Access Exceptions

Storage accesses will cause the system data storage error handler to be invoked if the program is not allowed to modify the target storage (Store only), or if the program attempts to access storage that is unavailable.
4.6.2 Floating-Point Load Instructions

There are three basic forms of load instruction: single-precision, double-precision, and integer. The integer form is provided by the Load Floating-Point as Integer Word Algebraic instruction, described on page 153. Because the FPRs support only floating-point double format, single-precision Load Floating-Point instructions convert single-precision data to double format prior to loading the operand into the target FPR. The conversion and loading steps are as follows.

Let \( \text{WORD}_{0..31} \) be the floating-point single-precision operand accessed from storage.

**Normalized Operand**

\[
\text{if } \text{WORD}_{0..8} > 0 \text{ and } \text{WORD}_{0..8} < 255 \text{ then}
\]
\[
\begin{align*}
\text{FRT}_0 : 1 & \leftarrow \text{WORD}_0 : 1 \\
\text{FRT}_2 & \leftarrow \neg \text{WORD}_0 \\
\text{FRT}_3 & \leftarrow \neg \text{WORD}_0 \\
\text{FRT}_4 & \leftarrow \neg \text{WORD}_0 \\
\text{FRT}_5 : 63 & \leftarrow \text{WORD}_2 : 31 \| \text{290}
\end{align*}
\]

**Denormalized Operand**

\[
\text{if } \text{WORD}_{0..8} = 0 \text{ and } \text{WORD}_{0..31} \neq 0 \text{ then}
\]
\[
\begin{align*}
\text{sign} & \leftarrow \text{WORD}_0 \\
\text{exp} & \leftarrow -126 \\
\text{frac}_0 : 52 & \leftarrow 0b0 \| \text{WORD}_0 : 31 \| \text{290} \\
\text{normalize the operand} \\
\text{do while } \text{frac}_0 = 0 \\
\text{frac}_0 : 52 & \leftarrow \text{frac}_1 : 52 \| 0b0 \\
\text{exp} & \leftarrow \text{exp} - 1 \\
\text{FRT}_0 & \leftarrow \text{sign} \\
\text{FRT}_1 : 11 & \leftarrow \text{exp} + 1023 \\
\text{FRT}_2 : 63 & \leftarrow \text{frac}_1 : 52
\end{align*}
\]

**Zero / Infinity / NaN**

\[
\text{if } \text{WORD}_{0..8} = 255 \text{ or } \text{WORD}_{0..31} = 0 \text{ then}
\]
\[
\begin{align*}
\text{FRT}_0 : 1 & \leftarrow \text{WORD}_0 : 1 \\
\text{FRT}_2 & \leftarrow \text{WORD}_0 \\
\text{FRT}_3 & \leftarrow \text{WORD}_0 \\
\text{FRT}_4 & \leftarrow \text{WORD}_0 \\
\text{FRT}_5 : 63 & \leftarrow \text{WORD}_0 : 31 \| \text{290}
\end{align*}
\]

For double-precision Load Floating-Point instructions and for the Load Floating-Point as Integer Word Algebraic instruction no conversion is required, as the data from storage are copied directly into the FPR.

Many of the Load Floating-Point instructions have an “update” form, in which register RA is updated with the effective address. For these forms, if RA≠0, the effective address is placed into register RA and the storage element (word or doubleword) addressed by EA is loaded into FRT.

**Note:** Recall that RA and RB denote General Purpose Registers, while FRT denotes a Floating-Point Register.
Load Floating-Point Single D-form

\[ \text{lfs FRT,D(RA)} \]

<table>
<thead>
<tr>
<th>48</th>
<th>FRT</th>
<th>RA</th>
<th>D</th>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>----</td>
</tr>
</tbody>
</table>

Prefixed Load Floating-Point Single

\[ \text{MLS:D-form} \]

\[ \text{plfs FRT,D(RA),R} \]

Prefix:

<table>
<thead>
<tr>
<th>1</th>
<th>2</th>
<th>0</th>
<th>0</th>
<th>d0</th>
<th>14</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>6</td>
<td>6</td>
<td>6</td>
<td>12</td>
<td>31</td>
</tr>
</tbody>
</table>

Suffix:

<table>
<thead>
<tr>
<th>48</th>
<th>FRT</th>
<th>RA</th>
<th>D</th>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>----</td>
</tr>
</tbody>
</table>

if "lfs" then
\[ \text{EA} \leftarrow (\text{RA}|0) + \text{EXTS64(D)} \]
if "plfs" & R=0 then
\[ \text{EA} \leftarrow (\text{RA}|0) + \text{EXTS64}(d0|d1) \]
if "plfs" & R=1 then
\[ \text{EA} \leftarrow (\text{CIA} + \text{EXTS64}(d0|d1)) \]
\[ \text{FRT} \leftarrow \text{DOUBLE(MEM(EA, 4))} \]

For \text{lfs}, let the effective address (EA) be the sum of the contents of register RA, or the value 0 if RA=0, and the value D, sign-extended to 64 bits.

For \text{plfs} with R=0, let the effective address (EA) be the sum of the contents of register RA, or the value 0 if RA=0, and the value d0|d1, sign-extended to 64 bits.

For \text{plfs} with R=1, let the effective address (EA) be the sum of the address of the instruction and the value d0|d1, sign-extended to 64 bits.

The word in storage addressed by EA is interpreted as a floating-point single-precision operand. This word is converted to floating-point double format (see page 149) and placed into register FRT.

**Special Registers Altered:**
None

Extended mnemonics for Prefixes Load Floating-Point Single:

4.6.3 Floating-Point Store Instructions

There are three basic forms of store instruction: single-precision, double-precision, and integer. The integer form is provided by the Store Floating-Point as Integer Word instruction, described on page 158. Because the FPRs support only floating-point double format for floating-point data, single-precision Store Floating-Point instructions convert double-precision data to single format prior to storing the operand into storage. The conversion steps are as follows.

Let $\text{WORD}_{0:31}$ be the word in storage written to.

**No Denormalization Required (includes Zero / Infinity / NaN)**

\[
\text{if } \text{FRS}_1:13 > \text{BBB} \text{ or } \text{FRS}_1:63 = 0 \text{ then}
\]
\[
\text{WORD}_{0:1} \leftarrow \text{FRS}_0:1
\]
\[
\text{WORD}_{2:31} \leftarrow \text{FRS}_5:34
\]

**Denormalization Required**

\[
\text{if } 874 \leq \text{FRS}_1:11 \leq \text{BBB} \text{ then}
\]
\[
\text{sign} \leftarrow \text{FRS}_0
\]
\[
\text{exp} \leftarrow \text{FRS}_1:11 - 1023
\]
\[
\text{frac}_{0:52} \leftarrow 0b1 || \text{FRS}_{0:63}
\]
\[
\text{denormalize operand}
\]
\[
\text{do while } \text{exp} < -126
\]
\[
\text{frac}_{0:51} \leftarrow 0b0 || \text{frac}_{0:51}
\]
\[
\text{exp} \leftarrow \text{exp} + 1
\]
\[
\text{WORD}_{0} \leftarrow \text{sign}
\]
\[
\text{WORD}_{2:8} \leftarrow 0x00
\]
\[
\text{WORD}_{9:31} \leftarrow \text{frac}_{1:23}
\]
\[
\text{else } \text{WORD} \leftarrow \text{undefined}
\]

Notice that if the value to be stored by a single-precision Store Floating-Point instruction is larger in magnitude than the maximum number representable in single format, the first case above (No Denormalization Required) applies. The result stored in WORD is then a well-defined value, but is not numerically equal to the value in the source register (i.e., the result of a single-precision Load Floating-Point from WORD will not compare equal to the contents of the original source register).

For double-precision Store Floating-Point instructions and for the Store Floating-Point as Integer Word instruction no conversion is required, as the data from the FPR are copied directly into storage.

Many of the Store Floating-Point instructions have an “update” form, in which register RA is updated with the effective address. For these forms, if RA≠0, the effective address is placed into register RA.

**Note:** Recall that RA and RB denote General Purpose Registers, while FRS denotes a Floating-Point Register.
Store Floating-Point Single D-form

\[
\begin{array}{cccc}
\text{stfs} & \text{FRS, D(RA)} \\
52 & 6 & 11 & 16 & D \\
0 & & & & 31
\end{array}
\]

**Prefixed Store Floating-Point Single MLS:D-form**

\[
\begin{array}{cccc}
\text{pstfs} & \text{FRS, D(RA), R} \\
52 & 6 & 11 & 16 & d1 \\
0 & & & & 31
\end{array}
\]

\[
\text{if } \text{"stfs" then} \\
\text{EA} \leftarrow (\text{RA}|0) + \text{EXTS}(D) \\
\text{if } \text{"pstfs" & R=0 then} \\
\text{EA} \leftarrow (\text{RA}|0) + \text{EXTS}(d0|d1) \\
\text{if } \text{"pstfs" & R=1 then} \\
\text{EA} \leftarrow \text{CIA} + \text{EXTS}(d0|d1) \\
\text{MEM(EA, 4)} \leftarrow \text{SINGLE}(\text{FRS})
\]

For **stfs**, let the effective address (EA) be the sum of the contents of register RA, or the value 0 if RA=0, and the value D, sign-extended to 64 bits.

For **pstfs** with R=0, let the effective address (EA) be the sum of the contents of register RA, or the value 0 if RA=0, and the value d0|d1, sign-extended to 64 bits.

For **pstfs** with R=1, let the effective address (EA) be the sum of the address of the instruction and the value d0|d1, sign-extended to 64 bits.

The contents of register FRS are converted to single format (see page 154) and stored into the word in storage addressed by EA.

**Special Registers Altered:** None

**Extended mnemonics for Prefixed Store Floating-Point Single:**

- \text{pstfs} Fx, value(Ry)
- \text{pstfs} Fx, value

**Store Floating-Point Single Indexed X-form**

\[
\begin{array}{cccc}
\text{stfsx} & \text{FRS, RA, RB} \\
53 & 6 & 11 & 16 & D \\
0 & & & & 31
\end{array}
\]

\[
\text{if } \text{RA} = 0 \text{ then } b \leftarrow 0 \\

4.6.5 Floating-Point Move Instructions

These instructions copy data from one floating-point register to another, altering the sign bit (bit 0) as described below for `fneg`, `fabs`, `fnabs`, and `fcpsgn`. These instructions treat NaNs just like any other kind of value (e.g., the sign bit of a NaN may be altered by `fneg`, `fabs`, `fnabs`, and `fcpsgn`). These instructions do not alter the FPSCR.

**Floating Move Register X-form**

<table>

</tbody>
</table>

The contents of register `FRB` with bit 0 set to the value of bit 0 of register `FRA` are placed into register `FRT`.

Special Registers Altered:

- CR1 (if Rc=1)
Floating Merge Even Word X-form

```
fmrgew FRT,FRA,FRB

if MSR.FP=0 then FP_Unavailable()
FPR[FRT].word[0] ← FPR[FRA].word[0]
FPR[FRT].word[1] ← FPR[FRB].word[0]
```

The contents of word element 0 of FPR[FRA] are placed into word element 0 of FPR[FRT].

The contents of word element 0 of FPR[FRB] are placed into word element 1 of FPR[FRT].

*fmrgew* is treated as a *Floating-Point* instruction in terms of resource availability.

**Special Registers Altered**

None

Floating Merge Odd Word X-form

```
fmrgow FRT,FRA,FRB

if MSR.FP=0 then FP_Unavailable()
FPR[FRT].word[0] ← FPR[FRA].word[1]
```

The contents of word element 1 of FPR[FRA] are placed into word element 0 of FPR[FRT].

The contents of word element 1 of FPR[FRB] are placed into word element 1 of FPR[FRT].

*fmrgow* is treated as a *Floating-Point* instruction in terms of resource availability.

**Special Registers Altered**

None
4.6.6 Floating-Point Arithmetic Instructions

4.6.6.1 Floating-Point Elementary Arithmetic Instructions

**Floating Add A-form**

```
fadd    FRT,FRA,FRB  (Rc=0)  
fadd.   FRT,FRA,FRB  (Rc=1)
```

The floating-point operand in register `FRA` is added to the floating-point operand in register `FRB`.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of `RN` and placed into register `FRT`.

Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (`G`, `R`, and `X`) enter into the computation.

If a carry occurs, the sum’s significand is shifted right one bit position and the exponent is increased by one.

**Floating Subtract A-form**

```
fsub    FRT,FRA,FRB  (Rc=0)  
fsub.   FRT,FRA,FRB  (Rc=1)
```

The floating-point operand in register `FRB` is subtracted from the floating-point operand in register `FRA`.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of `RN` and placed into register `FRT`.

The execution of the Floating Subtract instruction is identical to that of Floating Add, except that the contents of `FRB` participate in the operation with the sign bit (bit 0) inverted.

**Special Registers Altered:**

- `FPFR` is set to the class and sign of the result, except for Invalid Operation Exceptions when `VE=1`.
- `CR1` (if `Rc=1`)

**Floating Add Single A-form**

```
fadds   FRT,FRA,FRB  (Rc=0)  
fadds.  FRT,FRA,FRB  (Rc=1)
```

**Floating Subtract Single A-form**

```
fsubs   FRT,FRA,FRB  (Rc=0)  
fsubs.  FRT,FRA,FRB  (Rc=1)
```

**Special Registers Altered:**

- `FPFR` is set to the class and sign of the result, except for Invalid Operation Exceptions when `VE=1`.
- `CR1` (if `Rc=1`)

<table>
<thead>
<tr>
<th>63</th>
<th>6</th>

(If `Rc=1`)
### Floating Multiply A-form

\[
\begin{array}{llllllll}
\text{fmul} & \text{FRT,FRA,FRC} & (Rc=0) \\
\text{fmul.} & \text{FRT,FRA,FRC} & (Rc=1) \\
\end{array}
\]

The floating-point operand in register \( \text{FRA} \) is multiplied by the floating-point operand in register \( \text{FRC} \).

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of \( RN \) and placed into register \( \text{FRT} \).

Floating-point multiplication is based on exponent addition and multiplication of the significands.

\( \text{FPRF} \) is set to the class and sign of the result, except for Invalid Operation Exceptions when \( \text{VE}=1 \).

**Special Registers Altered:**

\[
\begin{array}{llll}
\text{FPRF} & \text{FR} & \text{FI} \\
\text{FX} & \text{OX} & \text{UX} & \text{XX} \\
\text{VXSNAN} & \text{VXIMZ} \\
\text{CR1} & (\text{if Rc=1}) \\
\end{array}
\]

### Floating Divide A-form

\[
\begin{array}{llllllll}
\text{fdiv} & \text{FRT,FRA,FRB} & (Rc=0) \\
\text{fdiv.} & \text{FRT,FRA,FRB} & (Rc=1) \\
\end{array}
\]

The floating-point operand in register \( \text{FRA} \) is divided by the floating-point operand in register \( \text{FRB} \). The remainder is not supplied as a result.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of \( RN \) and placed into register \( \text{FRT} \).

Floating-point division is based on exponent subtraction and division of the significands.

\( \text{FPRF} \) is set to the class and sign of the result, except for Invalid Operation Exceptions when \( \text{VE}=1 \) and Zero Divide Exceptions when \( \text{ZE}=1 \).

**Special Registers Altered:**

\[
\begin{array}{llll}
\text{FPRF} & \text{FR} & \text{FI} \\
\text{FX} & \text{OX} & \text{UX} & \text{ZX} & \text{XX} \\
\text{VXSNAN} & \text{VXIDI} & \text{VXZDZ} \\
\text{CR1} & (\text{if Rc=1}) \\
\end{array}
\]
Floating Square Root A-form

\[
\text{fsqrt} \quad \text{FRT,FRB} \quad (Rc=0) \\
\text{fsqrt} \cdot \quad \text{FRT,FRB} \quad (Rc=1)
\]

Floating Square Root Single A-form

\[
\text{fsqrts} \quad \text{FRT,FRB} \quad (Rc=0) \\
\text{fsqrts} \cdot \quad \text{FRT,FRB} \quad (Rc=1)
\]

The square root of the floating-point operand in register \( FRB \) is placed into register \( FRT \).

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of \( RN \) and placed into register \( FRT \).

Operation with various special values of the operand is summarized below.

<table>
<thead>
<tr>
<th>Operand</th>
<th>Result</th>
<th>Exception</th>
</tr>
</thead>
<tbody>
<tr>
<td>(-\infty)</td>
<td>QNaN(^1)</td>
<td>VXSQRT</td>
</tr>
<tr>
<td>(&lt; 0)</td>

<td>QNaN</td>
<td>None</td>
</tr>
</tbody>
</table>

\(^1\) No result if \( VE=1 \)

FPSCR\(_{FFP} \) is set to the class and sign of the result, except for Invalid Operation Exceptions when FPSCR\(_{VE} = 1 \).

Special Registers Altered:

FPFR F R FI FX OX UX XX
VXSQRT VXSQRT
CR1 (if \( Rc=1 \))

Floating Reciprocal Estimate A-form

\[
\text{fre} \quad \text{FRT,FRB} \quad (Rc=0) \\
\text{fre} \cdot \quad \text{FRT,FRB} \quad (Rc=1)
\]

Floating Reciprocal Estimate Single A-form

\[
\text{fres} \quad \text{FRT,FRB} \quad (Rc=0) \\
\text{fres} \cdot \quad \text{FRT,FRB} \quad (Rc=1)
\]

An estimate of the reciprocal of the floating-point operand in register \( FRB \) is placed into register \( FRT \). Unless the reciprocal would be a zero, an infinity, the result of a trap-disabled Overflow exception, or a QNaN, the estimate is correct to a precision of one part in 256 of the reciprocal of \( (FRB) \), i.e.,

\[
\text{ABS} \left( \frac{\text{estimate} - 1/x}{1/x} \right) \leq \frac{1}{256}
\]

where \( x \) is the initial value in \( FRB \).

Operation with various special values of the operand is summarized below.

<table>
<thead>
<tr>
<th>Operand</th>
<th>Result</th>
<th>Exception</th>

\(^2\) No result if \( VE=1 \).

FPFR is set to the class and sign of the result, except for Invalid Operation Exceptions when \( VE=1 \) and Zero Divide Exceptions when \( ZE=1 \).

The results of executing this instruction may vary between implementations, and between different executions on the same implementation.

Special Registers Altered:

FPFR F R (undefined) F I (undefined)
FX OX UX ZK XX (undefined)
VXSQNAN
CR1 (if \( Rc=1 \))

Programming Note

For the Floating-Point Estimate instructions, some implementations might implement a precision higher than the minimum architected precision. Thus, a program may take advantage of the higher precision instructions to increase performance by decreasing the iterations needed for software emulation of floating-point instructions. However, there is no guarantee given about the precision which may vary (up or down) between implementations. Only programs targeted at a specific implementation (i.e., the program will not be migrated to another implementation) should take advantage of the higher precision of the instructions. All other programs should rely on the minimum architected precision, which will guarantee the program to run properly across different implementations.
**Floating Reciprocal Square Root Estimate A-form**

frsqrte FRT,FRB (Rc=0)
frsqrte FRT,FRB (Rc=1)

A estimate of the reciprocal of the square root of the floating-point operand in register \( FRB \) is placed into register \( FRT \). The estimate placed into register \( FRT \) is correct to a precision of one part in 32 of the reciprocal of \( \sqrt{FRB} \), i.e.,

\[
\text{ABS} \left( \frac{1}{\sqrt{x}} - \frac{1}{\sqrt{x}} \right) \leq \frac{1}{32}
\]

where \( x \) is the initial value in \( FRB \).

Operation with various special values of the operand is summarized below.

<table>
<thead>
<tr>
<th>Operand</th>
<th>Result</th>
<th>Exception</th>

**Floating Test for software Divide X-form**

\( \text{ftdiv BF,FRA,FRB} \)

Let \( e_a \) be the unbiased exponent of the double-precision floating-point operand in register \( FRA \).

Let \( e_b \) be the unbiased exponent of the double-precision floating-point operand in register \( FRB \).

\( fe \_\text{flag} \) is set to 1 if any of the following conditions occurs.

- The double-precision floating-point operand in register \( FRA \) is a NaN or an Infinity.
- The double-precision floating-point operand in register \( FRB \) is a Zero, a NaN, or an Infinity.
- \( e_b \) is less than or equal to \(-1022\).
- \( e_b \) is greater than or equal to \(1021\).
- The double-precision floating-point operand in register \( FRA \) is not a zero and the difference, \( e_a - e_b \), is greater than or equal to \(1023\).
- The double-precision floating-point operand in register \( FRA \) is not a zero and the difference, \( e_a - e_b \), is less than or equal to \(-1021\).
- The double-precision floating-point operand in register \( FRA \) is not a zero and \( e_a \) is less than or equal to \(-970\).

Otherwise \( fe \_\text{flag} \) is set to 0.

\( fg \_\text{flag} \) is set to 1 if either of the following conditions occurs.

- The double-precision floating-point operand in register \( FRA \) is an Infinity.
- The double-precision floating-point operand in register \( FRB \) is a Zero, an Infinity, or a denormalized value.

Otherwise \( fg \_\text{flag} \) is set to 0.

If the implementation guarantees a relative error of \( fre[s] \) of less than or equal to \(2^{-14} \), then \( fl \_\text{flag} \) is set to 1. Otherwise \( fl \_\text{flag} \) is set to 0.

**CR field BF** is set to the value \( \text{fl}_\_\text{flag} || \text{fg}_\_\text{flag} || \text{fe}_\_\text{flag} || 0b0 \).

Let \( e_b \) be the unbiased exponent of the double-precision floating-point operand in register \( FRB \).

\( fe\_flag \) is set to 1 if either of the following conditions occurs.

- The double-precision floating-point operand in register \( FRB \) is a zero, a NaN, or an infinity, or a negative value.
- \( e_b \) is less than or equal to \(-970\).

Otherwise \( fe\_flag \) is set to 0.

\( fg\_flag \) is set to 1 if the following condition occurs.

- The double-precision floating-point operand in register \( FRB \) is a Zero, an Infinity, or a denormalized value.

Otherwise \( fg\_flag \) is set to 0.

If the implementation guarantees a relative error of \( frsqrte[\text{s}][\text{u}] \) of less than or equal to \( 2^{-14} \), then \( fl\_flag \) is set to 1. Otherwise \( fl\_flag \) is set to 0.

CR field BF is set to the value \( fl\_flag \| fg\_flag \| fe\_flag \| 0b0 \).

Special Registers Altered:
CR field BF

Programming Note

\texttt{ftdiv} and \texttt{ftsqrt} are provided to accelerate software emulation of divide and square root operations, by performing the requisite special case checking. Software needs only a single branch, on FE=1 (in CR[BF]), to a special case handler. FG and FL may provide further acceleration opportunities.
4.6.6.2 Floating-Point Multiply-Add Instructions

These instructions combine a multiply and an add operation without an intermediate rounding operation. The fraction part of the intermediate product is 106 bits wide (L bit, FRACTION), and all 106 bits take part in the add/subtract portion of the instruction.

Status bits are set as follows.

- Overflow, Underflow, and Inexact Exception bits, the FR and FI bits, and the FPRF field are set based on the final result of the operation, and not on the result of the multiplication.
- Invalid Operation Exception bits are set as if the multiplication and the addition were performed using two separate instructions (fmul[s], followed by fadd[s] or fsub[s]). That is, multiplication of infinity by 0 or of anything by an SNaN, and/or addition of an SNaN, cause the corresponding exception bits to be set.

Floating Multiply-Add A-form

| fmadd | FRT,FRA,FRC,FRB  | (Rc=0) |
| fmadd. | FRT,FRA,FRC,FRB  | (Rc=1) |
| 63 | FRT | FRA | FRB | FRC | 29 | % |
| 0 | 6 | 11 | 16 | 21 | 35 | 31 |

The operation

\[ FRT ← [(FRA)´(FRC)] + (FRB) \]

is performed.

The floating-point operand in register FRA is multiplied by the floating-point operand in register FRC. The floating-point operand in register FRB is added to this intermediate result.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of RN and placed into register FRT.

FPRF is set to the class and sign of the result, except for Invalid Operation Exceptions when VE=1.

Special Registers Altered:

| FPRF | FR | FI |
| FX | OX | UX | XX |
| VXSNaN | VXISI | VXIMZ |
CR1 (if Rc=1)

Floating Multiply-Add Single A-form

| fmadds | FRT,FRA,FRC,FRB  | (Rc=0) |
| fmadds. | FRT,FRA,FRC,FRB  | (Rc=1) |
| 59 | FRT | FRA | FRB | FRC | 29 | % |
| 0 | 6 | 11 | 16 | 21 | 35 | 31 |

The operation

\[ FRT ← [(FRA)´(FRC)] + (FRB) \]

is performed.

The floating-point operand in register FRA is multiplied by the floating-point operand in register FRC. The floating-point operand in register FRB is added to this intermediate result.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of RN and placed into register FRT.

FPRF is set to the class and sign of the result, except for Invalid Operation Exceptions when VE=1.

Special Registers Altered:

| FPRF | FR | FI |
| FX | OX | UX | XX |
| VXSNaN | VXISI | VXIMZ |
CR1 (if Rc=1)

Floating Multiply-Subtract A-form

| fmsub | FRT,FRA,FRC,FRB  | (Rc=0) |
| fmsub. | FRT,FRA,FRC,FRB  | (Rc=1) |
| 63 | FRT | FRA | FRB | FRC | 28 | % |
| 0 | 6 | 11 | 16 | 21 | 35 | 31 |

The operation

\[ FRT ← [(FRA)´(FRC)] - (FRB) \]

is performed.

The floating-point operand in register FRA is multiplied by the floating-point operand in register FRC. The floating-point operand in register FRB is subtracted from this intermediate result.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of RN and placed into register FRT.

FPRF is set to the class and sign of the result, except for Invalid Operation Exceptions when VE=1.

Special Registers Altered:

| FPRF | FR | FI |
| FX | OX | UX | XX |
| VXSNaN | VXISI | VXIMZ |
CR1 (if Rc=1)

Floating Multiply-Subtract Single A-form

| fmsubs | FRT,FRA,FRC,FRB  | (Rc=0) |
| fmsubs. | FRT,FRA,FRC,FRB  | (Rc=1) |
| 59 | FRT | FRA | FRB | FRC | 28 | % |
| 0 | 6 | 11 | 16 | 21 | 35 | 31 |

The operation

\[ FRT ← [(FRA)´(FRC)] - (FRB) \]

is performed.

The floating-point operand in register FRA is multiplied by the floating-point operand in register FRC. The floating-point operand in register FRB is subtracted from this intermediate result.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of RN and placed into register FRT.

FPRF is set to the class and sign of the result, except for Invalid Operation Exceptions when VE=1.

Special Registers Altered:

| FPRF | FR | FI |
| FX | OX | UX | XX |
| VXSNaN | VXISI | VXIMZ |
CR1 (if Rc=1)
Floating Negative Multiply-Add A-form

\[
\text{fnmadd} \quad \text{FRT,FRA,FRC,FRB} \quad (Rc=0) \\
\text{fnmadd.} \quad \text{FRT,FRA,FRC,FRB} \quad (Rc=1)
\]

The operation
\[
\text{FRT} \leftarrow - ((\text{FRA} \cdot \text{FRC}) + \text{FRB})
\]
is performed.

The floating-point operand in register FRA is multiplied by the floating-point operand in register FRC. The floating-point operand in register FRB is added to this intermediate result.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of RN, then negated and placed into register FRT.

This instruction produces the same result as would be obtained by using the Floating Multiply-Add instruction and then negating the result, with the following exceptions.

- QNaNs propagate with no effect on their “sign” bit.
- QNaNs that are generated as the result of a disabled Invalid Operation Exception have a “sign” bit of 0.
- SNaNs that are converted to QNaNs as the result of a disabled Invalid Operation Exception retain the “sign” bit of the SNaN.

FPRF is set to the class and sign of the result, except for Invalid Operation Exceptions when VE=1.

Special Registers Altered:

\[
\begin{array}{ccccccc}
\text{FPRF} & \text{FR} & \text{FI} \\
\text{FX} & \text{OX} & \text{UX} & \text{XX} \\
\text{VXSNAN} & \text{VXI} & \text{SI} & \text{VXI} & \text{MZ} \\
\text{CR1} & & & & & \\
\end{array}
\]

\[(\text{if Rc=1})\]

Floating Negative Multiply-Add Single A-form

\[
\text{fnmadds} \quad \text{FRT,FRA,FRC,FRB} \quad (Rc=0) \\
\text{fnmadds.} \quad \text{FRT,FRA,FRC,FRB} \quad (Rc=1)
\]

Floating Negative Multiply-Subtract A-form

\[
\text{fnmsub} \quad \text{FRT,FRA,FRC,FRB} \quad (Rc=0) \\
\text{fnmsub.} \quad \text{FRT,FRA,FRC,FRB} \quad (Rc=1)
\]

Floating Negative Multiply-Subtract Single A-form

\[
\text{fnmsubs} \quad \text{FRT,FRA,FRC,FRB} \quad (Rc=0) \\
\text{fnmsubs.} \quad \text{FRT,FRA,FRC,FRB} \quad (Rc=1)
\]

The operation
\[
\text{FRT} \leftarrow - ((\text{FRA} \cdot \text{FRC}) - \text{FRB})
\]
is performed.

The floating-point operand in register FRA is multiplied by the floating-point operand in register FRC. The floating-point operand in register FRB is subtracted from this intermediate result.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of RN, then negated and placed into register FRT.

This instruction produces the same result as would be obtained by using the Floating Multiply-Subtract instruction and then negating the result, with the following exceptions.

- QNaNs propagate with no effect on their “sign” bit.
- QNaNs that are generated as the result of a disabled Invalid Operation Exception have a “sign” bit of 0.
- SNaNs that are converted to QNaNs as the result of a disabled Invalid Operation Exception retain the “sign” bit of the SNaN.

FPRF is set to the class and sign of the result, except for Invalid Operation Exceptions when VE=1.

Special Registers Altered:

\[
\begin{array}{ccccccc}
\text{FPRF} & \text{FR} & \text{FI} \\
\text{FX} & \text{OX} & \text{UX} & \text{XX} \\
\text{VXSNAN} & \text{VXI} & \text{SI} & \text{VXI} & \text{MZ} \\
\text{CR1} & & & & & \\
\end{array}
\]

\[(\text{if Rc=1})\]
4.6.7 Floating-Point Rounding and Conversion Instructions

4.6.7.1 Floating-Point Rounding Instruction

Floating Round to Single-Precision X-form

\[
\begin{array}{c|cccccc}
\text{frsp} & \text{FRB} & \text{Rc} = 0 & \text{FRT} & \text{Rc} = 1 & \text{FRB} & \text{FRT} \\
\hline
0 & 63 & 6 & 11 & 16 & 21 & 31 \\
\end{array}
\]

The floating-point operand in register \( \text{FRB} \) is rounded to single-precision, using the rounding mode specified by \( \text{RN} \), and placed into register \( \text{FRT} \).

The rounding is described fully in Section A.1, “Floating-Point Round to Single-Precision Model” on page 995.

\( \text{FPRF} \) is set to the class and sign of the result, except for Invalid Operation Exceptions when \( \text{VE}=1 \).

Special Registers Altered:

Otherwise, if the rounded value is less than \( -2^{31} \), then the result is \( 0x8000_0000 \), and \( \text{VXCVI} \) is set to 1.

Otherwise, the result is the rounded value converted to 32-bit signed-integer format, and \( \text{XX} \) is set to 1 if the result is inexact.

If an enabled Invalid Operation Exception does not occur, then the result is placed into \( \text{FRT}_{32:63} \) and \( \text{FRT}_{0:31} \) is undefined.

The conversion is described fully in Section A.2, “Floating-Point Convert to Integer Model” on page 999.

Except for enabled Invalid Operation Exceptions, \( \text{FPRF} \) is undefined. \( \text{FR} \) is set if the result is incremented when rounded. \( \text{FI} \) is set if the result is inexact.

Special Registers Altered:

\[ \begin{align*}
&\text{FPRF} \quad \text{(undefined)} \\
&\text{FR} \\
&\text{FI} \\
&\text{FX} \\
&\text{XX} \\
&\text{VXSNAN} \\
&\text{VXCVI} \\
&\text{CR1} \\
\end{align*} \]

\( \text{(if } \text{Rc}=1 \text{) } \)

Floating Convert with round Double-Precision
To Unsigned Word format X-form

Let \( \text{src} \) be the double-precision floating-point value in \( \text{FRB} \).

If \( \text{src} \) is a NaN, then the result is \( 0x0000_0000 \), \( \text{VXCVI} \) is set to 1, and, if \( \text{src} \) is an SNaN, \( \text{VXSNAN} \) is set to 1.

Otherwise, \( \text{src} \) is rounded to a floating-point integer using the rounding mode specified by \( \text{RN} \).

If the rounded value is greater than \( 2^{32} - 1 \), then the result is \( 0xFFF_FFFF \) and \( \text{VXCVI} \) is set to 1.

Otherwise, if the rounded value is less than 0, then the result is \( 0x0000_0000 \) and \( \text{VXCVI} \) is set to 1.

Otherwise, the result is the rounded value converted to 32-bit unsigned-integer format, and \( \text{XX} \) is set to 1 if the result is inexact.

If an enabled Invalid Operation Exception does not occur, then the result is placed into \( \text{FRT}_{32:63} \) and \( \text{FRT}_{0:31} \) is undefined.

The conversion is described fully in Section A.2, “Floating-Point Convert to Integer Model” on page 999.

Except for enabled Invalid Operation Exceptions, \( \text{FPRF} \) is undefined. \( \text{FR} \) is set if the result is incremented when rounded. \( \text{FI} \) is set if the result is inexact.

Special Registers Altered:

\[ \begin{align*}
&\text{FPRF} \quad \text{(undefined)} \\
&\text{FR} \\
&\text{FI} \\
&\text{FX} \\
&\text{XX} \\
&\text{VXSNAN} \\
&\text{VXCVI} \\
&\text{CR1} \\
\end{align*} \]

**Floating Convert with round Unsigned Doubleword to Single-Precision format X-form**

```
fcfidus. FRT,FRB (Rc = 1)
```

The 64-bit unsigned fixed-point operand in register FRB is converted to an infinitely precise floating-point integer. The result of the conversion is rounded to single-precision, using the rounding mode specified by RN, and placed into register FRT.

The conversion is described fully in Section A.3, "Floating-Point Convert from Integer Model".

FPRF is set to the class and sign of the result. FR is set if the result is incremented when rounded. FI is set if the result is inexact.

**Special Registers Altered:**

- FPRF
- FR
- FI
- FX
- XX
- CR1 (if Rc = 1)

**Programming Note**

Converting an unsigned integer word to single-precision floating-point can be accomplished by loading the word from storage using `Load Float Word and Zero Indexed` and then using `fcfidus`.
4.6.7.3 Floating Round to Integer Instructions

The Floating Round to Integer instructions provide direct support for rounding functions found in high level languages. For example, `frin`, `friz`, `frip`, and `frim` implement C++ `round()`, `trunc()`, `ceil()`, and `floor()`, respectively. Note that `frin` does not implement the IEEE Round to Nearest function, which is often further described as “ties to even.” The rounding performed by these instructions is described fully in Section A.4, “Floating-Point Round to Integer Model” on page 1004.

Programming Note

These instructions set FR and FI to 0b00 regardless of whether the result is inexact or rounded because there is a desire to preserve the value of XX. Furthermore, it is believed that most programs do not need to know whether these rounding operations produce inexact or rounded results. If it is necessary to determine whether the result is inexact or rounded, software must compare the result with the original source operand.
### Floating Round to Integer Nearest X-form

<table>
<thead>
<tr>
<th></th>
<th>FRT,FRB</th>
<th>(Rc = 0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>63</td>
<td>11</td>
</tr>
</tbody>
</table>

The floating-point operand in register FRB is rounded to an integral value as follows, with the result placed into register FRT. If the sign of the operand is positive, \((FRB) + 0.5\) is truncated to an integral value, otherwise \((FRB) - 0.5\) is truncated to an integral value.

FPRF is set to the class and sign of the result, except for Invalid Operation Exceptions when VE = 1.

**Special Registers Altered:**
- FPRF: FR (set to 0) FI (set to 0)
- FX
- VXSNAN
- CR1 (if Rc = 1)

### Floating Round to Integer Toward Zero X-form

<table>
<thead>
<tr>
<th></th>
<th>FRT,FRB</th>
<th>(Rc = 0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>63</td>
<td>11</td>
</tr>
</tbody>
</table>

The floating-point operand in register FRB is rounded to an integral value using the rounding mode round toward zero, and the result is placed into register FRT. FPRF is set to the class and sign of the result, except for Invalid Operation Exceptions when VE = 1.

**Special Registers Altered:**
- FPRF: FR (set to 0) FI (set to 0)
- FX
- VXSNAN
- CR1 (if Rc = 1)

### Floating Round to Integer Plus X-form

<table>
<thead>
<tr>
<th></th>
<th>FRT,FRB</th>
<th>(Rc = 0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>63</td>
<td>11</td>
</tr>
</tbody>
</table>

The floating-point operand in register FRB is rounded to an integral value using the rounding mode round toward +infinity, and the result is placed into register FRT. FPRF is set to the class and sign of the result, except for Invalid Operation Exceptions when VE = 1.

**Special Registers Altered:**
- FPRF: FR (set to 0) FI (set to 0)
- FX
- VXSNAN
- CR1 (if Rc = 1)

### Floating Round to Integer Minus X-form

<table>
<thead>
<tr>
<th></th>
<th>FRT,FRB</th>
<th>(Rc = 0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>63</td>
<td>11</td>
</tr>
</tbody>
</table>

The floating-point operand in register FRB is rounded to an integral value using the rounding mode round toward -infinity, and the result is placed into register FRT. FPRF is set to the class and sign of the result, except for Invalid Operation Exceptions when VE = 1.

**Special Registers Altered:**
- FPRF: FR (set to 0) FI (set to 0)
- FX
- VXSNAN
- CR1 (if Rc = 1)
4.6.8 Floating-Point Compare Instructions

The floating-point Compare instructions compare the contents of two floating-point registers. Comparison ignores the sign of zero (i.e., regards +0 as equal to −0). The comparison can be ordered or unordered.

The comparison sets one bit in the designated CR field to 1 and the other three to 0. The FPCC is set in the same way.

**Floating Compare Unordered X-form**

\[
\text{fcmpu BF,FRA,FRB}
\]

<table>
<thead>
<tr>
<th>Bit Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(FRA) &lt; (FRB)</td>
</tr>
<tr>
<td>1</td>
<td>(FRA) &gt; (FRB)</td>
</tr>
<tr>
<td>2</td>
<td>(FRA) = (FRB)</td>
</tr>
<tr>
<td>3</td>
<td>(FRA) ? (FRB) (unordered)</td>
</tr>
</tbody>
</table>

The floating-point operand in register FRA is compared to the floating-point operand in register FRB. The result of the compare is placed into CR field BF and the FPCC.

If either of the operands is a NaN, either quiet or signaling, then CR field BF and the FPCC are set to reflect unordered. If either of the operands is a Signaling NaN, then VXSNAN is set.

**Special Registers Altered:**
- CR field BF
- FPCC
- FX
- VXSNAN

**Floating Compare Ordered X-form**

\[
\text{fcmpo BF,FRA,FRB}
\]

The CR field and the FPCC are set as follows.

<table>
<thead>
<tr>
<th>Bit Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(FRA) &lt; (FRB)</td>
</tr>
<tr>
<td>1</td>
<td>(FRA) &gt; (FRB)</td>
</tr>
<tr>
<td>2</td>
<td>(FRA) = (FRB)</td>
</tr>
<tr>
<td>3</td>
<td>(FRA) ? (FRB) (unordered)</td>
</tr>
</tbody>
</table>

The floating-point operand in register FRA is compared to the floating-point operand in register FRB. The result of the compare is placed into CR field BF and the FPCC.

If either of the operands is a NaN, either quiet or signaling, then CR field BF and the FPCC are set to reflect unordered. If either of the operands is a Signaling NaN, then VXSNAN is set.

If Invalid Operation is disabled (VE=0), VXVC is set. If neither operand is a Signaling NaN but at least one operand is a Quiet NaN, then VXVC is set.

**Special Registers Altered:**
- CR field BF
- FPCC
- FX
- VXSNAN VXVC
4.6.9 Floating-Point Select Instruction

**Floating Select A-form**

.fsella FRT,FRA,FRC,FRB (Rc=0)
.fsela FRT,FRA,FRC,FRB (Rc=1)

<table>
<thead>
<tr>
<th>63</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>26</th>
<th>31</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>FRT</td>
<td>FRA</td>
<td>FRB</td>
<td>FRC</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

if (FRA) \( \geq 0.0 \) then FRT \( \leftarrow \) (FRC)
else FRT \( \leftarrow \) (FRB)

The floating-point operand in register FRA is compared to the value zero. If the operand is greater than or equal to zero, register FRT is set to the contents of register FRC. If the operand is less than zero or is a NaN, register FRT is set to the contents of register FRB. The comparison ignores the sign of zero (i.e., regards +0 as equal to −0).

**Special Registers Altered:**

CR1 (if Rc = 1)

---

**Programming Note**

**Warning:** Care must be taken in using fsel if IEEE compatibility is required, or if the values being tested can be NaNs or infinities.
**fsel Usage Notes**

This section gives examples of how the *Floating Select* instruction can be used to implement certain simple forms of if-then-else constructions, without branching.

The examples show program fragments in an imaginary, C-like, high-level programming language, and the corresponding program fragment using *fsel* and other Power ISA instructions. In the examples, \(a, b, x, y,\) and \(z\) are floating-point variables, which are assumed to be in FPRs \(fa, fb, fx, fy,\) and \(fz\). FPR \(fs\) is assumed to be available for scratch space.

**Warning:** Care must be taken in using *fsel* if IEEE compatibility is required, or if the values being tested can be NaNs or infinities; see Section ...

### Comparison to Zero

<table>
<thead>
<tr>
<th>High-level language:</th>
<th>Power ISA:</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>if (a \geq 0.0) then (x \leftarrow y) else (x \leftarrow z)</td>
<td><em>fsel</em> (fx, fa, fy, fz)</td>
<td>(1)</td>
</tr>
<tr>
<td>if (a &gt; 0.0) then (x \leftarrow y) else (x \leftarrow z)</td>
<td>(fneg) (fs, fa) <em>fsel</em> (fx, fs, fz, fy)</td>
<td>(1, 2)</td>
</tr>
<tr>
<td>if (a = 0.0) then (x \leftarrow y) else (x \leftarrow z)</td>
<td><em>fsel</em> (fx, fa, fy, fz) (fneg) (fs, fa) <em>fsel</em> (fx, fs, fz, fz)</td>
<td>(1)</td>
</tr>
</tbody>
</table>

### Simple if-then-else Constructions

<table>
<thead>
<tr>
<th>High-level language:</th>
<th>Power ISA:</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>if (a \geq b) then (x \leftarrow y) else (x \leftarrow z)</td>
<td><em>fsub</em> (fs, fa, fb) <em>fsel</em> (fx, fs, fy, fz)</td>
<td>(4, 5)</td>
</tr>
<tr>
<td>if (a &gt; b) then (x \leftarrow y) else (x \leftarrow z)</td>
<td>(fneg) (fs, fs) (fneg) (fs, fs) <em>fsel</em> (fx, fs, fx, fz)</td>
<td>(3, 4, 5)</td>
</tr>
<tr>
<td>if (a = b) then (x \leftarrow y) else (x \leftarrow z)</td>
<td>(fneg) (fs, fs) (fneg) (fs, fs) <em>fsel</em> (fx, fs, fx, fz)</td>
<td>(4, 5)</td>
</tr>
</tbody>
</table>

**Notes:**

The following Notes apply to the preceding examples and to the corresponding cases using the other three arithmetic relations \(<, \leq,\) and \(!=\). They should also be considered when any other use of *fsel* is contemplated.

In these Notes, the “optimized program” is the Power ISA program shown, and the "unoptimized program" (not shown) is the corresponding Power ISA program that uses *fcmpeq* and *Branch Conditional* instructions instead of *fsel*.

1. The unoptimized program affects the \(VXSNAN\) bit of the FPSCR, and therefore may cause the system error handler to be invoked if the corresponding exception is enabled, while the optimized program does not affect this bit. This property of the optimized program is incompatible with the IEEE standard.

2. The optimized program gives the incorrect result if \(a\) is a NaN.

3. The optimized program gives the incorrect result if \(a\) and/or \(b\) is a NaN (except that it may give the correct result in some cases for the minimum and maximum functions, depending on how those functions are defined to operate on NaNs).

4. The optimized program gives the incorrect result if \(a\) and \(b\) are infinities of the same sign. (Here it is assumed that Invalid Operation Exceptions are disabled, in which case the result of the subtraction is a NaN. The analysis is more complicated if Invalid Operation Exceptions are enabled, because in that case the target register of the subtraction is unchanged.)

5. The optimized program affects the \(OX, UX, XX,\) and \(VXSI\) bits of the FPSCR, and therefore may cause the system error handler to be invoked if the corresponding exceptions are enabled, while the unoptimized program does not affect these bits. This property of the optimized program is incompatible with the IEEE standard.
4.6.10 Floating-Point Status and Control Register Instructions

Except as described below for \( \text{mffsce, mffscdrn}[i] \), \( \text{mffscrn}[i] \), and \( \text{mffsl} \), Floating-Point Status and Control Register instructions synchronize the effects of all floating-point instructions executed by a given processor. Executing a Floating-Point Status and Control Register instruction ensures that all floating-point instructions previously initiated by the given processor have completed before the Floating-Point Status and Control Register instruction is initiated, and that no subsequent floating-point instructions are initiated by the given processor until the Floating-Point Status and Control Register instruction has completed. In particular:

- All exceptions that will be caused by the previously initiated instructions are recorded in the FPSCR before the Floating-Point Status and Control Register instruction is initiated.
- All invocations of the system floating-point enabled exception error handler that will be caused by the previously initiated instructions have occurred before the Floating-Point Status and Control Register instruction is initiated.
- No subsequent floating-point instruction that depends on or alters the settings of any FPSCR bits is initiated until the Floating-Point Status and Control Register instruction has completed.

While not satisfying all of the conditions described above, \( \text{mffsce, mffscdrn}[i] \), \( \text{mffscrn}[i] \), and \( \text{mffsl} \) still obey the sequential execution model. Any FPSCR status bits read by \( \text{mffsce} \) or \( \text{mffsl} \) will reflect updates due to all preceding floating-point instructions. That is, all floating-point instructions following an \( \text{mffsce, mffscdrn}[i] \), or \( \text{mffscrn}[i] \) will execute based on any updates applied to any control bits in the FPSCR by the \( \text{mffsce, mffscdrn}[i] \), or \( \text{mffscrn}[i] \).

(Floating-point Storage Access instructions are not affected.)

The instruction descriptions in this section refer to “FPSCR fields,” where FPSCR field \( k \) is FPSCR bits \( 4k:4k+3 \).

### Move From FPSCR X-form

**mffs FRT**

\( \text{(Rc=0)} \)

**mffs. FRT**

\( \text{(Rc=1)} \)

<table>

<th>11</th>
<th>16</th>
<th>//</th>
<th>583</th>
<th>Rc</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>//</td>
<td>21</td>
<td>583</td>
</tr>
</tbody>
</table>

The contents of the FPSCR are placed into register FRT.

If \( \text{Rc=1} \), CR field 1 is set to the value \( FX||FE||WX||OX \).

**Special Registers Altered:**

\( \text{CR1} \)

\( \text{(if Rc=1)} \)

### Move From FPSCR & Clear Enables X-form

**mffsce FRT**

The contents of bits 56:60 (\( \text{VE, OE, UE, ZE, XE} \)) of the FPSCR are set to 0.

**Special Registers Altered:**

\( \text{VE (set to 0) OE (set to 0) UE (set to 0) ZE (set to 0) XE (set to 0)} \)

### Move From FPSCR Control & Set DRN X-form

**mffscdrn FRT,FRB**

Let \( \text{new}_{-}\text{DRN} \) be the contents of bits 29:31 of register FRB.

The contents of the control bits in the FPSCR, that is, bits 29:31 (\( \text{DRN} \)) and bits 56:63 (\( \text{VE, OE, UE, ZE, XE, NI, RN} \)), are placed into the corresponding bits in register FRT. All other bits in register FRT are set to 0.

\( \text{new}_{-}\text{DRN} \) is placed into bits 62:64 of the FPSCR (\( \text{DRN} \)).

**Special Registers Altered:**

\( \text{DRN} \)

**Programming Note**

\( \text{mffscdrn} \) permits software to simultaneously read control bits in the FPSCR and set the DRN field without the higher latency typically associated with accessing the status bits.
Move From FPSCR Control & Set DRN Immediate X-form

\[
mffscdri \quad \text{FRT,DRM}
\]

<table>
<thead>
<tr>

<th>BF // BFA // // /// 64 //</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6  9 11 14 16 21 31</td>
</tr>
</tbody>
</table>

The contents of FPSCR32:63 field BFA are copied to Condition Register field BF. All exception bits copied are set to 0 in the FPSCR. If the FX bit is copied, it is set to 0 in the FPSCR.

Special Registers Altered:

CR field

BF FX (if BFA=0)
UX ZX XX VXSAN (if BFA=1)
VXSI VXDI VXZDZ VXMZ (if BFA=2)
VXVC (if BFA=3)
VXSOFT VXSOQT VXCVI (if BFA=5)

Move To FPSCR Field Immediate X-form

mtfsfi BF,U,W

<table>
<thead>
<tr>
<th>63</th>
<th>BF // /// W U // 134 //</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6  9 11 14 16 21 22 31</td>
</tr>
</tbody>
</table>

The value of the U field is placed into FPSCR field BF+8*(1-W).

FX is altered only if BF=0 and W=0.

Special Registers Altered:

FPSCR field BF + 8*(1-W)
CR1 (if Rc=1)

mtfsfi serves as both a basic and an extended mnemonic. The Assembler will recognize a mtfsfi mnemonic with three operands as the basic form, and a mtfsfi mnemonic with two operands as the extended form. In the extended form the W operand is omitted and assumed to be 0.

Programming Note

When FPSCR32:35 is specified, bits 32 (FX) and 35 (OX) are set to the values of U2 and U3 (i.e., even if this instruction causes OX to change from 0 to 1, FX is set from U2 and not by the usual rule that FX is set to 1 when an exception bit changes from 0 to 1). Bits 33 and 34 (FEX and VX) are set according to the usual rule, given on page 133, and not from U3:2.

Move To FPSCR Fields XFL-form

mtfsf FLM,FRB,L,W

<table>
<thead>
<tr>
<th>63</th>
<th>L</th>
<th>FLM // 134 // FRB 711 //</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>7 11 14 16 21 22 31</td>
</tr>
</tbody>
</table>

The FPSCR is modified as specified by the FLM, L, and W fields.

L=0

The contents of register FRB are placed into the FPSCR under control of the W field and the field mask specified by FLM. W and the field mask identify the 4-bit fields affected. Let i be an integer in the range 0-7. If FLM_i=1 then FPSCR field k is set to the contents of the corresponding field of register FRB, where k=i+8*(1-W).

L=1

The contents of register FRB are placed into the FPSCR.

FX is not altered implicitly by this instruction.

Special Registers Altered:

FPSCR fields selected by mask, L, and W CR1 (if Rc=1)

Programming Note

mtfsf serves as both a basic and an extended mnemonic. The Assembler will recognize a mtfsf mnemonic with four operands as the basic form, and a mtfsf mnemonic with two operands as the extended form. In the extended form the W and L operands are omitted and both are assumed to be 0.

Programming Note

If L=1 or if L=0 and FPSCR32:35 is specified, bits 32 (FX) and 35 (OX) are set to the values of (FRB)32 and (FRB)35 (i.e., even if this instruction causes OX to change from 0 to 1, FX is set from (FRB)32 and not by the usual rule that FX is set to 1 when an exception bit changes from 0 to 1). Bits 33 and 34 (FEX and VX) are set according to the usual rule, given on page 133, and not from (FRB)33:34.
Move To FPSCR Bit 0 X-form

\begin{align*}
\text{mtfsb0} & \quad \text{BT} \quad (Rc=0) \\
\text{mtfsb0} \cdot & \quad \text{BT} \quad (Rc=1)
\end{align*}

Bit BT+32 of the FPSCR is set to 0.

Special Registers Altered:
- FPSCR bit BT+32
- CR1 \quad (if Rc=1)

\begin{table}
\begin{tabular}{cccccc}
63 & 6 & 11 & 16 & 21 & 31 \\
0 & & & & &

\end{table}

Programming Note

Bits 33 and 34 (FEX and VX) cannot be explicitly reset.

Move To FPSCR Bit 1 X-form

\begin{align*}
\text{mtfsb1} & \quad \text{BT} \quad (Rc=0) \\
\text{mtfsb1} \cdot & \quad \text{BT} \quad (Rc=1)
\end{align*}

Bit BT+32 of the FPSCR is set to 1.

Special Registers Altered:
- FPSCR bits BT+32 and FX
- CR1 \quad (if Rc=1)

\begin{table}
\begin{tabular}{cccccc}
63 & 6 & 11 & 16 & 21 & 31 \\
0 & & & & &
\end{tabular}
\end{table}

Programming Note

Bits 33 and 34 (FEX and VX) cannot be explicitly set.
Chapter 5. Decimal Floating-Point

5.1 Decimal Floating-Point (DFP) Facility Overview

This chapter describes the behavior of the decimal floating-point facility, the supported data types, formats, and classes, and the usage of registers. Also included are the execution model, exceptions, and instructions supported by the decimal floating-point facility.

The decimal floating-point (DFP) facility shares the 32 floating-point registers (FPRs) and the Floating-Point Status and Control Register (FPSCR) with the floating-point (BFP) facility. However, the interpretation of data formats in the FPRs, and the meaning of some control and status bits in the FPSCR are different between the BFP and DFP facilities.

The DFP facility also shares the Condition Register (CR) with the fixed-Point facility, the BFP facility, and the vector facility.

The DFP facility supports three DFP data formats: DFP Short (single precision), DFP Long (double precision), and DFP Extended (quad precision). Most operations are performed on DFP Long or DFP Extended format directly. Support for DFP Short is limited to conversion to and from DFP Long. Some DFP instructions operate on other data types, including signed or unsigned binary fixed-point data, and signed or unsigned decimal data.

DFP instructions are provided to perform arithmetic, compare, test, quantum-adjustment, conversion, and format operations on operands held in FPRs or FPR pairs.

- Arithmetic instructions
  These instructions perform addition, subtraction, multiplication, and division operations.

- Compare instructions
  These instructions perform a comparison operation on the numerical value of two DFP operands.

- Test instructions
  These instructions test the data class, the data group, the exponent, or the number of significant digits of a DFP operand.

- Quantum-adjustment instructions
  These instructions convert a DFP number to a result in the form that has the designated exponent, which may be explicitly or implicitly specified.

- Conversion instructions
  These instructions perform conversion between different data formats or data types.

- Format instructions
  These instructions facilitate composing or decomposing a DFP operand.

These instructions are described in Section 5.6 “DFP Instruction Descriptions” on page 205.

The three DFP data formats allow finite numbers to be represented with different precision and ranges. Special codes are also provided to represent +Infinity, -Infinity, Quiet NaN (Not-a-Number), and Signaling NaN. Operations involving infinities produce results obeying traditional mathematical conventions. NaNs have no mathematical interpretation. The encoding of NaNs provides a diagnostic information field. This diagnostic field may be used to indicate such things as the source of an uninitialized variable or the reason an invalid result was produced.

The DFP processor recognizes a set of DFP exceptions which are indicated via bits set in the FPSCR. Additionally, the DFP exception actions depend on the setting of the various exception enable bits in the FPSCR.
The following DFP exceptions are detected by the DFP processor. The exception status bits in the FPSCR are indicated in parentheses.

- Invalid Operation Exception (VX)
  - SNaN (VXSNAN)
  - ∞ - ∞ (VXI SI)
  - ∞ ÷ ∞ (VXI DI)
  - 0 ÷ 0 (VXZDZ)
  - ∞ × 0 (VXIMZ)
  - Invalid Compare (VXVC)
  - Invalid conversion (VXCVI)

- Zero Divide Exception (ZX)

- Overflow Exception (OX)

- Underflow Exception (UX)

- Inexact Exception (XX)

Each DFP exception and each category of Invalid Operation Exception has an exception status bit in the FPSCR. In addition, each of the five DFP exceptions has a corresponding enable bit in the FPSCR. These enable bits enable or disable the invocation of the system floating-point enabled exception error handler, and may affect the setting of some exception status bits in the FPSCR.

The usage of these bits by the DFP facility differs from the usage by the BFP facility. Section 5.5.10 “DFP Exceptions” on page 197 provides a detailed discussion of DFP exceptions, including the effects of the enable bits.

### 5.2 DFP Register Handling

The following sections describe first how the floating-point registers are utilized by the DFP facility. The subsequent section covers the DFP usage of CR and FPSCR.

#### 5.2.1 DFP Usage of Floating-Point Registers

The DFP facility shares the same 32 64-bit FPRs with the BFP facility. Like the FP instructions, DFP instructions also use 5-bit fields for designating the FPRs to hold the source or target operands.

When data in DFP Short format is held in a FPR, it occupies the rightmost 32 bits of the FPR. The Load Floating-Point as Integer Word Algebraic instruction is provided to load the rightmost 32 bits of a FPR with a single-word data from storage. The Store Floating-Point as Integer Word instruction is available to store the rightmost 32 bits of a FPR to a storage location.

Data in DFP Long format, 64-bit binary fixed-point values, or 64-bit BCD values is held in a FPR using all 64 bits. Data of 64 bits may be loaded from storage via any of the Load Floating-Point Double instructions and stored via any of the Store Floating-Point Double instructions.

Data in DFP Extended format or 128-bit BCD values is held in an even-odd FPR pair using all 128 bits. Data of 128 bits must be loaded into the desired even-odd pair of floating-point registers using an appropriate sequence of the Load Floating-Point Double instructions and stored using an appropriate sequence of the Store Floating-Point Double instructions.

Data used as a source operand by any Decimal Floating-Point instruction that was produced, either directly or indirectly, by a Load Floating-Point Single instruction, a Floating Round to Single-Precision instruction, or a binary floating-point single-precision arithmetic instruction is boundedly undefined.

When an even-odd FPR pair is used to hold a 128-bit operand, the even-numbered FPR is used to hold the leftmost doubleword of the operand and the next higher-numbered FPR is used to hold the rightmost doubleword. A DFP instruction designating an odd-numbered FPR for a 128-bit operand is an invalid instruction form.

### Bit Definitions

<table>
<thead>
<tr>
<th>Bit(s)</th>

</tr>
<tr>
<td>29:31</td>
<td>DFP Rounding Control (DRN)</td>
</tr>
<tr>
<td>32</td>
<td>Floating-Point Exception Summary (FX)</td>
</tr>
</tbody>
</table>

### Programming Note

The Floating-Point Move instructions can be used to move operands between FPRs.

The bit definitions for the FPSCR are as follows.

#### Programming Note

FPSCR28 is reserved for extension of the DRN field, therefore DRN may be set using the mtfsfi instruction to set the rounding mode.

Floating-Point Exception Summary (FX)

Every floating-point instruction, except mtfsi and mtfs, implicitly sets FX to 1 if that instruction causes any of the floating-point exception bits in the FPSCR to change from 0 to 1.
**Floating-Point Fraction Rounded (FF)**
The last Arithmetic or Rounding and Conversion instruction incremented the fraction during rounding. See Section 5.5.1, “Rounding” on page 194. This bit is not sticky.

**Floating-Point Inexact (FI)**
The last Arithmetic or Rounding and Conversion instruction either produced an inexact result during rounding or caused a disabled Overflow Exception. See Section 5.5.1. This bit is not sticky.

See the definition of XX, above, regarding the relationship between FI and XX.

**Floating-Point Result Flags (FPRF)**
This field is set as described below. For arithmetic, rounding, and conversion instructions, the field is set based on the result placed into the target register, except that if any portion of the result is undefined then the value placed into FPRF is undefined.

**Floating-Point Result Class Descriptor (C)**
Arithmetic, rounding, and conversion instructions may set this bit with the FPRC bits, to indicate the class of the result as shown in Figure 58 on page 190.

**Floating-Point Condition Code (FPCC)**
Floating-point Compare and DFP Test instructions set one of the FPCC bits to 1 and the other three FPCC bits to 0. Arithmetic, rounding, and conversion instructions may set the FPCC bits with the C bit, to indicate the class of the result as shown in Figure 58 on page 190. Note that in this case the high-order three bits of the FPCC retain their relational significance indicating that the value is less than, greater than, or equal to zero.

**Floating-Point Less Than or Negative (FL or <)**

**Floating-Point Greater Than or Positive (FG or >)**

**Floating-Point Equal or Zero (FE or =)**

**Floating-Point Unordered or NaN (FU or ?)**
Reserved

**Floating-Point Invalid Operation Exception (Software Request) (VXSOFT)**
This bit can be altered only by **mcrfs, mtfsfi, mtfsf, mtfsb0, or mtfsb1**. See Section 5.5.10.1, “Invalid Operation Exception” on page 199.

Neither used nor changed by DFP.

---

Floating-Point Enabled Exception Summary (FEX)
This bit is the OR of all the floating-point exception bits masked by their respective enable bits. **mcrfs, mtfsfi, mtfsf, mtfsb0,** and **mtfsb1** cannot alter FEX explicitly.

Floating-Point Invalid Operation Exception Summary (XX)
This bit is the OR of all the Invalid Operation exception bits. **mcrfs, mtfsfi, mtfsf, mtfsb0,** and **mtfsb1** cannot alter XX explicitly.

Floating-Point Overflow Exception (OX)
See Section 5.5.10.3, “Overflow Exception” on page 201.

Floating-Point Underflow Exception (UX)
See Section 5.5.10.4, “Underflow Exception” on page 201.

Floating-Point Zero Divide Exception (ZX)
See Section 5.5.10.2, “Zero Divide Exception” on page 200.

Floating-Point Inexact Exception (XX)
See Section 5.5.10.5, “Inexact Exception” on page 202.

XX is a sticky version of FI (see below). Thus the following rules completely describe how XX is set by a given instruction:

- If the instruction affects FI, the new value of XX is obtained by ORing the old value of XX with the new value of FI.
- If the instruction does not affect FI, the value of XX is unchanged.

Floating-Point Invalid Operation Exception (VXSNAN)
See Section 5.5.10.1, “Invalid Operation Exception” on page 199.

Floating-Point Invalid Operation Exception (Infinity – Infinity) (VXI SI)
See Section 5.5.10.1.

Floating-Point Invalid Operation Exception (Infinity > Infinity) (VXI DI)
See Section 5.5.10.1.

Floating-Point Invalid Operation Exception (Zero > Zero) (VX2ZD)
See Section 5.5.10.1.

Floating-Point Invalid Operation Exception (Infinity × Zero) (VX1 MZ)
See Section 5.5.10.1.

Floating-Point Invalid Operation Exception (Invalid Compare) (VXVC)
See Section 5.5.10.1.

Floating-Point Enabled Exception Summary (FEX)
This bit is the OR of all the floating-point exception bits masked by their respective enable bits. **mcrfs, mtfsfi, mtfsf, mtfsb0,** and **mtfsb1** cannot alter FEX explicitly.

Floating-Point Overflow Exception
This bit is the OR of all the Invalid Operation exception bits. **mcrfs, mtfsfi, mtfsf, mtfsb0,** and **mtfsb1** cannot alter XX explicitly.

Floating-Point Inexact Exception (XX)
See Section 5.5.10.5, “Inexact Exception” on page 202.

XX is a sticky version of FI (see below). Thus the following rules completely describe how XX is set by a given instruction:

- If the instruction affects FI, the new value of XX is obtained by ORing the old value of XX with the new value of FI.
- If the instruction does not affect FI, the value of XX is unchanged.

Floating-Point Invalid Operation Exception (VXSNAN)
See Section 5.5.10.1, “Invalid Operation Exception” on page 199.
5.3 DFP Support for Non-DFP Data Types

In addition to the DFP data types, the DFP processor provides limited support for the following non-DFP data types: signed or unsigned binary fixed-point data, and signed or unsigned decimal data.

In unsigned binary fixed-point data, all bits are used to express the absolute value of the number. For signed binary fixed-point data, the leftmost bit represents the sign, which is followed by the numeric field. Positive numbers are represented in true binary notation with the sign bit set to zero. When the value is zero, all bits are zeros, including the sign bit. Negative numbers are represented in two's complement binary notation with a one in the sign-bit position.

For decimal data, each byte contains a pair of four-bit nibbles; each four-bit nibble contains a binary-coded-decimal (BCD) code. There are two kinds of BCD codes: digit code and sign code. For unsigned decimal data, all nibbles contain a digit code as shown in Figure 59.

![Figure 59. Format for Unsigned Decimal Data](image_url)

For signed decimal data, the rightmost nibble contains a sign code (S) and all other nibbles contain a digit code as shown in Figure 60.

![Figure 60. Format for Signed Decimal Data](image_url)

The decimal digits 0-9 have the binary encoding 0000-1001. The preferred plus-sign codes are 1100 and 1111. The preferred minus sign code is 1101. These are the sign codes generated for the results of the Decode DPD To BCD instruction. A selection is provided by this instruction to specify which of the two preferred plus sign codes is to be generated. Alternate sign codes are also recognized as valid in the sign position: 1010 and 1011 are alternate sign codes for plus, and 1011 is an alternate sign code for minus. Alternate sign codes are accepted for any source operand, but are not generated as a result by the instruction. When an invalid digit or sign code is detected by the Encode BCD To DPD instruction, an invalid-operation exception occurs. A
5.4 DFP Number Representation

A DFP finite number consists of three components: a sign bit, a signed exponent, and a significand. The signed exponent is a signed binary integer. The significand consists of a number of decimal digits, which are to the left of the implied decimal point. The rightmost digit of the significand is called the units digit. The numerical value of a DFP finite number is represented as \((-1)^{\text{sign}} \times \text{significand} \times 10^{\text{exponent}}\) and the unit value of this number is \((1 \times 10^{\text{exponent}})\), which is called the quantum.

DFP finite numbers are not normalized. This allows leading zeros and trailing zeros to exist in the significand. This unnormalized DFP number representation allows some values to have redundant forms; each form represents the DFP number with a different combination of the significand value and the exponent value. For example, \(1000000 \times 10^5\) and \(10 \times 10^{10}\) are two different forms of the same numerical value. A form of this number representation carries information about both the numerical value and the quantum of a DFP finite number.

The significant digits of a DFP finite number are the digits in the significand beginning with the leftmost non-zero digit and ending with the units digit.

### 5.4.1 DFP Data Format

DFP numbers and NaNs may be represented in FPRs in any of the three data formats: DFP Short, DFP Long, or DFP Extended. The contents of each data format represent encoded information. Special codes are assigned to NaNs and infinities. Different formats support different sizes in both significand and exponent. Arithmetic, compare, test, quantum-adjustment, and format instructions are provided for DFP Long and DFP Extended formats only.

The sign is encoded as a one bit binary value. Significand is encoded as an unsigned decimal integer in two distinct parts. The leftmost digit (LMD) of the significand is encoded as part of the combination field; the remaining digits of the significand are encoded in the trailing significand field. The exponent is contained in the combination field in two parts. However, prior to encoding, the exponent is converted to an unsigned binary value called the biased exponent by adding a bias value which is a constant for each format. The two leftmost bits of the biased exponent are encoded with the leftmost digit of the significand in the leftmost bits of the combination field. The rest of the biased exponent occupies the remaining portion of the combination field.

### 5.4.1.1 Fields Within the Data Format

The DFP data representation comprises three fields, as diagrammed below for each of the three formats:

#### DFP Short format

- **Sign bit (S)**
- **Combination field (G)**
- **Trailing significand (T)**

#### DFP Long format

- **Sign bit (S)**
- **Combination field (G)**
- **Trailing significand (T)**

#### DFP Extended format

- **Sign bit (S)**
- **Combination field (G)**
- **Trailing significand (T)**

The fields are defined as follows:

- **Sign bit (S)**
  
The sign bit is in bit 0 of each format, and is zero for plus and one for minus.

- **Combination field (G)**
  
  As the name implies, this field provides a combination of the exponent and the left-most digit (LMD) of the significand, for finite numbers, or provides a special code.
for denoting the value as either a Not-a-Number or an Infinity.

The first 5 bits of the combination field contain the encoding of NaN or infinity, or the two leftmost bits of the biased exponent and the leftmost digit (LMD) of the significand. The following tables show the encoding:

<table>
<thead>
<tr>
<th>G₀:₄</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>11111</td>
<td>NaN</td>
</tr>
<tr>
<td>11110</td>
<td>Infinity</td>
</tr>
<tr>
<td>All others</td>
<td>Finite Number (see Figure 66)</td>
</tr>
</tbody>
</table>

<td>11001</td>
</tr>
</tbody>
</table>

Figure 66. Encoding of bits 0:4 of the G field for Finite Numbers

For DFP finite numbers, the rightmost N-5 bits of the N-bit combination field contain the remaining bits of the biased exponent. For NaNs, bit 5 of the combination field is used to distinguish a Quiet NaN from a Signaling NaN; the remaining bits in a source operand are ignored and they are set to zeros in a target operand by most operations. For infinities, the rightmost N-5 bits of the N-bit combination field of a source operand are ignored and they are set to zeros in a target operand by most operations.

**Trailing Significand field (T)**

For DFP finite numbers, this field contains the remaining *(significant digits). For NaNs, this field may be used to contain diagnostic information. For infinities, contents in this field of a source operand are ignored and they are set to zeros in a target operand by most operations. The trailing significand field is a multiple of 10-bit blocks. The multiple depends on the format. Each 10-bit block is called a declet and represents three decimal digits, using the Densely Packed Decimal (DPD) encoding defined in Appendix B.

### 5.4.1.2 Summary of DFP Data Formats

The properties of the three DFP formats are summarized in the following table:

<table>
<thead>
<tr>

</tbody>
</table>

Figure 67. Summary of DFP Formats
5.4.1.3 Preferred DPD Encoding

Execution of DFP instructions decodes source operands from DFP data formats to an internal format for processing, and encodes the operation result before the final result is returned as the target operand.

As part of the decoding process, declets in the trailing significand field of source operands are decoded to their corresponding BCD digit codes using the DPD-to-BCD decoding algorithm. As part of the encoding process, BCD digit codes to be stored into the trailing significand field of the target operand are encoded into declets using the BCD-to-DPD encoding algorithm. Both the decoding and encoding algorithms are defined in Appendix B.

As explained in Appendix B, there are eight 3-digit decimal values that have redundant DPD codes and one preferred DPD code. All redundant DPD codes are recognized in source operands for the associated 3-digit decimal number. DFP operations will always generate the preferred DPD codes for the trailing significand field of the target operand.

5.4.2 Classes of DFP Data

There are six classes of DFP data, which include numerical and nonnumeric entities. The numerical entities include zero, subnormal number, normal number, and infinity data classes. The nonnumeric entities include quiet and signaling NaNs data classes. The value of a DFP finite number, including zero, subnormal number, and normal number, is a quantization of the real number based on the data format. The Test Data Class instruction may be used to determine the class of a DFP operand. In general, an operation that returns a DFP result sets the FPRF field to indicate the data class of the result.

The following tables show the value ranges for finite-number data classes, and the codes for NaNs and infinities.

<table>
<thead>
<tr>
<th>Data Class</th>
<th>Sign</th>
<th>Magnitude</th>

![Figure 69. Encoding of NaN and Infinity Data Classes](image)

**Zeros**

Zeros have a zero significand and any representable value in the exponent. A +0 is distinct from -0, and zeros with different exponents are distinct, except that comparison treats them as equal.

**Subnormal Numbers**

Subnormal numbers have values that are smaller than $N_{\text{min}}$, and greater than zero in magnitude.

**Normal Numbers**

Normal numbers are nonzero finite numbers whose magnitude is between $N_{\text{min}}$ and $N_{\text{max}}$ inclusively.

**Infinities**

Infinities are represented by $0b11110$ in the leftmost 5 bits of the combination field. When an operation is defined to generate an infinity as the result, a default infinity is sometimes supplied. A default infinity has all remaining bits in the combination field and trailing significand field set to zeros.

When infinities are used as source operands, only the leftmost 5 bits of the combination field are interpreted (i.e., $0b11110$ indicates the value is an infinity). The trailing significand field of infinities is usually ignored. For generated infinities, the leftmost 5 bits of the combination field are set to $0b11110$ and all remaining combination bits are set to zero.

Infinities can participate in most arithmetic operations and give a consistent result. In comparisons, any +Infinity compares greater than any finite number, and any -Infinity compares less than any finite number. All +Infinity are compared equal and all -Infinity are compared equal.

**Signaling and Quiet NaNs**

There are two types of Not-a-Numbers (NaNs), Signaling (SNaN) and Quiet (QNaN).

$0b111110$ in the leftmost 6 bits of the combination field indicates a Quiet NaN, whereas $0b111111$ indicates a Signaling NaN.

A special QNaN is sometimes supplied as the default QNaN for a disabled invalid-operation exception; it has a plus sign, the leftmost 6 bits of the combination field set to $0b111110$ and remaining bits in the combination field and the trailing significand field set to zero.

Normally, source QNaNs are propagated during operations so that they will remain visible at the end. When a
QNaN is propagated, the sign is preserved, the decimal value of the trailing significand field is preserved but reencoded using the preferred DPD codes, and the contents in the rightmost \( n - 6 \) bits of the combination field set to zero, where \( n \) is the width of the combination field for the format.

A source SNaN generally causes an invalid-operation exception. If the exception is disabled, the SNaN is converted to the corresponding QNaN and propagated. The primary encoding difference between an SNaN and a QNaN is that bit 5 of an SNaN is 1 and bit 5 of a QNaN is 0. When an SNaN is propagated as a QNaN, bit 5 is set to 0, and, just as with QNaN propagation, the sign is preserved, the decimal value of the trailing significand field is preserved but reencoded using the preferred DPD codes, and the contents in the rightmost \( n - 6 \) bits of the combination field set to zero, where \( n \) is the width of the combination field for the format. For some format-conversion instructions, a source SNaN does not cause an invalid-operation exception, and an SNaN is returned as the target operand.

For instructions with two source NaNs and a NaN is to be propagated as the result, do the following.
- If there is a QNaN in \( F_R \) and an SNaN in \( F_B \), the SNaN in \( F_R \) is propagated.
- Otherwise, propagate the NaN is \( F_R \).

5.5 DFP Execution Model

DFP operations are performed as if they first produce an intermediate result correct to infinite precision and with unbounded range. The intermediate result is then rounded to the destination’s precision according to one of the eight DFP rounding modes. If the rounded result has only one form, it is delivered as the final result; if the rounded result has redundant forms, then an ideal exponent is used to select the form of the final result. The ideal exponent determines the form, not the value, of the final result. (See Section 5.5.3 “Formation of Final Result” on page 195.)

5.5.1 Rounding

Rounding takes a number regarded as infinitely precise and, if necessary, modifies it to fit the destination’s precision. The destination’s precision of an operation defines the set of permissible resultant values. For most operations, the destination’s precision is the target-format precision and the permissible resultant values are those values representable in the target format. For some special operations, the destination precision is constrained by both the target format and some additional restrictions, and the permissible resultant values are a subset of the values representable in the target format.

Rounding sets FPSCR bits \( F_R \) and \( F_I \). When an inexact exception occurs, \( F_I \) is set to one; otherwise, \( F_I \) is set to zero. When an inexact exception occurs and if the rounded result is greater in magnitude than the intermediate result, then \( F_R \) is set to one; otherwise, \( F_R \) is set to zero. The exception is the Round to FP Integer Without Inexact instruction, which always sets \( F_R \) and \( F_I \) to zero. Rounding may cause an overflow exception or underflow exception; it may also cause an inexact exception.

Refer to Figure 70 below for rounding. Let \( Z \) be the intermediate result of a DFP operation. \( Z \) may or may not fit in the destination’s precision. If \( Z \) is exactly one of the permissible representable resultant values, then the final result in all rounding modes is \( Z \). Otherwise, either \( Z_1 \) or \( Z_2 \) is chosen to approximate the result, where \( Z_1 \) and \( Z_2 \) are the next larger and smaller permissible resultant values, respectively.

![Figure 70. Rounding](image)

**Round to Nearest, Ties to Even**

Choose the value that is closer to \( Z \) (\( Z_1 \) or \( Z_2 \)). In case of a tie, choose the one whose units digit would have been even in the form with the largest common quantum of the two permissible resultant values. However, an infinitely precise result with magnitude at least \( (N_{max} + 0.5Q(N_{max})) \) is rounded to infinity with no change in sign; where \( Q(N_{max}) \) is the quantum of \( N_{max} \).

**Round toward 0**

Choose the smaller in magnitude (\( Z_1 \) or \( Z_2 \)).

**Round toward \( +\infty \)**

Choose \( Z_1 \).

**Round toward \( -\infty \)**

Choose \( Z_2 \).

**Round to Nearest, Ties away from 0**

Choose the value that is closer to \( Z \) (\( Z_1 \) or \( Z_2 \)). In case of a tie, choose the larger in magnitude (\( Z_1 \) or \( Z_2 \)). However, an infinitely precise result with magnitude at least \( (N_{max} + 0.5Q(N_{max})) \) is rounded to infinity with no change in sign; where \( Q(N_{max}) \) is the quantum of \( N_{max} \).

**Round to Nearest, Ties toward 0**

Choose the value that is closer to \( Z \) (\( Z_1 \) or \( Z_2 \)). In case of a tie, choose the smaller in magnitude (\( Z_1 \) or \( Z_2 \)). However, an infinitely precise result with magnitude greater than \( (N_{max} + 0.5Q(N_{max})) \) is rounded to infinity.
with no change in sign; where $Q(N_{max})$ is the quantum of $N_{max}$.

**Round away from 0**
Choose the larger in magnitude ($Z_1$ or $Z_2$).

**Round to prepare for shorter precision**
Choose the smaller in magnitude ($Z_1$ or $Z_2$). If the selected value is inexact and the units digit of the selected value is either 0 or 5, then the digit is incremented by one and the incremented result is delivered. In all other cases, the selected value is delivered. When a value has redundant forms, the units digit is determined by using the form that has the smallest exponent.

### 5.5.2 Rounding Mode Specification

Unless otherwise specified in the instruction definition, the rounding mode used by an operation is specified in the DFP rounding control (DRN) field of the FPSCR. The eight DFP rounding modes are encoded in the DRN field as specified in the table below.

<table>
<thead>
<tr>
<th>DRN</th>
<th>Rounding Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>Round to Nearest, Ties to Even</td>
</tr>
<tr>
<td>001</td>

</tbody>
</table>

**Figure 71. Encoding of DFP Rounding-Mode Control (DRN)**

For the quantum-adjustment, a 2-bit immediate field, called **RMC** (*Rounding Mode Control*), in the instruction specifies the rounding mode used. The RMC field may contain a primary encoding or a secondary encoding. For **Quantize**, **Quantize Immediate**, and **Reround**, the RMC field contains the primary encoding. For **Round to FP Integer** the field contains either encoding, depending on the setting of a RMC-encoding-selection bit. The following tables define the primary encoding and the secondary encoding.

<table>
<thead>
<tr>
<th>Primary RMC</th>
<th>Rounding Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Round to nearest, ties to even</td>

### 5.5.3 Formation of Final Result

An ideal exponent is defined for each DFP instruction that returns a DFP data operand.

#### 5.5.3.1 Use of Ideal Exponent

For all DFP operations,
- if the rounded intermediate result has only one form, then that form is delivered as the final result.
- if the rounded intermediate result has redundant forms and is exact, then the form with the exponent closest to the ideal exponent is delivered.
- if the rounded intermediate result has redundant forms and is inexact, then the form with the smallest exponent is delivered.

The following table specifies the ideal exponent for each instruction.

<table>
<thead>
<tr>
<th>Operations</th>
<th>Ideal Exponent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add</td>
<td>$\min(E(FRA), E(FRB))$</td>
</tr>
<tr>
<td>Subtract</td>
<td>$\min(E(FRA), E(FRB))$</td>
</tr>
<tr>

<tr>
<td>Insert Biased Exponent</td>
<td>$E(FRA)$</td>
</tr>
</tbody>
</table>

Notes:
- $E(x)$ - exponent of the DFP operand in register $x$.

**Figure 74. Summary of Ideal Exponents**
5.5.4 Arithmetic Operations

Four arithmetic operations are provided: Add, Subtract, Multiply, and Divide.

5.5.4.1 Sign of Arithmetic Result

The following rules govern the sign of an arithmetic operation when the operation does not yield an exception. They apply even when the operands or results are zeros or infinities.

- The sign of the result of an add operation is the sign of the source operand having the larger absolute value. If both source operands have the same sign, the sign of the result of an add operation is the same as the sign of the source operands. When the sum of two operands with opposite signs is exactly zero, the sign of the result is positive in all rounding modes except Round toward -∞, in which case the sign is negative.
- The sign of the result of the subtract operation x - y is the same as the sign of the result of the add operation x + (-y).
- The sign of the result of a multiply or divide operation is the exclusive-OR of the signs of the source operands.

5.5.5 Compare Operations

Two sets of instructions are provided for comparing numerical values: Compare Ordered and Compare Unordered. In the absence of NaNs, these instructions work the same. These instructions work differently when either of the followings is true:

1. At least one source operand of the instruction is an SNaN and the invalid-operation exception is disabled.
2. When there is no SNaN in any source operand, at least one source operand of the instruction is a QNaN.

In case 1, Compare Unordered recognizes an invalid-operation exception and sets the VXSNAN flag, but Compare Ordered recognizes the exception and sets both the VXSNAN and VXVC flags. In case 2, Compare Unordered does not recognize an exception, but Compare Ordered recognizes an invalid-operation exception and sets the VXVC flag.

For finite numbers, comparisons are performed on values, that is, all redundant forms of a DFP number are treated equal.

Comparisons are always exact and cannot cause an inexact exception.

Comparison ignores the sign of zero, that is, +0 equals -0.

Infinities with like sign compare equal, that is, +∞ equals +∞, and -∞ equals -∞.

A NaN compares as unordered with any other operand, whether a finite number, an infinity, or another NaN, including itself.

Execution of a compare instruction always completes, regardless of whether any DFP exception occurs or not, and whether the exception is enabled or not.

5.5.6 Test Operations

Four kinds of test operations are provided: Test Data Class, Test Data Group, Test Exponent, and Test Significance.

The Test Data Class instruction examines the contents of a source operand and determines if the operand is one of the specified data classes. The test result and the sign of the source operand are indicated in the FPSCR field and CR field BF.

The Test Data Group instruction examines the contents of a source operand and determines if the operand is one of the specified data groups. The test result and the sign of the source operand are indicated in the FPCC field and CR field BF.

The Test Exponent instruction compares the exponent of the two source operands. The test operation ignores the sign and significand of operands. Infinities compare equal, and NaNs compare equal. The test result is indicated in the FPCC field and CR field BF.

Execution of a test instruction does not cause any DFP exception.

5.5.7 Quantum Adjustment Operations

Four kinds of quantum-adjustment operations are provided: Quantize, Quantize Immediate, Reround, and Round To FP Integer. Each of them has an immediate field which specifies whether the rounding mode in FPSCR or a different one is to be used.

The Quantize instruction is used to adjust a DFP number to the form that has the specified target exponent. The Quantize Immediate instruction is similar to the Quantize instruction, except that the target exponent is specified in a 5-bit immediate field as a signed binary integer and has a limited range.

The Reround instruction is used to simulate a DFP operation of a precision other than that of DFP Long or DFP Extended. For the Reround instruction to produce
a result which accurately reflects that which would have resulted from a DFP operation of the desired precision $d$ in the range $1:33$ inclusively, the following conditions must be met:

- The precision of the preceding DFP operation must be at least one digit larger than $d$.
- The rounding mode used by the preceding DFP operation must be round-to-prepare-for-shorter-precision.

The Round To FP Integer instruction is used to round a DFP number to an integer value of the same format. The target exponent is implicitly specified, and is greater than or equal to zero.

### 5.5.8 Conversion Operations

There are two kinds of conversion operations: data-format conversion and data-type conversion.

#### 5.5.8.1 Data-Format Conversion

The instructions Convert To DFP Long and Convert To DFP Extended convert DFP operands to wider formats; the instructions Round To DFP Short and Round To DFP Long convert DFP operands to narrower formats.

When converting a finite number to a wider format, the result is exact. When converting a finite number to a narrower format, the source operand is rounded to the target-format precision, which is specified by the instruction, not by the target register size.

When converting a finite number, the ideal exponent of the result is the source exponent.

Conversion of an infinity or NaN to a different format does not preserve the source combination field. Let $N$ be the width of the target format’s combination field.

- When the result is an infinity or a QNaN, the contents of the rightmost $N-5$ bits of the $N$-bit target combination field are set to zero.
- When the result is an SNaN, bit 5 of the target format’s combination field is set to one and the rightmost $N-6$ bits of the $N$-bit target combination field are set to zero.

When converting a NaN to a wider format or when converting an infinity from DFP Short to DFP Long, digits in the source trailing significand field are reencoded using the preferred DPD codes with sufficient zeros appended on the left to form the target trailing significand field. When converting a NaN to a narrower format or when converting an infinity from DFP Long to DFP Short, the appropriate number of leftmost digits of the source trailing significand field are removed and the remaining digits of the field are reencoded using the preferred DPD codes to form the target trailing significand field.

When converting an infinity between DFP Long and DFP Extended, a default infinity with the same sign is produced.

When converting an SNaN between DFP Short and DFP Long, it is converted to an SNaN without causing an invalid-operation exception. When converting an SNaN between DFP Long and DFP Extended, the invalid-operation exception occurs; if the invalid-operation exception is disabled, the result is converted to the corresponding QNaN.

#### 5.5.8.2 Data-Type Conversion

The instructions Convert From Fixed and Convert To Fixed are provided to convert a number between the DFP data type and the signed 64-bit binary-integer data type.

Conversion of a signed 64-bit binary integer to a DFP Extended number is always exact.

Conversion of a DFP number to a signed 64-bit binary integer results in an invalid-operation exception when the converted value does not fit into the target format, or when the source operand is an infinity or NaN. When the exception is disabled, the most positive integer is returned if the source operand is a positive number or $+\infty$, and the most negative integer is returned if the source operand is a negative number, $-\infty$, or NaN.

### 5.5.9 Format Operations

The format instructions are provided to facilitate composing or decomposing a DFP number, and consist of Encode BCD To DPD, Decode DPD To BCD, Extract Biased Exponent, Insert Biased Exponent, Shift Significand Left Immediate, and Shift Significand Right Immediate. A source operand of SNaN does not cause an invalid-operation exception, and an SNaN may be produced as the target operand.

### 5.5.10 DFP Exceptions

This architecture defines the following DFP exceptions:

- Invalid Operation Exception
  - SNaN
  - $\infty \times \infty$
  - $\infty \div \infty$
  - $0 \div 0$
  - Inexact Exception
  - Invalid Compare
  - Invalid Conversion
- Zero Divide Exception
- Overflow Exception
- Underflow Exception
- Inexact Exception

These exceptions may occur during execution of a DFP instruction.
Each DFP exception, and each category of the Invalid Operation Exception, has an exception status bit in the FPSCR. In addition, each DFP exception has a corresponding enable bit in the FPSCR. The exception status bit indicates occurrence of the corresponding exception. If an exception occurs, the corresponding enable bit governs the result produced by the instruction and, in conjunction with the fE0 and fE1 bits (see the discussion of fE0 and fE1 below), whether and how the system floating-point enabled exception error handler is invoked. (In general, the enabling specified by the enable bit is of invoking the system error handler, not of permitting the exception to occur. The occurrence of an exception depends only on the instruction and its source operands, not on the setting of any control bits. The only deviation from this general rule is that the occurrence of an Underflow Exception may depend on the setting of the enable bit.)

A single instruction, other than mtfsfi or mtfsf, may set more than one exception bit only in the following cases:

- Inexact Exception may be set with Overflow Exception.
- Inexact Exception may be set with Underflow Exception.
- Invalid Operation Exception (SNaN) may be set with Invalid Operation Exception (Invalid Compare) for Compare Ordered instructions
- Invalid Operation Exception (SNaN) may be set with Invalid Operation Exception (Invalid Conversion) for Convert To Fixed instructions.

When an exception occurs the instruction execution may be completed or partially completed, depending on the exception and the operation.

For all instructions, except for the Compare and Test instructions, the following exceptions cause the instruction execution to be partially completed. That is, setting of CR field 1 (when RC=1) and exception status flags is performed, but no result is stored into the target FPR or FPR pair. For Compare and Test instructions, instruction execution is always completed, regardless of whether any DFP exception occurs or not, and whether the exception is enabled or not.

- Enabled Invalid Operation
- Enabled Zero Divide

For the remaining kinds of exceptions, instruction execution is completed, a result, if specified by the instruction, is generated and stored into the target FPR or FPR pair, and appropriate status flags are set. The result may be a different value for the enabled and disabled conditions for some of these exceptions. The kinds of exceptions that deliver a result in target FPR are the following:

- Disabled Invalid Operation
- Disabled Zero Divide
- Disabled Overflow
- Disabled Underflow
- Disabled Inexact
- Enabled Overflow
- Enabled Underflow
- Enabled Inexact

Subsequent sections define each of the DFP exceptions and specify the action that is taken when they are detected.

The IEEE standard specifies the handling of exceptional conditions in terms of “traps” and “trap handlers”. In this architecture, a FPSCR exception enable bit of 1 causes generation of the result value specified in the IEEE standard for the “trap enabled” case: the expectation is that the exception will be detected by software, which will revise the result. A FPSCR exception enable bit of 0 causes generation of the “default result” value specified for the “trap disabled” (or “no trap occurs” or “trap is not implemented”) case: the expectation is that the exception will not be detected by software, which will simply use the default result. The result to be delivered in each case for each exception is described in the sections below.

The IEEE default behavior when an exception occurs is to generate a default value and not to notify software. In this architecture, if the IEEE default behavior when an exception occurs is desired for all exceptions, all FPSCR exception enable bits should be set to zero and Ignore Exceptions Mode (see below) should be used. In this case the system floating-point enabled exception error handler is not invoked, even if DFP exceptions occur: software can inspect the FPSCR exception bits if necessary, to determine whether exceptions have occurred.

In this architecture, if software is to be notified that a given kind of exception has occurred, the corresponding FPSCR exception enable bit must be set to one and a mode other than Ignore Exceptions Mode must be used. In this case the system floating-point enabled exception error handler is invoked if an enabled DFP exception occurs. The system floating-point enabled exception error handler is also invoked if a Move To FPSCR instruction causes an exception bit and the corresponding enable bit both to be 1; the Move To FPSCR instruction is considered to cause the enabled exception.

The fE0 and fE1 bits control whether and how the system floating-point enabled exception error handler is invoked if an enabled DFP exception occurs. The location of these bits and the requirements for altering them are described in Book III, Power ISA Operating Environment Architecture. (The system floating-point enabled exception error handler is never invoked...
because of a disabled DFP exception.) The effects of the four possible settings of these bits are as follows.

<table>
<thead>
<tr>
<th>FE0</th>
<th>FE1</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Ignore Exceptions Mode</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Imprecise Nonrecoverable Mode</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Imprecise Recoverable Mode</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Precise Mode</td>
</tr>
</tbody>
</table>

In all cases, the question of whether a DFP result is stored, and what value is stored, is governed by the FPSCR exception enable bits, as described in subsequent sections, and is not affected by the value of the FE0 and FE1 bits.

In all cases in which the system floating-point enabled exception error handler is invoked, all instructions before the instruction at which the system floating-point enabled exception error handler has been executed, and no instruction after the instruction at which the system floating-point enabled exception error handler is invoked has begun execution. (Recall that, for the two Imprecise modes, the instruction at which the system floating-point enabled exception error handler is invoked need not be the instruction that caused the exception.) The instruction at which the system floating-point enabled exception error handler is invoked has not been executed unless it is the excepting instruction, in which case it has been executed if the exception is not among those listed on page 197 as suppressed.

**Programming Note**

In the ignore and both imprecise modes, a Floating-Point Status and Control Register instruction can be used to force any exceptions, due to instructions initiated before the Floating-Point Status and Control Register instruction, to be recorded in the FPSCR. (This forcing is superfluous for Precise Mode.)

In either of the Imprecise modes, a Floating-Point Status and Control Register instruction can be used to force any invocations of the system floating-point enabled exception error handler, due to instructions initiated before the Floating-Point Status and Control Register instruction, to occur. (This forcing has no effect in Ignore Exceptions Mode, and is superfluous for Precise Mode.)

In order to obtain the best performance across the widest range of implementations, the programmer should obey the following guidelines.

- If the IEEE default results are acceptable to the application, Ignore Exceptions Mode should be used with all FPSCR exception enable bits set to zero.
- If the IEEE default results are not acceptable to the application, Imprecise Nonrecoverable Mode should be used, or Imprecise Recoverable Mode if recoverability is needed, with FPSCR exception enable bits set to one for those exceptions for which the system floating-point enabled exception error handler is to be invoked.
- Ignore Exceptions Mode should not, in general, be used when any FPSCR exception enable bits are set to one.
- Precise Mode may degrade performance in some implementations, perhaps substantially, and therefore should be used only for debugging and other specialized applications.

### 5.5.10.1 Invalid Operation Exception

**Definition**

An Invalid Operation Exception occurs when an operand is invalid for the specified DFP operation. The invalid DFP operations are:

- Any DFP operation on a signaling NaN (SNaN), except for Test, Round To DFP Short, Convert To DFP Long, Decode DPD To BCD, Extract Biased Exponent, Insert Biased Exponent, Shift Significand Left Immediate, and Shift Significand Right Immediate
For add or subtract operations, magnitude subtraction of infinities \((\infty + -\infty)\) and Invalid Operation Exception is enabled (\(VE=1\)) and Invalid Operation occurs, the following actions are taken:

1. **One or two Invalid Operation Exceptions are set:**
   - \(VXSNAN\) (if SNaN)
   - \(VXXS\) (if \(\infty \times \infty\))
   - \(VXDI\) (if \(\infty \div \infty\))
   - \(VXZDZ\) (if \(0 \div 0\))
   - \(VXIMZ\) (if \(\infty \times 0\))
   - \(VXVC\) (if invalid comp)
   - \(VXCVI\) (if invalid conversion)

2. **If the operation is an arithmetic, quantum-adjustment, conversion, or format:**
   - The target FPR is unchanged.
   - \(FR\) and \(FI\) are set to zero.
   - \(FPFR\) is set to indicate the class of the result (Quiet NaN)

3. **If the operation is a compare:**
   - \(FR\), \(FI\), and \(C\) are unchanged.
   - \(FPCC\) is set to reflect unordered.

When Invalid Operation Exception is disabled (\(VE=0\)) and Invalid Operation occurs, the following actions are taken:

1. One or two Invalid Operation Exceptions are set:
   - \(VXSNAN\) (if SNaN)
   - \(VXXS\) (if \(\infty \times \infty\))
   - \(VXDI\) (if \(\infty \div \infty\))
   - \(VXZDZ\) (if \(0 \div 0\))
   - \(VXIMZ\) (if \(\infty \times 0\))
   - \(VXVC\) (if invalid comp)
   - \(VXCVI\) (if invalid conversion)

2. **If the operation is an arithmetic, quantum-adjustment, Round to DFP Long, Convert to DFP Extended, or format:**
   - The target FPR is set to a Quiet NaN.
   - \(FR\) and \(FI\) are set to zero.
   - \(FPFR\) is set to indicate the class of the result (Quiet NaN)

3. **If the operation is a Convert To Fixed:**
   - The target FPR is set as follows:
     - \(FRT\) is set to the most positive 64-bit binary integer if the operand in FRB is a positive or \(+\infty\), and to the most negative 64-bit binary integer if the operand in FRB is a negative number, \(-\infty\), or NaN.
     - \(FR\) and \(FI\) are set to zero.
     - \(FPFR\) is unchanged.

4. **If the operation is a compare:**
   - \(FR\), \(FI\), and \(C\) are unchanged.
   - \(FPCC\) is set to reflect unordered.

### 5.5.10.2 Zero Divide Exception

**Definition**

A Zero Divide Exception occurs when a Divide instruction is executed with a zero divisor value and a finite nonzero dividend value.

**Action**

The action to be taken depends on the setting of the Zero Divide Exception Enable bit of the FPSCR.

When Zero Divide Exception is enabled (\(ZE=1\)) and Zero Divide occurs, the following actions are taken:

1. **Zero Divide Exception is set:**
   \(ZE \leftarrow 1\)

2. **The target FPR is unchanged:**

3. **\(FR\) and \(FI\) are set to zero:**

4. **\(FPFR\) is unchanged:**

When Zero Divide Exception is disabled (\(ZE=0\)) and Zero Divide occurs, the following actions are taken:

1. **Zero Divide Exception is set:**
   \(ZE \leftarrow 1\)

2. **The target FPR is set to \(\pm\infty\), where the sign is determined by the XOR of the signs of the operands:**

---

**Programming Note**

In addition, an Invalid Operation Exception occurs if software explicitly requests this by executing an \(mtfsi\), \(mtfsf\), or \(mtfsb1\) instruction that sets \(VXSOFT\) to 1 (Software Request). The purpose of \(VXSOFT\) is to allow software to cause an Invalid Operation Exception for a condition that is not necessarily associated with the execution of a DFP instruction. For example, it might be set by a program that computes a square root, if the source operand is negative.
3. \( FR \) and \( FL \) are set to zero
4. \( FPRF \) is set to indicate the class and sign of the result (±∞)

### 5.5.10.3 Overflow Exception

**Definition**

An overflow exception occurs whenever the target format’s largest finite number is exceeded in magnitude by what would have been the rounded result if the exponent range were unbounded.

**Action**

Except for Reround, the following describes the handling of the IEEE overflow exception condition. The Reround operation does not recognize an overflow exception condition.

The action to be taken depends on the setting of the Overflow Exception Enable bit of the FPSCR.

When Overflow Exception is enabled (OE=1) and overflow occurs, the following actions are taken:

1. Overflow Exception is set \( OX \) ← 1
2. The infinitely precise result is divided by \( 10^{\alpha} \). That is, the exponent adjustment \( \alpha \) is subtracted from the exponent. This is called the *wrapped result*. The exponent adjustment for all operations, except for Round To DFP Short and Round To DFP Long, is 576 for DFP Long and 9216 for DFP Extended. For Round To DFP Short and Round To DFP Long, the exponent adjustment is 192 for the source format of DFP Long and 3072 for the source format of DFP Extended.
3. The wrapped result is rounded to the target-format precision. This is called the *wrapped rounded result*.
4. If the wrapped rounded result has only one form, it is the delivered result. If the wrapped rounded result has redundant forms and is exact, the result of the form that has the exponent closest to the wrapped ideal exponent is returned. If the wrapped rounded result has redundant forms and is inexact, the result of the form that has the smallest exponent is returned. The wrapped ideal exponent is the result of subtracting the exponent adjustment from the ideal exponent.
5. \( FPRF \) is set to indicate the class and sign of the result (± Normal Number)

When Overflow Exception is disabled (OE=0) and overflow occurs, the following actions are taken:

1. Overflow Exception is set \( OX \) ← 1
2. Inexact Exception is set \( XX \) ← 1
3. The result is determined by the rounding mode and the sign of the intermediate result as follows.

<table>
<thead>
<tr>
<th>Rounding Mode</th>
<th>Sign of intermediate result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Round to Nearest, Ties to Even</td>
<td>+∞</td>
</tr>
<tr>
<td>Round toward 0</td>
<td>( +N_{\text{long}} )</td>
</tr>
<tr>
<td>Round toward +∞</td>
<td>+∞</td>
</tr>
<tr>
<td>Round toward -∞</td>
<td>( -N_{\text{long}} )</td>
</tr>
<tr>
<td>Round to Nearest, Ties away from 0</td>
<td>+∞</td>
</tr>
<tr>
<td>Round to Nearest, Ties toward 0</td>
<td>+∞</td>
</tr>
<tr>
<td>Round away from 0</td>
<td>+∞</td>
</tr>
<tr>
<td>Round to prepare for shorter precision</td>
<td>( +N_{\text{long}} )</td>
</tr>
</tbody>
</table>

**Figure 75. Overflow Results When Exception Is Disabled**

4. The result is placed into the target FPR
5. \( FR \) is set to one if the returned result is ±∞, and is set to zero if the returned result is ±\( N_{\text{long}} \).
6. \( FL \) is set to one
7. \( FPRF \) is set to indicate the class and sign of the result (±∞ or ± Normal Number)

### 5.5.10.4 Underflow Exception

**Definition**

Except for Reround, the following describes the handling of the IEEE underflow exception condition. The Reround operation does not recognize an underflow exception condition.

The Underflow Exception is defined differently for the enabled and disabled states. However, a tininess condition is recognized in both states when a result computed as though both the precision and exponent range were unbounded would be nonzero and less than the target format’s smallest normal number, \( N_{\text{min}} \), in magnitude.

Unless otherwise defined in the instruction description, an underflow exception occurs as follows:

- **Enabled:**
  - When the tininess condition is recognized.
- **Disabled:**
  - When the tininess condition is recognized and when the delivered result value differs from what would have been computed were both the precision and the exponent range unbounded.
**Action**

The action to be taken depends on the setting of the Underflow Exception Enable bit of the FPSCR.

When Underflow Exception is enabled (UE=1) and underflow occurs, the following actions are taken:

1. Underflow Exception is set $UX \leftarrow 1$
2. The infinitely precise result is multiplied by $10^\alpha$. That is, the exponent adjustment $\alpha$ is added to the exponent. This is called the wrapped result. The exponent adjustment for all operations, except for Round To DFP Short and Round To DFP Long, is 576 for DFP Long and 9216 for DFP Extended. For Round To DFP Short and Round To DFP Long, the exponent adjustment is 192 for the source format of DFP Long and 3072 for the source format of DFP Extended.
3. The wrapped result is rounded to the target-format precision. This is called the wrapped rounded result.
4. If the wrapped rounded result has only one form, it is the delivered result. If the wrapped rounded result has redundant forms and is exact, the result of the form that has the exponent closest to the wrapped ideal exponent is returned. If the wrapped rounded result has redundant forms and is inexact, the result of the form that has the smallest exponent is returned. The wrapped ideal exponent is the result of adding the exponent adjustment to the ideal exponent.
5. $FPRF$ is set to indicate the class and sign of the result ($\pm$ Normal number)

When Underflow Exception is disabled (UE=0) and underflow occurs, the following actions are taken:

1. Underflow Exception is set $UX \leftarrow 1$
2. The infinitely precise result is rounded to the target-format precision.
3. The rounded result is returned. If this result has redundant forms, the result of the form that is closest to the ideal exponent is returned.
4. $FPRF$ is set to indicate the class and sign of the result ($\pm$ Normal number, $\pm$ Subnormal Number, or $\pm$ Zero)

**5.5.10.5 Inexact Exception**

**Definition**

Except for Round to FP Integer Without Inexact, the following describes the handling of the IEEE inexact exception condition. The Round to FP Integer Without Inexact does not recognize an inexact exception condition.

An Inexact Exception occurs when either of two conditions occur during rounding:

1. The delivered result differs from what would have been computed were both the precision and exponent range unbounded.
2. The rounded result overflows and Overflow Exception is disabled.

**Action**

The action to be taken does not depend on the setting of the Inexact Exception Enable bit of the FPSCR.

When Inexact Exception occurs, the following actions are taken:

1. Inexact Exception is set $XX \leftarrow 1$
2. The rounded or overflowed result is placed into the target FPR
3. $FPRF$ is set to indicate the class and sign of the result

**Programming Note**

In some implementations, enabling Inexact Exceptions may degrade performance more than does enabling other types of floating-point exception.
### 5.5.11 Summary of Normal Rounding And Range Actions

Figure 76 and Figure 77 summarize rounding and range actions, with the following exceptions:

- The *Reround* operation recognizes neither an underflow nor an overflow exception.
- The *Round to FP Integer Without Inexact* operation does not recognize the inexact operation exception.

#### Figure 76. Rounding and Range Actions (Part 1)

<td>(+\infty)</td>
</tr>
</tbody>
</table>

#### Explanation:

- This situation cannot occur.
- The normal result \(r\) is considered to have been incremented.
- The rounded value, in the extreme case, may be \(Nmin\). In this case, the exception conditions are underflow, inexact, and incremented.
- The value derived when the precise result \(v\) is rounded to the destination’s precision, including both bounded precision and bounded exponent range.
- The value derived when the precise result \(v\) is rounded to the destination’s precision, but assuming an unbounded exponent range.
- This is the returned value when neither overflow nor underflow is enabled.
- Precise result before rounding, assuming unbounded precision and an unbounded exponent range. For data-format conversion operations, \(v\) is the source value.
- Smallest (in magnitude) representable subnormal number in the target format.
- The result \(r\) of the exact-zero-difference case applies only to ADD and SUBTRACT with both source operands having opposite signs. (For ADD and SUBTRACT, when both source operands have the same sign, the sign of the zero result is the same sign as the sign of the source operands.)
- Largest (in magnitude) representable finite number in the target format.
- Smallest (in magnitude) representable normalized number in the target format.
- Round away from 0.
- Round to Prepare for Shorter Precision.
- Round to Nearest, Ties from away from 0.
- Round to Nearest, Ties to even.
- Round to Nearest, Ties toward 0.
- Round toward \(+\infty\).
- Round toward \(-\infty\).
- Round toward 0.

</tbody>
</table>

Explanation:

— The results do not depend on this condition.
  1 This condition is true by virtue of the state of some condition to the left of this column.
  * Rounding sets only FI and FR. Setting of OX, XX, or UX is part of the exception actions. They are listed here for reference.
  β Wrap adjust, which depends on the type of operation and operand format. For all operations except Round to DFP Short and Round to DFP Long, the wrap adjust depends on the target format: β = 10^α, where α is 576 for DFP Long, and 9216 for DFP Extended. For Round to DFP Short and Round to DFP Long, the wrap adjust depends on the source format: β = 10^α where α is 192 for DFP Long and 3072 for DFP Extended.
  q The value derived when the precise result v is rounded to destination’s precision, but assuming an unbounded exponent range.
  r The result as defined in Part 1 of this figure.
  v Precise result before rounding, assuming unbounded precision and unbounded exponent range.
  FI Floating-Point-Fraction-Inexact status flag, FI. This status flag is non-sticky.
  FR Floating-Point-Fraction-Rounded status flag, FR.
  OX Floating-Point Overflow Exception status flag, OX.
  TO The system floating-point enabled exception error handler is invoked for the overflow exception if FE0 and FE1 are set to any mode other than the ignore-exception mode.
  TU The system floating-point enabled exception error handler is invoked for the underflow exception if FE0 and FE1 are set to any mode other than the ignore-exception mode.
  TX The system floating-point enabled exception error handler is invoked for the inexact exception if FE0 and FE1 are set to any mode other than the ignore-exception mode.
  T[x] The value x is placed at the target operand location.
  TW(x) The wrapped rounded result x is placed at the target operand location. For all operations except data format conversions, the wrapped rounded result is in the same format and length as normal results at the target location. For data format conversions, the wrapped rounded result is in the same format and length as the source, but rounded to the target-format precision.
  UX Floating-Point-Underflow-Exception status bit.
  XX Floating-Point Inexact exception status bit. The flag is a sticky version of FI. When FI is set to a new value, the new value of XX is set to the result of ORing the old value of XX with the new value of FI.

Figure 77. Rounding and Range Actions (Part 2)
5.6 DFP Instruction Descriptions

The following sections describe the DFP instructions. When a 128-bit operand is used, it is held in a FPR pair and the instruction mnemonic uses a letter “q” to mean the quad-precision operation. Note that in the following descriptions, \( \text{FRX}_p \) denotes a FPR pair and must address an even-odd pair. If the \( \text{FRX}_p \) field specifies an odd-numbered register, then the instruction form is invalid. The notation \( \text{FRX}[p] \) means either a FPR, \( \text{FRX} \), or a FPR pair, \( \text{FRX}_p \).

For DFP instructions, if a DFP operand is returned, the trailing significand field of the target operand is encoded using preferred DPD codes.

5.6.1 DFP Arithmetic Instructions

All DFP arithmetic instructions are X-form instructions. They all set the FI and FR status flags, and also set the FPRF field. Furthermore, they all have an ideal exponent assigned and employ the record bit (Rc).

The arithmetic instructions consist of Add, Divide, Multiply, and Subtract.
**DFP Add X-form**

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
59 & FRT & FRA & FRB & 2 & Rc \\
\hline
0 & 6 & 11 & 16 & 21 & 31 \\
\hline
\end{array}
\]

**DFP Add Quad X-form**

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
63 & FRTp & FRAp & FRBp & 2 & Rc \\
\hline
0 & 6 & 11 & 16 & 21 & 31 \\
\hline
\end{array}
\]

The DFP operand in \( FRA[p] \) is added to the DFP operand in \( FRB[p] \).

The result is rounded to the target-format precision under control of \( DRN \) (bits 29:31 of the FPSCR). An appropriate form of the rounded result is selected based on the ideal exponent and is placed in \( FRT[p] \). The ideal exponent is the smaller exponent of the two source operands.

Figure 78 summarizes the actions for Add. Figure 78 does not include the setting of \( FPRF \). \( FPRF \) is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

\( dadd[q][] \) are treated as *Floating-Point* instructions in terms of resource availability.

**Special Registers Altered:**

- \( FPRF \)
- \( FR \)
- \( FI \)
- \( FX \)
- \( OX \)
- \( UX \)
- \( XX \)
- \( VXSNAN \)
- \( VXISI \)
- \( CR1 \) (if \( Rc=1 \))

**DFP Subtract X-form**

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
59 & FRT & FRA & FRB & 514 & Rc \\
\hline
0 & 6 & 11 & 16 & 21 & 31 \\
\hline
\end{array}
\]

**DFP Subtract Quad X-form**

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
63 & FRTp & FRAp & FRBp & 514 & Rc \\
\hline
0 & 6 & 11 & 16 & 21 & 31 \\
\hline
\end{array}
\]

The DFP operand in \( FRB[p] \) is subtracted from the DFP operand in \( FRA[p] \).

The result is rounded to the target-format precision under control of \( DRN \) (bits 29:31 of the FPSCR). An appropriate form of the rounded result is selected based on the ideal exponent and is placed in \( FRT[p] \). The ideal exponent is the smaller exponent of the two source operands.

The execution of Subtract is identical to that of Add, except that the operand in \( FRB \) participates in the operation with its sign bit inverted. See Figure 78. The table does not include the setting of \( FPRF \). \( FPRF \) is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

\( dsub[q][] \) are treated as *Floating-Point* instructions in terms of resource availability.

**Special Registers Altered:**

- \( FPRF \)
- \( FR \)
- \( FI \)
- \( FX \)
- \( OX \)
- \( UX \)
- \( XX \)
- \( VXSNAN \)
- \( VXISI \)
- \( CR1 \) (if \( Rc=1 \))
Operand a in FRA[p] is | Actions for Add \((a + b)\) when operand b in FRB[p] is
<table>
<thead>
<tr>
<th>(\infty)</th>

<td>VXSNAN: U(a)</td>
<td>VXSNAN: U(a)</td>
<td>VXSNAN: U(a)</td>
<td>VXSNAN: U(a)</td>
</tr>
</tbody>
</table>

Explanation:
- \(a+b\) The value a added to b, rounded to the target-format precision and returned in the appropriate form. (See Section 5.5.11 on page 203)
- \(+dINF\) Default plus infinity.
- \(-dINF\) Default minus infinity.
- \(dNaN\) Default quiet NaN.
- \(F\) All finite numbers, including zeros.
- \(P(x)\) The QNaN of operand x is propagated and placed in FRT[p].
- \(S(x)\) The value x is placed in FRT[p] with the sign set by the rules of algebra. When the source operands have the same sign, the sign of the result is the same as the sign of the operands, including the case when the result is zero. When the operands have opposite signs, the sign of a zero result is positive in all rounding modes, except round toward \(-\infty\), in which case, the sign is minus.
- \(T(x)\) The value x is placed in FRT[p].
- \(U(x)\) The SNaN of operand x is converted to the corresponding QNaN and placed in FRT[p].
- VXISI: Floating-Point Invalid Operation (Infinity - Infinity) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 199.)
- VXSNAN: Floating-Point Invalid Operation (SNaN) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 199.)
DFP Multiply X-form

\[ \text{dmul} \text{ FRT,FRA,FRB } (R_c=0) \]
\[ \text{dmul.} \text{ FRT,FRA,FRB } (R_c=1) \]

DFP Multiply Quad X-form

\[ \text{dmulq} \text{ FRTp,FRAp,FRBp } (R_c=0) \]
\[ \text{dmulq.} \text{ FRTp,FRAp,FRBp } (R_c=1) \]

The DFP operand in \( \text{FRA}[p] \) is multiplied by the DFP operand in \( \text{FRB}[p] \).

The result is rounded to the target-format precision under control of \( \text{DRN} \) (bits 29:31 of the FPSCR). An appropriate form of the rounded result is selected based on the ideal exponent and is placed in \( \text{FRT}[p] \). The ideal exponent is the sum of the two exponents of the source operands.

The content is divided into sections about DFP Multiply X-form and DFP Multiply Quad X-form. Each section includes a table that lists the actions for Multiply, with columns for operands in \( \text{FRA}[p] \) and \( \text{FRB}[p] \), and actions for Multiply \( (a \times b) \) when operand \( b \) in \( \text{FRB}[p] \) is.

The table contains the following columns:
- **Operand a** in \( \text{FRA}[p] \)
- **Actions for Multiply** \( (a \times b) \) when operand \( b \) in \( \text{FRB}[p] \) is
- 0
- \( \infty \)
- \( \text{QNaN} \)
- \( \text{SNaN} \)

Each row in the table details the actions for different operations involving \( a \times b \) and \( b \) in \( \text{FRB}[p] \). The actions include:
- \( S(a \times b) \)
- \( S(a \times b) \text{ VXiNZ: T(dNaN)} \)
- \( S(a \times b) \text{ P(b)} \)
- \( VXSnan: U(b) \)
- \( P(a) \)
- \( P(a) \text{ VXiSNAN: U(a)} \)
- \( P(a) \text{ VXSnan: U(a)} \)
- \( P(a) \text{ VXSnan: U(a)} \)

The explanation for each action is provided, such as:
- \( S(a \times b) \) means the value is placed in \( \text{FRT}[p] \).
- \( P(a) \text{ VXiSNAN: U(a)} \) means the SNaN of operand \( a \) is converted to the corresponding QNaN and placed in \( \text{FRT}[p] \).

Figure 79 summarizes the actions for Multiply. Figure 79 does not include the setting of \( \text{FPRF} \). \( \text{FPRF} \) is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

\[ \text{dmulq}[q][] \] are treated as Floating-Point instructions in terms of resource availability.

### Special Registers Altered:

- \( \text{FPRF FR FI} \)
- \( \text{FX OX UX XX VXSnan VXImZ CR1} \) \( (\text{if } R_c=1) \)

Figure 79. Actions: Multiply
DFP Divide X-form

\[ \text{ddiv} \quad \text{FRT,FRA,FRB} \quad \text{(Rc=0)} \]
\[ \text{ddiv.} \quad \text{FRT,FRA,FRB} \quad \text{(Rc=1)} \]

DFP Divide Quad X-form

\[ \text{ddivq} \quad \text{FRTp,FRAp,FRBp} \quad \text{(Rc=0)} \]
\[ \text{ddivq.} \quad \text{FRTp,FRAp,FRBp} \quad \text{(Rc=1)} \]

The DFP operand in \( \text{FRA}[p] \) is divided by the DFP operand in \( \text{FRB}[p] \).

The result is rounded to the target-format precision under control of the DRN (bits 29:31 of the FPSCR). An appropriate form of the rounded result is selected based on the ideal exponent and is placed in \( \text{FRT}[p] \).

The ideal exponent is the difference of subtracting the exponent of the divisor from the exponent of the dividend.

Table: Actions for Divide (\( a \div b \)) when operand \( b \) in \( \text{FRB}[p] \) is

<table>
<thead>
<tr>
<th>Operand ( a ) in ( \text{FRA}[p] ) is</th>
<th>( 0 )</th>

</tbody>
</table>

Explanation:
- \( a \div b \) The value \( a \) divided by \( b \), rounded to the target-format precision and returned in the appropriate form. (See Section 5.5.11 on page 203.)
- \( dINF \) Default infinity.
- \( dNaN \) Default quiet NaN.
- \( Fx \) Finite nonzero number (includes both normal and subnormal numbers).
- \( P(x) \) The QNaN of operand \( x \) is propagated and placed in \( \text{FRT}[p] \).
- \( S(x) \) The value \( x \) is placed in \( \text{FRT}[p] \) with the sign set to the exclusive-OR of the source-operand signs.
- \( T(x) \) The value \( x \) is placed in \( \text{FRT}[p] \).
- \( U(x) \) The SNaN of operand \( x \) is converted to the corresponding QNaN and placed in \( \text{FRT}[p] \).
- \( \text{VXI DI:} \) Floating-Point Invalid Operation (Infinity \( \div \) Infinity) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 199 for the exception actions.)
- \( \text{VXSNAN:} \) Floating-Point Invalid Operation (SNaN) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 199.)
- \( \text{VXZDZ:} \) Floating-Point Invalid Operation (Zero \( \div \) Zero) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 199.)
- \( \text{zt} \) True zero (zero significand and most negative exponent).
- \( Zx \) The Zero-Divide Exception occurs. The result is produced only when the exception is disabled (See Section 5.5.10.2 “Zero Divide Exception” on page 200.)
5.6.2 DFP Compare Instructions

The DFP compare instructions consist of the Compare Ordered and Compare Unordered instructions. The compare instructions do not provide the record bit. The comparison sets the designated CR field to indicate the result. FPCC is set in the same way.

The codes in the CR field BF and FPCC are defined for the DFP compare operations as follows.

<table>
<thead>
<tr>
<th>Bit Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

**Figure 82. Actions: Compare Ordered**
5.6.3 DFP Test Instructions

The DFP test instructions consist of the Test Data Class, Test Data Group, Test Exponent, and Test Significance instructions, and they do not provide the record bit. The test instructions set the designated CR field to indicate the result. The FPSCR\textsubscript{FPCC} is set in the same way.

**DFP Test Data Class Z22-form**

\[
\begin{array}{c|c|c|c|c|c|c}
59 & BF & FRA & DCM & 194 & \\
0 & 6 & 9 & 11 & 16 & 21 & \\
\end{array}
\]

**DFP Test Data Class Quad Z22-form**

\[
\begin{array}{c|c|c|c|c|c|c}
63 & BF & FRAp & DCM & 194 & \\
0 & 6 & 9 & 11 & 16 & 21 & \\
\end{array}
\]

Let the DCM (Data Class Mask) field specify one or more of the 6 possible data classes, where each bit corresponds to a specific data class.

<table>
<thead>
<tr>
<th>DCM Bit</th>
<th>Data Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Zero</td>
</tr>
<tr>
<td>1</td>
<td>Subnormal</td>
</tr>
<tr>
<td>2</td>
<td>Normal</td>
</tr>
<tr>
<td>3</td>
<td>Infinity</td>
</tr>
<tr>
<td>4</td>
<td>Quiet NaN</td>
</tr>
<tr>
<td>5</td>
<td>Signaling NaN</td>
</tr>
</tbody>
</table>

CR field BF and FPCC are set to indicate the sign of the DFP operand in FRA\textsubscript{p} and whether the data class of the DFP operand in FRA\textsubscript{p} matches any of the data classes specified by DCM.

<table>
<thead>
<tr>
<th>Field</th>
<th>Meaning</th>
</tr>

<tr>
<td>2</td>
<td>( k = 0 ) and ( k = \text{NSDb} )</td>
</tr>
<tr>
<td>3</td>
<td>( k &lt; \text{NSDb} )</td>
</tr>
</tbody>
</table>

**DFP Test Significance Quad X-form**

\[ \text{dtsstfq} \text{ BF,FRA,FRBp} \]

Let \( k \) be the contents of bits 58:63 of \( \text{FPR}[\text{FRA}] \) that specifies the reference significance.

For \( \text{dtsstf} \), let the value \( \text{NSDb} \) be the number of significant digits of the DFP value in \( \text{FPR}[\text{FRB}] \).

For \( \text{dtsstfq} \), let the value \( \text{NSDb} \) be the number of significant digits of the DFP value in \( \text{FPR}[\text{FRBp:FRBp+1}] \).

For this instruction, the number of significant digits of the value 0 is considered to be zero.

\( \text{NSDb} \) is compared to \( k \). The result of the compare is placed into CR field \( \text{BF} \) and the \( \text{FPCC} \) as follows.

- \( k \neq 0 \) and \( k < \text{NSDb} \) : \( \text{AeqB} \)
- \( k \neq 0 \) and \( k > \text{NSDb} \), or \( k = 0 \) : \( \text{AgtB} \)
- \( k = 0 \) and \( k = \text{NSDb} \) : \( \text{AltB} \)

**Actions for Test Significance**

<table>
<thead>
<tr>
<th>Relation of Value ( \text{NSDb} ) to Value ( k )</th>
<th>Action for ( \text{C}(k:\text{NSDb}) )</th>
</tr>
</thead>
<tbody>
<tr>

<td>10</td>
<td>16</td>
<td>21</td>
</tr>
</tbody>
</table>

Let the value UIM specify the reference significance.

For dtstsfi, let the value NSDb be the number of significant digits of the DFP value in FPR[FRB].

For dtstsfq, let the value NSDb be the number of significant digits of the DFP value in FPR[FRBp:FRBp+1].

For this instruction, the number of significant digits of the value 0 is considered to be zero.

NSDb is compared to UIM. The result of the compare is placed into CR field BF and the FPCC as follows.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>UIM ≠ 0 and UIM &lt; NSDb</td>
</tr>
<tr>
<td>1</td>

</table>

Figure 85. Actions: Test Significance
5.6.4 DFP Quantum Adjustment Instructions

The Quantum Adjustment operations consist of the Quantize, Quantize Immediate, Reround, and Round To FP Integer operations.

The Quantum Adjustment instructions are Z23-form instructions and have an immediate RMC (Rounding-Mode-Control) field, which specifies the rounding mode used. For Quantize, Quantize Immediate, and Reround, the RMC field contains the primary encoding. For Round to FP Integer, the field contains either primary or secondary encoding, depending on the setting of a RMC-encoding-selection bit. See Section 5.5.2 “Rounding Mode Specification” on page 195 for the definition of RMC encoding.

DFP Quantize Immediate Z23-form

dquai TE,FRT,FRB,RMC
\( (Rc=0) \)
dquai. TE,FRT,FRB,RMC
\( (Rc=1) \)

DFP Quantize Immediate Quad Z23-form

dquaiz TE,FRTp,FRBp,RMC
\( (Rc=0) \)
dquaiz. TE,FRTp,FRBp,RMC
\( (Rc=1) \)

The DFP operand in \( FRB[p] \) is converted and rounded to the form with the exponent specified by \( TE \) based on the rounding mode specified in the RMC field. \( TE \) is a 5-bit signed binary integer. The result of that form is placed in \( FRT[p] \). The sign of the result is the same as the sign of the operand in \( FRB[p] \). The ideal exponent is the exponent specified by \( TE \).

When the value of the operand in \( FRB[p] \) is greater than \((10^p-1) \times 10^{TE} \), where \( p \) is the format precision, an invalid operation exception is recognized.

When the delivered result differs in value from the operand in \( FRB[p] \), an inexact exception is recognized. No underflow exception is recognized by this operation, regardless of the value of the operand in \( FRB[p] \).

\( FPRF \) is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

\( dquaiz[q][] \) are treated as Floating-Point instructions in terms of resource availability.

Special Registers Altered:

FPRF & \quad FR \quad FI \\
FX & \quad XX \\
VXSNAN & \quad VXCVI \\
CR1 & \quad (if Rc=1)
\end{align*} \]
DFP Quantize Immediate can be used to adjust values to a form having the specified exponent in the range -16 to 15. If the adjustment requires the significand to be shifted left, then:

- if the result would cause overflow from the most significant digit, the result is a default QNaN;
- otherwise the result is the adjusted value (left shifted with matching exponent).

If the adjustment requires the significand to be shifted right, the result is rounded based on the value of the RMC field.

DFP Quantize Immediate can round a value to a specific number of fractional digits. Consider the computation of sales tax. Values expressed in U.S. dollars have 2 fractional digits, and sales tax rates typically have 3 fractional digits. The product of value and rate will yield 5 fractional digits. For example:

\[ 39.95 \times 0.075 = 2.99625 \]

This result needs to be rounded to the penny to compute the correct tax of $3.00.

The following sequence computes the sales tax assuming the pre-tax total is in FRA and the tax rate is in FRB. The DFP Quantize Immediate instruction rounds the product (FRA \times FRB) to 2 fractional digits (TE = -2) using Round to nearest, ties away from 0 (RMC = 2). The quantized and rounded result is placed in FRT.

```
dmul f0,FRA,FRB
dqua -2,FRT,f0,2
```
**DFP Quantize Z23-form**

\[ \text{dqua.} \quad \text{FRT, FRA, FRB, RMC} \quad (\text{Rc}=0) \]
\[ \text{dqua} \quad \text{FRT, FRA, FRB, RMC} \quad (\text{Rc}=1) \]

The DFP operand in register \( \text{FRB}[p] \) is converted and rounded to the form with the same exponent as that of the DFP operand in \( \text{FRA}[p] \) based on the rounding mode specified by \( \text{RMC} \). The sign of the result is the same as the sign of the operand in \( \text{FRB}[p] \). The ideal exponent is the exponent specified in \( \text{FRA}[p] \).

When the value of the operand in \( \text{FRB}[p] \) is greater than \( (10^p - 1) \times 10^{E_a} \), where \( p \) is the format precision and \( E_a \) is the exponent of the operand in \( \text{FRA}[p] \), an invalid operation exception is recognized.

When the delivered result differs in value from the operand in \( \text{FRB}[p] \), an inexact exception is recognized. No underflow exception is recognized by this operation, regardless of the value of the operand in \( \text{FRB}[p] \).

**Programming Note**

**DFP Quantize** can be used to adjust one DFP value (\( \text{FRB}[p] \)) to a form having the same exponent as a second DFP value (\( \text{FRA}[p] \)). If the adjustment requires the significand to be shifted left, then:
- if the result would cause overflow from the most significant digit, the result is a default QNaN;
- otherwise the result is the adjusted value (left shifted with matching exponent).

If the adjustment requires the significand to be shifted right, the result is rounded based on the value of \( \text{RMC} \). Figure 86 shows examples of these adjustments.

---

**DFP Quantize Quad Z23-form**

\[ \text{dqua}\text{q} \quad \text{FRTp, FRAp, FRBp, RMC} \quad (\text{Rc}=0) \]
\[ \text{dqua}\text{q} \quad \text{FRTp, FRAp, FRBp, RMC} \quad (\text{Rc}=1) \]

Figure 87 and Figure 88 summarize the actions. The tables do not include the setting of \( \text{FPRF} \). \( \text{FPRF} \) is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

\[ \text{dqua}[[q]] \] are treated as Floating-Point instructions in terms of resource availability.

</tbody>
</table>

**Explanation:**

* See next table.

- **dINF** Default infinity
- **dNaN** Default quiet NaN
- **Fn** Finite nonzero numbers (includes both subnormal and normal numbers)
- **P(x)** The QNaN of operand x is propagated and placed in FRT[p]
- **T(x)** The value x is placed in FRT[p]
- **U(x)** The SNaN of operand x is converted to the corresponding QNaN and placed in FRT[p].
- **VXCVI**: Floating-Point Invalid Operation (Invalid Conversion) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 199.)
- **VXSNAN**: Floating-Point Invalid Operation (SNaN) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 199.)

### Actions for Quantize when operand b in FRB[p] is

<table>
<thead>
<tr>
<th>Te &lt; Se</th>
<th>Actions for Quantize when operand b in FRB[p] is</th>
<th>0</th>
<th>Fn</th>
</tr>
</thead>

<tr>
<td>V0 ≤ (10^p - 1) \times 10^{Te}</td>
<td>E(0)</td>
<td>L(b)</td>
<td></td>
</tr>
</tbody>
</table>

**Explanation:**

- **dNaN** Default quiet NaN
- **E(0)** The value of zero with the exponent value Te is placed in FRT[p].
- **L(x)** The operand x is converted to the form with the exponent value Te.
- **p** The precision of the format.
- **QR(x)** The operand x is rounded to the result of the form with the exponent value Te based on the specified rounding mode. The result of that form is placed in FRT[p].
- **Se** The exponent of the operand in FRB[p].
- **Te** The target exponent; FRA[p] for dqua[q], or TE, a 5-bit signed binary integer for dqua[q].
- **T(x)** The value x is placed in FRT[p].
- **Vb** The value of the operand in FRB[p].
- **W(x)** The value and the form of operand x is placed in FRT[p].
- **VXCVI**: Floating-Point Invalid Operation (Invalid Conversion) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 199.)

</tbody>
</table>

Let $k$ be the contents of bits 58:63 of FRA that specifies the reference significance.

When the DFP operand in FRB[p] is a finite number, and if the reference significance is zero, or if the reference significance is nonzero and the number of significant digits of the source operand is less than or equal to the reference significance, then the value and the form of the source operand is placed in FRT[p]. If the reference significance is nonzero and the number of significant digits of the source operand is greater than the reference significance, then the source operand is converted and rounded to the number of significant digits specified in the reference significance based on the rounding mode specified in the RMC field. The result of the form with the specified number of significant digits is placed in FRT[p]. The sign of the result is the same as the sign of the operand in FRB[p].

For this instruction, the number of significant digits of the value 0 is considered to be zero. The ideal exponent is the greater value of the exponent of the operand in FRB[p] and the referenced exponent. The referenced exponent is the resultant exponent if the operand in FRB[p] would have been converted and rounded to the number of significant digits specified in the reference significance based on the rounding mode specified by RMC.

If the exponent of the rounded result of the form that has the specified number of significant digits would be greater than $X_{max}$, an invalid operation exception (VXCVI) occurs. When the invalid-operation exception occurs, and if the exception is disabled, a default QNaN is returned. When an invalid-operation exception occurs, no inexact exception is recognized.

In the absence of an invalid-operation exception, if the result differs in value from the operand in FRB[p], an inexact exception is recognized.

This operation causes neither an overflow nor an underflow exception.

Figure 90 summarizes the actions for Reround. The table does not include the setting of FPRF. FPRF is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

drrnd[q][.] are treated as Floating-Point instructions in terms of resource availability.

**Special Registers Altered:**

- FPRF FR FI
- FX XX
- VXSNAN VXCVI
- CR1 (if $Rc=1$)

**Programming Note**

**DFP Reround** can be used to adjust a DFP value (FRB[p]) to have no more than a specified number (FRA[p]58:63) of significant digits. The result (FRT[p]) is right-justified leaving the specified number of digits and rounded as specified by RMC. If rounding increases the number of significant digits, the result is adjusted again (the significand is shifted right 1 digit and the exponent is incremented by 1). Figure 89 has example results from **DFP Reround** for 1, 2, and 10 significant digits.
Programming Note

DFP Reround is primarily used to round a DFP value to a specific number of digits before conversion to string format for printing or display. Another use for DFP Reround is to obtain the effective exponent of the most significant digit by specifying a reference significance of 1. The exponent can be extracted and used to compute the number of significant digits or to left-justify a value.

For example, the following sequence computes the number of significant digits and returns it as an integer. FRB is the DFP value for which we want the number of significant digits; f13 contains the reference significance value 0x0000000000000001; and r1 is the stack pointer, with free space for doublewords at offsets -8 and -16. These doublewords are used to transfer the biased exponents from the FPRs to GPRs for integer computation. R3 contains the result of $E(reround(1, \text{FRA}) - E(\text{FRA}) + 1$, where $E(x)$ represents the biased exponent of $x$.

```assembly
dxex f0,FRB
stfd f0,-16(r1)
drrnd f1,f13,FRB,1 # reround 1 digit toward 0
dxex f1,f1
stfd f1,-8(r1)
lfd r11,-16(r1)
lfd r3,-8(r1)
subf r3,r11,r3
addi r3,r3,1
```

Given the value 412.34 the result is $E(4 \times 10^2) - E(41234 \times 10^{-2}) + 1 = (398+2) - (398-2) + 1 = 400 - 396 + 1 = 5$. Additional code is required to detect and handle special values like Subnormal, Infinity, and NAN.

</tr>
</tbody>
</table>

Figure 89. DFP Reround examples
### Programming Note

DFP **Reround** combined with **DFP Quantize** can be used to left justify a value (as needed by the frexp function). **DFP Reround** is the DFP value for which we want to left justify; \( f_{13} \) contains the reference significance value \( 0x0000000000000001 \); and \( r1 \) is the stack pointer, with free space for a doubleword at offset -8. This doubleword is used to transfer the biased exponents from the FPR to a GPR, for integer computation. The adjusted biased exponent (+ format precision - 1) is transferred back into an FPR so it can be inserted into the rerounded value. The adjusted rerounded value becomes the quantize reference value. The quantize instruction returns the left justified result in FRT.

\[
\text{drrnd } f1, f_{13}, FRB, 1 \# \text{reround 1 digit toward 0} \\

</tr>
</tbody>
</table>

**Explanation:**

* The number of significant digits of the value 0 is considered to be zero for this instruction.
- Not applicable.

- **dINF**: Default infinity.
- **fn**: Finite nonzero numbers (includes both subnormal and normal numbers).
- **k**: Reference significance, which specifies the number of significant digits in the target operand.
- **m**: Number of significant digits in the operand in FRB\[p\].
- **P(x)**: The QNaN of operand x is propagated and placed in FRT\[p\].
- **RR(x)**: The value x is rounded to the form that has the specified number of significant digits.
  - If \( \text{RR}(x) \leq (10^{k-1} \times 10^{\text{max}}) \), then \( \text{RR}(x) \) is returned; otherwise an invalid-operation exception is recognized.
- **T(x)**: The value x is placed in FRT\[p\].
- **U(x)**: The SNaN of operand x is converted to the corresponding QNaN and placed in FRT\[p\].
- **VXCVI**: Floating-Point Invalid Operation (Invalid Conversion) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 199.)
- **VXSNAN**: Floating-Point Invalid Operation (SNaN) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 199.)
- **W(x)**: The value and the form of x is placed in FRT\[p\].

**Figure 90. Actions: Reround**
**DFP Round To FP Integer With Inexact Z23-form**

\[
\text{drntx} \quad R,FRT,FRB,RMC \quad (Rc=0) \\
\text{drntx.} \quad R,FRT,FRB,RMC \quad (Rc=1)
\]

The DFP operand in \( FRB[p] \) is rounded to a floating-point integer and placed into \( FRT[p] \). The sign of the result is the same as the sign of the operand in \( FRB[p] \). The ideal exponent is the larger value of zero and the exponent of the operand in \( FRB[p] \).

The rounding mode used is specified by \( RMC \). When the \( RMC\)-encoding-selection (R) bit is zero, \( RMC \) field contains the primary encoding; when the bit is one, the field contains the secondary encoding.

In addition to coercion of the converted value to fit the target format, the special rounding used by *Round To FP Integer* also coerces the target exponent to the ideal exponent.

When the operand in \( FRB[p] \) is a finite number and the exponent is less than zero, the operand is rounded to the result with an exponent of zero. When the exponent is greater than or equal to zero, the result is set to the numerical value and the form of the operand in \( FRB[p] \).

When the result differs in value from the operand in \( FRB[p] \), an inexact exception is recognized. No underflow exception is recognized by this operation, regardless of the value of the operand in \( FRB[p] \).

Figure 91 summarizes the actions for *Round To FP Integer With Inexact*. The table does not include the setting of \( FPRF \). \( FPRF \) is always set to the class and sign of the result, except for an enabled invalid-operation, in which case the field remains unchanged.

\[ \text{drntx[q][.:]} \text{ are treated as Floating-Point instructions in terms of resource availability.} \]

**Programming Note**

The **DFP Round To FP Integer With Inexact** and **DFP Round To FP Integer With Inexact Quad** instructions can be used to implement the decimal equivalent of the C99 rint function by specifying the primary \( RMC \) encoding for round according to DRN \((R=0, RMC=11)\). The specification for rint requires the inexact exception be raised if detected.

**Special Registers Altered:**

\[
\begin{array}{ccccccc}
\text{FPRF} & \text{FR} & \text{FI} & \text{FX} & \text{XX} & \text{VXSNAN} & \text{CR1}
\end{array}
\]

\( (\text{if } Rc=1) \)
### Table: Actions: Round to FP Integer With Inexact

| Operand b in FRB is | Is n not precise (n \(\neq b\)) | Inv.-Op. Exception Enabled | Inexact Exception Enabled | Is n Incremented (|n| > |b|) | Actions* |
|---------------------|----------------------------------|---------------------------|---------------------------|---------------------------------|----------|

| F                  | No                               |                           |                           |                                 | \(W(n), \text{FI} \leftarrow 1, \text{FR} \leftarrow 0, \text{XX} \leftarrow 1\) |
| F                  | Yes                              |                           | No                        | No                              | \(W(n), \text{FI} \leftarrow 1, \text{FR} \leftarrow 1, \text{XX} \leftarrow 1\) |
| F                  | Yes                              |                           | No                        | No                              | \(W(n), \text{FI} \leftarrow 1, \text{FR} \leftarrow 1, \text{XX} \leftarrow 1\) |
| F                  | Yes                              |                           | Yes                       | No                              | \(W(n), \text{FI} \leftarrow 1, \text{FR} \leftarrow 1, \text{XX} \leftarrow 1, \text{TX}\) |
| \(+\infty\)        | No\(^1\)                         |                           |                           |                                 | \(T(+d\text{INF}), \text{FI} \leftarrow 0, \text{FR} \leftarrow 0\) |
| QNaN               | No\(^1\)                         |                           |                           |                                 | \(P(b), \text{FI} \leftarrow 0, \text{FR} \leftarrow 0\) |
| SNaN               | No\(^1\)                         |                           |                           |                                 | \(U(b), \text{FI} \leftarrow 0, \text{FR} \leftarrow 0, \text{VXSNAN} \leftarrow 1\) |
| SNaN               | No\(^1\)                         |                           |                           |                                 | \(VXSNAN \leftarrow 1, \text{TX}\) |

* Setting of XX and VXSNAN is part of the corresponding exception actions. Also, when an invalid-operation exception occurs, setting of \(\text{FI}\) and \(\text{FR}\) is part of the exception actions. (See the sections, "Inexact Exception" and "Invalid Operation Exception" for more details.)

- The actions do not depend on this condition.
- This condition is true by virtue of the state of some condition to the left of this column.

\(d\text{INF}\): Default infinity.
\(F\): All finite numbers, including zeros.
\(FI\): Floating-Point Fraction Inexact status bit.
\(FR\): Floating-Point Fraction Rounded status bit.
\(n\): The value derived when the source operand, b, is rounded to an integer using the special rounding for Round To FP Integer.
\(P(x)\): The QNaN of operand x is propagated and placed in \(FRT[p]\).
\(T(x)\): The value x is placed in \(FRT[p]\).
\(TV\): The system floating-point enabled exception error handler is invoked for the invalid operation exception if \(\text{FE}0\) and \(\text{FE}1\) are set to any mode other than the ignore-exception mode.
\(TX\): The system floating-point enabled exception error handler is invoked for the inexact exception if \(\text{FE}0\) and \(\text{FE}1\) are set to any mode other than the ignore-exception mode.
\(U(x)\): The SNaN of operand x is converted to the corresponding QNaN and placed in \(FRT[p]\).
\(W(x)\): The value x in the form of zero exponent or the source exponent is placed in \(FRT[p]\).

**Explanation:**

<td>11</td>
<td>16</td>
<td>21</td>
<td>23</td>
<td>31</td>
<td></td>
</tr>
</tbody>
</table>

This operation is the same as the Round To FP Integer With Inexact operation, except that this operation does not recognize an inexact exception.

Figure 92 summarizes the actions for Round To FP Integer Without Inexact. The table does not include the setting of FPRF. FPRF is always set to the class and sign of the result, except for an enabled invalid-operation, in which case the field remains unchanged.

drintn[q][.] are treated as Floating-Point instructions in terms of resource availability.

Special Registers Altered:
FPRF FR (set to 0) F1 (set to 0)
FX
VXSNAN
CR1 (if Rc=1)

Programming Note

The DFP Round To FP Integer Without Inexact and DFP Round To FP Integer Without Inexact Quad instructions can be used to implement decimal equivalents of several C99 rounding functions by specifying the appropriate R and RMC field values.

<table>
<thead>
<tr>
<th>Function</th>
<th>R</th>
<th>RMC</th>

Explanation:
- Setting of \(VXSNAN\) is part of the corresponding exception actions. Also, when an invalid-operation exception occurs, setting of \(F_{1}\) and \(FR\) bits is part of the exception actions. (See the sections, "Invalid Operation Exception" for more details.)
- The actions do not depend on this condition.

\(d_{\text{Inf}}\) Default infinity.
\(F\) All finite numbers, including zeros.
\(F_{1}\) Floating-Point Fraction Inexact status bit.
\(FR\) Floating-Point Fraction Rounded status bit.
\(n\) The value derived when the source operand, \(b\), is rounded to an integer using the special rounding for Round To FP Integer.
\(P(x)\) The QNaN of operand \(x\) is propagated and placed in \(FRT[p]\).
\(T(x)\) The value \(x\) is placed in \(FRT[p]\).
\(TV\) The system floating-point enabled exception error handler is invoked for the invalid-operation exception if \(FE0\) and \(FE1\) are set to any mode other than the ignore-exception mode.
\(U(x)\) The SNaN of operand \(x\) is converted to the corresponding QNaN and placed in \(FRT[p]\).
\(W(x)\) The value \(x\) in the form of zero exponent or the source exponent is placed in \(FRT[p]\).

Figure 92. Actions: Round to FP Integer Without Inexact
5.6.5 DFP Conversion Instructions

The DFP conversion instructions consist of data-format conversion instructions and data-type conversion instructions. They are all X-form instructions and employ the record bit (Rc).

5.6.5.1 DFP Data-Format Conversion Instructions

The data-format conversion instructions consist of Convert To DFP Long, Convert To DFP Extended, Round To DFP Short, and Round To DFP Long. Figure 93 summarizes the actions for these instructions.

### Programming Note

DFP does not provide operations on short operands, so they must be converted to long format, and then converted back to be stored. Preserving correct signaling NaN semantics requires that signaling NaNs be propagated from the source to the result without recognizing an exception during widening from short to long or narrowing from long to short. Because DFP does not provide equivalents to the FP Load Floating-Point Single and Store Floating-Point Single functions, the widening is performed by loading the DFP short value with a Load Floating as Integer Word Indexed followed by a DFP Convert to DFP Long, and narrowing is performed by a DFP Round to DFP Short followed by a Store Floating-Point as Integer Word Indexed. If the SNaN or infinity in DFP short format uses the preferred DPD encoding, then converting this operand to DFP long format and back to DFP short will result in the original bit pattern.

---

<table>
<thead>
<tr>

<tr>
<td>Round To DFP Short</td>
<td>R(b) 1</td>
</tr>
<tr>
<td>Round To DFP Long</td>
<td>R(b) 1</td>
</tr>
</tbody>
</table>

**Explanation:**

1. The ideal exponent is the exponent of the source operand.
2. Bits 5:N-1 of the N-bit combination field are set to zero.
3. Bit 5 of the N-bit combination field is set to one. Bits 6:N-1 of the combination field are set to zero.
4. The trailing significand field is padded on the left with zeros.
5. Leftmost digits in the trailing significand field are removed.
6. Default infinity.
7. All finite numbers, including zeros.
8. The special symbol in operand x is propagated into FRT[p].
9. The value x is rounded to the target-format precision; see Section 5.5.11
10. The value x is placed in FRT[p].
11. The SNaN of operand x is converted to the corresponding QNaN.
12. Floating-Point Invalid Operation (SNaN) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 199.)

Figure 93. Actions: Data-Format Conversion Instructions
**DFP Convert To DFP Long X-form**

\[
\begin{array}{cccccc}
\text{Rc} & \text{0} & \text{6} & \text{11} & \text{16} & \text{21} & \text{31} \\
\text{FRT} & \text{FRB} & \text{258} & \\
\text{0} & \text{32:63} & \\
\end{array}
\]

The DFP short operand in bits 32:63 of FRB is converted to DFP long format and the converted result is placed into FRT. The sign of the result is the same as the sign of the source operand. The ideal exponent is the exponent of the source operand.

If the operand in FRB is an SNaN, it is converted to an SNaN in DFP long format and does not cause an invalid-operation exception.

\[
\text{dctdp} \quad \text{FRT,FRB} \quad (\text{Rc}=0) \\
\text{dctdp} \quad \text{FRT,FRB} \quad (\text{Rc}=1)
\]

**DFP Convert To DFP Extended X-form**

\[
\begin{array}{cccccc}
\text{Rc} & \text{0} & \text{6} & \text{11} & \text{16} & \text{21} & \text{31} \\
\text{FRT} & \text{FRB} & \text{258} & \\
\text{0} & \text{63} & \text{11} & \text{16} & \text{21} & \text{31} \\
\end{array}
\]

The DFP long operand in the FRB is converted to DFP extended format and placed into FRTp. The sign of the result is the same as the sign of the operand in FRB. The ideal exponent is the exponent of the operand in FRB.

If the operand in FRB is an SNaN, an invalid-operation exception is recognized. If the exception is disabled, the SNaN is converted to the corresponding QNaN in DFP extended format.

\[
\text{dctpq} \quad \text{FRTp,FRB} \quad (\text{Rc}=0) \\
\text{dctpq} \quad \text{FRTp,FRB} \quad (\text{Rc}=1)
\]

**Programming Note**

Note that DFP short format is a storage-only format, Therefore, conversion of a short SNaN to long format will not cause an exception and the SNaN is preserved. Subsequent operation on that SNaN in long format will cause an exception.
**DFP Round To DFP Short X-form**

drsp  FRT,FRB  \((Rc=0)\)
drsp. FRT,FRB  \((Rc=1)\)

The DFP long operand in \(FRB\) is converted and rounded to DFP short format. The DFP short value is extended on the left with zeros to form a 64-bit entity and placed into \(FRT\). The sign of the result is the same as the sign of the source operand. The ideal exponent is the exponent of the source operand.

If the operand in \(FRB\) is an SNaN, it is converted to an SNaN in DFP short format and does not cause an invalid-operation exception.

Normally, the result is in the format and length of the target. However, when an overflow or underflow exception occurs and if the exception is enabled, the operation is completed by producing a wrapped rounded result in the same format and length as the source but rounded to the target-format precision.

**Programming Note**

Note that DFP short format is a storage-only format, therefore, conversion of a long SNaN to short format will not cause an exception. Converting a long format SNaN to short format is an implied move operation.

**Special Registers Altered:**

\[
\begin{array}{cccccc}
FPRF & FR & FI & FX & OX & UX & XX \\
CR1 & & & & & & (if \(Rc=1\))
\end{array}
\]

**drsp[.]** are treated as Floating-Point instructions in terms of resource availability.

**DFP Round To DFP Long X-form**

drdpq  FRTp,FRBp  \((Rc=0)\)
drdpq. FRTp,FRBp  \((Rc=1)\)

The DFP extended operand in \(FRBp\) is converted and rounded to DFP long format. The result concatenated with 64 0s is placed in \(FRTp\). The sign of the result is the same as the sign of the source operand. The ideal exponent is the exponent of the operand in \(FRBp\).

If the operand in \(FRBp\) is an SNaN, an invalid-operation exception is recognized. If the exception is disabled, the SNaN is converted to the corresponding QNaN in DFP long format.

Normally, the result is in the format and length of the target. However, when an overflow or underflow exception occurs and if the exception is enabled, the operation is completed by producing a wrapped rounded result in the same format and length as the source but rounded to the target-format precision.

**Programming Note**

Note that DFP Round to DFP Long, while producing a result in DFP long format, actually targets a register pair, writing 64 0s in \(FRTp+1\).

**Special Registers Altered:**

\[
\begin{array}{cccccc}
FPRF & FR & FI & FX & OX & UX & XX \\
VXSNAN & & & & & & (if \(Rc=1\))
\end{array}
\]

**drdpq[.]** are treated as Floating-Point instructions in terms of resource availability.
5.6.5.2 DFP Data-Type Conversion Instructions

The DFP data-type conversion instructions are used to convert data type between DFP and fixed.

The data-type conversion instructions consist of Convert From Fixed and Convert To Fixed.

### DFP Convert From Fixed X-form

<table>
<thead>
<tr>
<th>dcffix</th>
<th>FRT,FRB (Rc=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>dcffix</td>
<td>FRT,FRB (Rc=1)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>59</th>
<th>FRT</th>
<th>//</th>
<th>FRB</th>
<th>802</th>
<th>R</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>31</td>
</tr>
</tbody>
</table>

The 64-bit signed binary integer in FRB is converted and rounded to a DFP Long value and placed into FRT. The sign of the result is the same as the sign of the source operand. The ideal exponent is zero.

If the source operand is a zero, then a plus zero with a zero exponent is returned.

FPRF is set to the class and sign of the result.

**dcffix[]** are treated as Floating-Point instructions in terms of resource availability.

**Special Registers Altered:**

- FPRF FR FI
- FX XX
- CR1 (if Rc=1)

### DFP Convert From Fixed Quad X-form

<table>
<thead>
<tr>
<th>dcffixq</th>
<th>FRTp,FRB (Rc=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>dcffixq</td>
<td>FRTp,FRB (Rc=1)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>63</th>
<th>FRTp</th>
<th>//</th>
<th>FRB</th>
<th>802</th>
<th>R</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>31</td>
</tr>
</tbody>
</table>

The 64-bit signed binary integer in FRB is converted and rounded to a DFP Extended value and placed into FRTp. The sign of the result is the same as the sign of the source operand. The ideal exponent is zero.

If the source operand is a zero, then a plus zero with a zero exponent is returned.

FPRF is set to the class and sign of the result.

**dcffixq[]** are treated as Floating-Point instructions in terms of resource availability.

**Special Registers Altered:**

- FPRF FR (undefined) FI (undefined)
- CR1 (if Rc=1)
**DFP Convert From Fixed Quadword Quad X-form**

\[ \text{dcffixqq} \rightarrow \text{FRTp, VRB} \]

<table>
<thead>
<tr>
<th>63</th>
<th>FRTp</th>
<th>VRB</th>
<th>994</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
</tr>
</tbody>
</table>

The 128-bit signed binary integer in VRB is converted and rounded to a DFP Extended value and placed into FRTp. The sign of the result is the same as the sign of the source operand. The ideal exponent is zero.

If the source operand is a zero, then a plus zero with a zero exponent is returned.

FPRF is set to the class and sign of the result.

\( \text{dcffixqq} \) is treated as a Floating-Point and a Vector instruction in terms of resource availability.

**Special Registers Altered:**

FPRF FR FI FX XX

**VSR Data Layout for dcffixqq**

<table>
<thead>
<tr>
<th>src</th>
<th>VSR[VRB+32]</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>result</th>
<th>VSR[FRTp].dword[0]</th>
<th>0x0000_0000_0000_0000</th>
</tr>

<th>FRT,FRB</th>
<th>(Rc=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>dctfix.</td>
<td>FRT,FRB</td>
<td>(Rc=1)</td>
</tr>
</tbody>
</table>

The DFP operand in FRB[p] is rounded to an integer value and is placed into FRT in the 64-bit signed binary integer format. The sign of the result is the same as the sign of the source operand, except when the source operand is a NaN or a zero.

Figure 94 summarizes the actions for Convert To Fixed.

**dfctfix[q][]** are treated as Floating-Point instructions in terms of resource availability.

**Special Registers Altered:**
- FPRF (undefined)
- FR FI
- FX XX
- VXSNAN VXCVI
- CR1

**Programming Note**

It is recommended that software pre-round the operand to a floating-point integral using **drintx[q]** or **drintn[q]** if a rounding mode other than the current rounding mode specified by DRN is needed. Saving, modifying and restoring the FPSCR just to temporarily change the rounding mode is less efficient than just employing drintx[p] or drint[p] which override the current rounding mode using an immediate control field.

For example if the desired function rounding is Round to Nearest, Ties away from 0 but the default rounding (from DRN) is Round to Nearest, Ties to Even then following is preferred.

```
drintn  0,f1,f1,2
dctfix  f1,f1
```

**VSR Data Layout for dctfixqq**

<table>

Explanation:

* Setting of XX, VXCVI, and VXSNAN is part of the corresponding exception actions. Also, when an invalid-operation exception occurs, setting of FI and FR bits is part of the exception actions. (See the sections, “Inexact Exception” and “Invalid Operation Exception” for more details.)

- The actions do not depend on this condition.

FI Floating-Point Fraction Inexact status bit.
FR Floating-Point Fraction Rounded status bit.
MN Maximum negative number representable by the 64-bit binary integer format
MP Maximum positive number representable by the 64-bit binary integer format
n The value q converted to a fixed-point result.
q The value derived when the source value b is rounded to an integer using the specified rounding mode
T(x) The value x is placed in FRT[p].
TV The system floating-point enabled exception error handler is invoked for the invalid-operation exception if FE0 and FE1 are set to any mode other than the ignore-exception mode.
TX The system floating-point enabled exception error handler is invoked for the inexact exception if FE0 and FE1 are set to any mode other than the ignore-exception mode.
VXCVI Floating-Point Invalid Operation (Invalid Conversion) exception status bit.
VXSNAN Floating-Point Invalid Operation (SNaN) exception status bit.
XX Floating-Point Inexact exception status bit.

Figure 94. Actions: Convert To Fixed
5.6.6 DFP Format Instructions

The DFP format instructions are used to compose or decompose a DFP operand. A source operand of SNaN does not cause an invalid-operation exception. All format instructions employ the record bit (Rc).

DFP Decode DPD To BCD X-form

<table>
<thead>
<tr>
<th>ddedpd</th>
<th>SP, FRT, FRB</th>
<th>(Rc=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ddedpd.</td>
<td>SP, FRT, FRB</td>
<td>(Rc=1)</td>
</tr>
</tbody>
</table>

DFP Decode DPD To BCD Quad X-form

<table>
<thead>
<tr>
<th>ddedpdq</th>
<th>SP, FRTp, FRBp</th>
<th>(Rc=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ddedpdq.</td>
<td>SP, FRTp, FRBp</td>
<td>(Rc=1)</td>
</tr>
</tbody>
</table>

A portion of the significand of the DFP operand in FRB[p] is converted to a signed or unsigned BCD number depending on the SP field. For infinity and NaN, the significand is considered to be the contents in the trailing significand field padded on the left by a zero digit.

SP0 = 0 (unsigned conversion)

The rightmost 16 digits of the significand (32 digits for ddedpdq) is converted to an unsigned BCD number and the result is placed into FRT[p].

SP0 = 1 (signed conversion)

The rightmost 15 digits of the significand (31 digits for ddedpdq) is converted to a signed BCD number with the same sign as the DFP operand, and the result is placed into FRT[p]. If the DFP operand is negative, the sign is encoded as 0b1101. If the DFP operand is positive, SP1 indicates which preferred plus sign encoding is used. If SP1 = 0, the plus sign is encoded as 0b1100 (the option-1 preferred sign code), otherwise the plus sign is encoded as 0b1111 (the option-2 preferred sign code).

ddedpdq[p][] are treated as Floating-Point instructions in terms of resource availability.

Special Registers Altered:

CR1 \((\text{if } Rc=1)\)

DFP Encode BCD To DPD X-form

<table>
<thead>
<tr>
<th>denbcd</th>
<th>S, FRT, FRB</th>
<th>(Rc=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>denbcd.</td>
<td>S, FRT, FRB</td>
<td>(Rc=1)</td>
</tr>
</tbody>
</table>

DFP Encode BCD To DPD Quad X-form

<table>
<thead>
<tr>
<th>denbcdq</th>
<th>S, FRTp, FRBp</th>
<th>(Rc=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>denbcdq.</td>
<td>S, FRTp, FRBp</td>
<td>(Rc=1)</td>
</tr>
</tbody>
</table>

The signed or unsigned BCD operand, depending on the S field, in FRB[p] is converted to a DFP number. The ideal exponent is zero.

S = 0 (unsigned BCD operand)

The unsigned BCD operand in FRB[p] is converted to a positive DFP number of the same magnitude and the result is placed into FRT[p].

S = 1 (signed BCD operand)

The signed BCD operand in FRB[p] is converted to the corresponding DFP number and the result is placed into FRT[p].

If an invalid BCD digit or sign code is detected in the source operand, an invalid-operation exception (VXCVI) occurs.

FPRF is set to the class and sign of the result, except for Invalid Operation Exception when VE=1.

denbcdq[p][] are treated as Floating-Point instructions in terms of resource availability.

Special Registers Altered:

FPRF FR (set to 0) FI (set to 0)
FX
VXCVI
CR1 \((\text{if } Rc=1)\)
**DFP Extract Biased Exponent X-form**

\[
dxex \rightarrow \text{FRT,FRB} \quad (Rc=0) \\
dxex. \rightarrow \text{FRT,FRB} \quad (Rc=1)
\]

**DFP Extract Biased Exponent Quad X-form**

\[
dxexq \rightarrow \text{FRT,FRBp} \quad (Rc=0) \\
dxexq. \rightarrow \text{FRT,FRBp} \quad (Rc=1)
\]

The biased exponent of the operand in \(\text{FRB}[p]\) is extracted and placed into \(\text{FRT}\) in the 64-bit signed binary integer format. When the operand in \(\text{FRB}\) is an infinity, QNaN, or SNaN, a special code is returned.

\(dxex[q][]\) are treated as Floating-Point instructions in terms of resource availability.

**Special Registers Altered:**

- CR1 
  (if \(Rc=1\))

---

**Programming Note**

The exponent bias value is 101 for DFP Short, 398 for DFP Long, and 6176 for DFP Extended.

---

**DFP Insert Biased Exponent X-form**

\[
diex \rightarrow \text{FRT,FRA,FRB} \quad (Rc=0) \\
diex. \rightarrow \text{FRT,FRA,FRB} \quad (Rc=1)
\]

**DFP Insert Biased Exponent Quad X-form**

\[
diexq \rightarrow \text{FRTp,FRA,FRBp} \\
diexq. \rightarrow \text{FRTp,FRA,FRBp} \quad (Rc=1)
\]

Let \(a\) be the value of the 64-bit signed binary integer in \(\text{FRA}\).

\[
\begin{align*}
\text{Operand} & \quad \text{Result} \\
\text{Finite Number} & \quad \text{biased exponent value} \\
\text{Infinity} & \quad -1 \\
\text{QNaN} & \quad -2 \\
\text{SNaN} & \quad -3 \\
\end{align*}
\]

When \(0 \leq a \leq \text{MBE}\), \(a\) is the biased target exponent that is combined with the sign bit and the significand value of the DFP operand in \(\text{FRB}[p]\) to form the DFP result in \(\text{FRT}[p]\). The ideal exponent is the specified target exponent.

When \(a\) specifies a special code (\(a < 0\) or \(a > \text{MBE}\)), an infinity, QNaN, or SNaN is formed in \(\text{FRT}[p]\) with the trailing significand field containing the value from the trailing significand field of the source operand in \(\text{FRB}[p]\), and with an N-bit combination field set as follows.

- For an Infinity result,
  - the leftmost 5 bits are set to \(0b11110\), and
  - the rightmost N-5 bits are set to zero.
- For a QNaN result,
  - the leftmost 5 bits are set to \(0b11111\),
  - bit 5 is set to zero, and
  - the rightmost N-5 bits are set to zero.
- For an SNaN result,
  - the leftmost 5 bits are set to \(0b11111\),
  - bit 5 is set to one, and
  - the rightmost N-5 bits are set to zero.

\(dxex[q][]\) are treated as Floating-Point instructions in terms of resource availability.

**Special Registers Altered:**

- CR1 
  (if \(Rc=1\))

---

**Programming Note**

The exponent bias value is 101 for DFP Short, 398 for DFP Long, and 6176 for DFP Extended.
Operand a in \( FRA[p] \) specifies

<table>
<thead>
<tr>
<th>Actions for Insert Biased Exponent when operand b in FRB[p] specifies</th>
<th>F</th>
<th>( \infty )</th>
<th>QNaN</th>
<th>SNaN</th>

The significand of the DFP operand in FRA[p] is shifted left \( SH \) digits. For a NaN or infinity, all significand digits are in the trailing significand field. \( SH \) is a 6-bit unsigned binary integer. Digits shifted out of the leftmost digit are lost. Zeros are supplied to the vacated positions on the right. The result is placed into FRT[p]. The sign of the result is the same as the sign of the source operand in FRA[p].

If the source operand in FRA[p] is a finite number, the exponent of the result is the same as the exponent of the source operand.

For an Infinity, QNaN or SNaN result, the target format’s N-bit combination field is set as follows.

- For an Infinity result,
  - the leftmost 5 bits are set to 0b11110, and
  - the rightmost N-5 bits are set to zero.

- For a QNaN result,
  - the leftmost 5 bits are set to 0b11111,
  - bit 5 is set to zero, and
  - the rightmost N-6 bits are set to zero.

- For an SNaN result,
  - the leftmost 5 bits are set to 0b11111,
  - bit 5 is set to one, and
  - the rightmost N-6 bits are set to zero.

**dscl[q][.]** are treated as *Floating-Point* instructions in terms of resource availability.

Explanation:

# FI and FR are set to zeros for these instructions.
- Not applicable.
1 A unique definition of the FPSCR\_PPC field is provided for the instruction.
2 These are the only instructions that may generate an SNaN and also set the FPSCR\_FPRF field. Since the BFP FPRF field does not include a code for SNaN, these instructions cause the need for redefining the FPRF field for DFP.

DCM A 6-bit immediate operand specifying the data-class mask.
DGM A 6-bit immediate operand specifying the data-group mask.
G An SNaN can be generated as the target operand.
IE An ideal exponent is defined for the instruction.
FI Setting of the FPSCR\_FI flag.
FR Setting of the FPSCR\_FR flag.
N No.
O An overflow exception may be recognized.
Rc The record bit, Rc, is provided to record FPSCR\_32:35 in CR field 1.
RE The trailing significand field is reencoded using preferred DPD encodings. The preferred DPD encoding are also used for propagated NaNs, or converted NaNs and infinities.
RMC A 2-bit immediate operand specifying the rounding-mode control.
S An one-bit immediate operand specifying if the operation is signed or unsigned.
Explanation:

- **SP**: A two-bit immediate operand: one bit specifies if the operation is signed or unsigned and, for signed operations, another bit specifies which preferred plus sign code is generated.
- **U**: An underflow exception may be recognized.
- **V**: An invalid-operation exception may be recognized.
- **Vs**: An input operand of SNaN causes an invalid-operation exception.
- **X**: An inexact exception may be recognized.
- **Y**: Yes.
- **U**: Undefined
- **Z**: A zero-divide exception may be recognized.
Chapter 6. Vector Facility

6.1 Vector Facility Overview
This chapter describes the registers and instructions that make up the Vector Facility.

6.2 Chapter Conventions

6.2.1 Description of Instruction Operation
The following notation, in addition to that described in Section 1.3.2, is used in this chapter.

- \texttt{x.bit[y]} \quad Return the contents of bit y of x.
- \texttt{x.bit[y:z]} \quad Return the contents of bits y:z of x.
- \texttt{x.nibble[y]} \quad Return the contents of the 4-bit nibble element y of x.
- \texttt{x.nibble[y:z]} \quad Return the contents of the 4-bit nibble elements y:z of x.
- \texttt{x.byte[y]} \quad Return the contents of 8-bit byte element y of x.
- \texttt{x.byte[y:z]} \quad Return the contents of 8-bit byte elements y:z of x.
- \texttt{x.hword[y]} \quad Return the contents of 16-bit halfword element y of x.
- \texttt{x.hword[y:z]} \quad Return the contents of 16-bit halfword elements y:z of x.
- \texttt{x.word[y]} \quad Return the contents of 32-bit word element y of x.
- \texttt{x.word[y:z]} \quad Return the contents of 32-bit word element y:z of x.
- \texttt{x.dword[y]} \quad Return the contents of 64-bit doubleword element y of x.
- \texttt{x.dword[y:z]} \quad Return the contents of 64-bit doubleword elements y:z of x.
- \texttt{x.qword[y]} \quad Return the contents of 128-bit quadword element y of x.
- \texttt{x ? y : z} \quad if the value of x is true, then the value of y, otherwise the value z.
- \texttt{+} \quad Addition.
- \texttt{-} \quad Subtraction.
- \texttt{\times} \quad Multiplication.
- \texttt{~} \quad One’s complement.
- \texttt{=, <, <=, >, >=} \quad Equal, less than, less than or equal, greater than, and greater than or equal comparison relations.
\( x \ll y \)
Result of shifting \( x \) left by \( y \) bits, filling vacated bits with zeros.

\[
b \leftarrow \text{LENGTH}(x) \\
\text{result} \leftarrow x \\
do ~ i = 0 \text{ to } y-1 \\
\quad \text{result} \leftarrow \text{result}.\text{bit}[1:b-1] \ || \ 0b0
\]

\( x \gg y \)
Result of shifting \( x \) right by \( y \) bits, filling vacated bits with copies of bit 0 of \( x \).

\[
b \leftarrow \text{LENGTH}(x) \\
\text{result} \leftarrow x \\
do ~ i = 0 \text{ to } y-1 \\
\quad \text{result} \leftarrow \text{result}.\text{bit}[0] \ || \ \text{result}.\text{bit}[0:b-2]
\]

\( x \lll y \)
Result of rotating \( x \) left by \( y \) bits.

\[
b \leftarrow \text{LENGTH}(x) \\
\text{result} \leftarrow x.\text{bit}[y:b-1] \ || \ x.\text{bit}[0:y-1]
\]

\( x \ggg y \)
Result of rotating \( x \) right by \( y \) bits.

\[
b \leftarrow \text{LENGTH}(x) \\
\text{result} \leftarrow x.\text{bit}[b-y+1:b-1] \ || \ x.\text{bit}[0:b-y]
\]

\text{bcd}_\text{ADD}(x,y,z)
Let \( x \) and \( y \) be 31-digit signed decimal values.
Performs a signed decimal addition of \( x \) and \( y \).

If the unbounded result is equal to zero, \eq_{\text{flag}} \) is set to 1. Otherwise, \eq_{\text{flag}} \) is set to 0.
If the unbounded result is greater than zero, \gt_{\text{flag}} \) is set to 1. Otherwise, \gt_{\text{flag}} \) is set to 0.
If the unbounded result is less than zero, \lt_{\text{flag}} \) is set to 1. Otherwise, \lt_{\text{flag}} \) is set to 0.

If the magnitude of the unbounded result is greater than \( 10^{31-1} \), \ox_{\text{flag}} \) is set to 1. Otherwise, \ox_{\text{flag}} \) is set to 0.

If the unbounded result is greater than or equal to zero, the sign code of the result is set to \( 0b1100 \) if \( z=0 \).
If the unbounded result is greater than or equal to zero, the sign code of the result is set to \( 0b1111 \) if \( z=1 \).
If the unbounded result is less than zero, the sign code of the result is set to \( 0b1101 \).

The low-order 31 digits of the unbounded result magnitude concatenated with the sign code are returned.

If either operand is an invalid encoding of a signed decimal value, the result returned is undefined and \inv_{\text{flag}} \) is set to 1 and \lt_{\text{flag}}, \gt_{\text{flag}} \) and \eq_{\text{flag}} \) are set to 0. Otherwise, \inv_{\text{flag}} \) is set to 0.
bcd_CONVERT_FROM_SI128(x, y)
Let x be a signed integer quadword.
Let y indicate the preferred sign code.

Return the signed integer value x in packed decimal format.

```plaintext
if x < 0 then do
    x ← ~x + 1
    sign ← 0x000D
end
else
    sign ← (y=0) ? 0x000C : 0x000F

result ← 0
shcnt ← 4

do while (x > 0)
    digit ← x % 10
    result ← result | (digit<<shcnt)
    x ← x ÷ 10
    shcnt ← shcnt + 4
end

return result | sign
```

bcd_INCREMENT(result)
Increments the magnitude of the packed decimal value x by 1.

bcd_SUBTRACT(x, y, z)
Let x and y be 31-digit signed decimal values.

Performs a signed decimal subtract of y from x.

If the unbounded result is equal to zero, eq_flag is set to 1. Otherwise, eq_flag is set to 0.
If the unbounded result is greater than zero, gt_flag is set to 1. Otherwise, gt_flag is set to 0.
If the unbounded result is less than zero, lt_flag is set to 1. Otherwise, lt_flag is set to 0.

If the magnitude of the unbounded result is greater than 10^{31-1}, ox_flag is set to 1. Otherwise, ox_flag is set to 0.

If the unbounded result is greater than or equal to zero, the sign code of the result is set to 0b1100 if z=0.
If the unbounded result is greater than or equal to zero, the sign code of the result is set to 0b1111 if z=1.
If the unbounded result is less than zero, the sign code of the result is set to 0b1101.

The low-order 31 digits of the unbounded result magnitude concatenated with the sign code are returned.

If either operand is an invalid encoding of a signed decimal value, the result returned is undefined and inv_flag is set to 1 and lt_flag, gt_flag and eq_flag are set to 0. Otherwise, inv_flag is set to 0.
bfp32_ADD(x, y)

x is a binary floating-point value represented in single-precision format.
y is a binary floating-point value represented in single-precision format.

If x is a QNaN, the result is x.
Otherwise, if x is an SNaN, the result is x converted to a QNaN.
Otherwise, if y is a QNaN, the result is y.
Otherwise, if y is an SNaN, the result is y converted to a QNaN.
Otherwise, if x and y are infinities having opposite signs, the result is the single-precision standard QNaN.
Otherwise, if x is an Infinity, the result is x.
Otherwise, if y is an Infinity, the result is y.
Otherwise, the result is the sum, x added to y, rounded to the nearest single-precision value.

Return the result represented in single-precision format.

bfp32_CONVERT_FROM_SI32(x, y)

Let x be a 32-bit signed integer value.

sign ← X.bit[0]
exp ← 32 + 127
frac.bit[0] ← x.bit[0]
frac.bit[1:32] ← x.bit[0:31]

if frac=0 return 0x0000_0000     // Zero operand
if sign=1 then frac = ~frac + 1

do while (frac.bit[0]=0)
   frac ← frac << 1
   exp ← exp - 1
end

lsb ← frac.bit[23]
gbit ← frac.bit[24]
xbit ← frac.bit[25:32]!=0
inc ← (lsb & gbit) | (gbit & xbit)
frac.bit[0:23] ← frac.bit[0:23] + inc
if carry_out=1 then exp ← exp + 1

result.bit[0] ← sign
result.bit[1:8] ← exp - y

return result
\[\textbf{bfp32\_CONVERT\_FROM\_UI32}(x, y)\]

\(x\) is a 32-bit unsigned integer value.

\[
\begin{align*}
\exp & \leftarrow 31 + 127 \\
\frac{} & \leftarrow x.\text{bit}[0:31] \\
\text{if } \frac{}=0 \text{ return } 0x0000_0000 \text{ // Zero} \\
\text{do while } \frac{}=0 \\
\frac{} & \leftarrow \frac{} << 1 \\
\exp & \leftarrow \exp - 1 \\
\text{end} \\
\text{lsb} & \leftarrow \frac{}.\text{bit}[23] \\
\text{gbit} & \leftarrow \frac{}.\text{bit}[24] \\
x\text{bit} & \leftarrow \frac{}.\text{bit}[25:31]!=0 \\
\text{inc} & \leftarrow (\text{lsb} \& \text{gbit}) | (\text{gbit} \& x\text{bit}) \\
\frac{}.\text{bit}[0:23] & \leftarrow \frac{}.\text{bit}[0:23] + \text{inc} \\
\text{if carry\_out}=1 \text{ then } \exp & \leftarrow \exp + 1 \\
\text{result}.\text{bit}[0] & \leftarrow 0b0 \\
\text{result}.\text{bit}[1:8] & \leftarrow \exp - y \\
\text{result}.\text{bit}[9:31] & \leftarrow \frac{}.\text{bit}[1:23] \\
\text{return result}
\end{align*}
\]

\[\textbf{bfp32\_LOG\_BASE2\_ESTIMATE}(x)\]

\(x\) is a floating-point value represented in single-precision format.

Returns a floating-point estimate of the base 2 logarithm of \(x\), represented in single-precision format.

\[\textbf{bfp32\_MAXIMUM}(x, y)\]

\(x\) is a floating-point value represented in single-precision format.
\(y\) is a floating-point value represented in single-precision format.

Returns the largest value of \(x\) and \(y\), represented in single-precision format.
- The maximum of \(+0.0\) and \(-0.0\) is \(+0.0\).
- The maximum of any value and a NaN is a QNaN.

\[\textbf{bfp32\_MINIMUM}(x, y)\]

\(x\) is a floating-point value represented in single-precision format.
\(y\) is a floating-point value represented in single-precision format.

Returns the smallest value of \(x\) and \(y\), represented in single-precision format.
- The minimum of \(+0.0\) and \(-0.0\) is \(-0.0\).
- The minimum of any value and a NaN is a QNaN.
**bfp32_MULTIPLY_ADD**(x, z, y)

- x is a binary floating-point value represented in single-precision format.
- y is a binary floating-point value represented in single-precision format.
- z is a binary floating-point value represented in single-precision format.

If x is a QNaN, return x.
Otherwise, if x is an SNaN, the result is x converted to a QNaN.
Otherwise, if y is a QNaN, the result is y.
Otherwise, if y is an SNaN, the result is y converted to a QNaN.
Otherwise, if z is a QNaN, the result is z.
Otherwise, if z is an SNaN, the result is z converted to a QNaN.
Otherwise, if x is an Infinity and z is a Zero, the result is the single-precision standard QNaN.
Otherwise, if x is a Zero and z is an Infinity, the result is the single-precision standard QNaN.
Otherwise, if the product, x multiplied by z, and y are Infinities having opposite signs, the result is the single-precision standard QNaN.
Otherwise, the result is the sum of the product, x multiplied by z, added to y, rounded to the nearest single-precision value.

Return the result represented in single-precision format.

**bfp32_NEGATIVE_MULTIPLY_SUBTRACT**(x, z, y)

- x is a binary floating-point value represented in single-precision format.
- y is a binary floating-point value represented in single-precision format.
- z is a binary floating-point value represented in single-precision format.

If x is a QNaN, the result is x.
Otherwise, if x is an SNaN, the result is x converted to a QNaN.
Otherwise, if y is a QNaN, the result is y.
Otherwise, if y is an SNaN, the result is y converted to a QNaN.
Otherwise, if z is a QNaN, the result is z.
Otherwise, if z is an SNaN, the result is z converted to a QNaN.
Otherwise, if x is an Infinity and z is a Zero, the result is the single-precision standard QNaN.
Otherwise, if x is a Zero and z is an Infinity, the result is the single-precision standard QNaN.
Otherwise, if the product, x multiplied by z, and y are Infinities having the same signs, the result is the single-precision standard QNaN.
Otherwise, the result is the difference of the product, x multiplied by z, subtracted by y, then rounded to the nearest single-precision value, and then negated.

Return the result represented in single-precision format.

**bfp32_POWER2_ESTIMATE**(x)

- x is a floating-point value represented in single-precision format.

Returns a floating-point estimate of 2 raised to the power of x, represented in single-precision format.

**bfp32_RECIPROCAL_ESTIMATE**(x)

- x is a floating-point value represented in single-precision format.

Returns a floating-point estimate of the reciprocal of x, represented in single-precision format.

**bfp32_RECIPROCAL_SQRT_ESTIMATE**(x)

- x is a floating-point value represented in single-precision format.

Returns a floating-point estimate of the reciprocal of the square root of x, represented in single-precision format.
bfp32_ROUND_TO_INTEGER_CEIL(x)

x is a floating-point value represented in single-precision format.

Returns the smallest floating-point integer that is greater than or equal to x, represented in single-precision format.

bfp32_ROUND_TO_INTEGER_FLOOR(x)

x is a floating-point value represented in single-precision format.

Returns the largest floating-point integer that is less than or equal to x, represented in single-precision format.

bfp32_ROUND_TO_INTEGER_NEAR(x)

x is a floating-point value represented in single-precision format.

Returns the floating-point integer that is nearest to x (in case of a tie, the even single-precision floating-point integer is used), represented in single-precision format.

bfp32_ROUND_TO_INTEGER_TRUNC(x)

x is a floating-point value represented in single-precision format.

Returns the largest floating-point integer that is less than or equal to x if x>0, or the smallest floating-point integer that is greater than or equal to x if x>0, or represented in single-precision format.

bfp32_SUBTRACT(x,y)

x is a binary floating-point value represented in single-precision format.
y is a binary floating-point value represented in single-precision format.

If x is a QNaN, the result is x.
Otherwise, if x is an SNaN, the result is x converted to a QNaN.
Otherwise, if y is a QNaN, the result is y.
Otherwise, if y is an SNaN, the result is y converted to a QNaN.
Otherwise, if x and y are infinities having the same signs, the result is the single-precision standard QNaN.
Otherwise, if x is an infinity, the result is x.
Otherwise, if y is an infinity, the result is y.
Otherwise, the result is the difference, x subtracted by y, rounded to the nearest single-precision value.

Return the result represented in single-precision format.

bool_COMPARE_GE_BFP32(x,y)

x is a floating-point value represented in the single-precision format.
y is a floating-point value represented in the single-precision format.

Returns the value 1 if x is greater than or equal to y. Otherwise, returns the value 0.

bool_COMPARE_GT_BFP32(x,y)

x is a floating-point value represented in the single-precision format.
y is a floating-point value represented in the single-precision format.

Returns the value 1 if x is greater than y. Otherwise, returns the value 0.
bool_COMPARE_EQ_BFP32(x, y)
  x is a floating-point value represented in the single-precision format.
  y is a floating-point value represented in the single-precision format.

  Returns the value 1 if x is equal to y. Otherwise, returns the value 0.

bool_COMPARE_LE_BFP32(x, y)
  x is a floating-point value represented in the single-precision format.
  y is a floating-point value represented in the single-precision format.

  Returns the value 1 if x is less than or equal to y. Otherwise, returns the value 0.

CHOP8(x)
  Returns rightmost 8 bits of x padded on the left with zeros if necessary.

CHOP16(x)
  Returns rightmost 16 bits of x padded on the left with zeros if necessary.

CHOP32(x)
  Returns rightmost 32 bits of x padded on the left with zeros if necessary.

CHOP64(x)
  Returns rightmost 64 bits of x padded on the left with zeros if necessary.

CHOP128(x)
  Returns rightmost 128 bits of x padded on the left with zeros if necessary.

Clamp(x, y, z)
  x is interpreted as a signed integer. If the value of x is less than y, then the value y is returned, else if the value of x is greater than z, the value z is returned, else the value x is returned.

  if x < y then
    result ← y
  else if x > z then
    result ← z
  else
    result ← x

EXTS(x)
  Result of extending x on the left with copies of bit 0 of x to form a signed integer value having unbounded range.

EXTSB(x)
  Result of extending x on the left with copies of bit 0 of x to form an 8-bit signed integer value.

EXTS16(x)
  Result of extending x on the left with copies of bit 0 of x to form a 16-bit signed integer value.

EXTS32(x)
  Result of extending x on the left with copies of bit 0 of x to form a 32-bit signed integer value.

EXTS64(x)
  Result of extending x on the left with copies of bit 0 of x to form a 64-bit signed integer value.

EXTS128(x)
  Result of extending x on the left with copies of bit 0 of x to form a 128-bit signed integer value.

EXTZ(x)
  Result of extending x on the left with 0s to form a positive signed integer value having unbounded range.
EXTZB(x)
Result of extending x on the left with 0s to form an 8-bit unsigned integer value.

EXTZ16(x)
Result of extending x on the left with 0s to form a 16-bit unsigned integer value.

EXTZ32(x)
Result of extending x on the left with 0s to form a 32-bit unsigned integer value.

EXTZ64(x)
Result of extending x on the left with 0s to form a 64-bit unsigned integer value.

EXTZ128(x)
Result of extending x on the left with 0s to form a 128-bit unsigned integer value.

InvMixColumns(x)
\[
\text{InvMixColumns}(x) = \begin{cases}
\text{result.word}[c].\text{byte}[0] &= 0x0E \times x.\text{word}[c].\text{byte}[0] \oplus 0x0B \times x.\text{word}[c].\text{byte}[1] \\
\text{result.word}[c].\text{byte}[1] &= 0x09 \times x.\text{word}[c].\text{byte}[0] \oplus 0x0E \times x.\text{word}[c].\text{byte}[1] \\

result.word[c].byte[3] = 0x03•x.word[c].byte[0] ^ x.word[c].byte[1] ^ x.word[c].byte[2] ^ 0x02•x.word[c].byte[3] 
end 
return(result)

The GF(2^8) multiply of 0x02•x can be expressed in minimized terms as the following.

\[
\text{product}.bit[0] = x.bit[1] \\
\text{product}.bit[7] = x.bit[0]
\]

The GF(2^8) multiply of 0x03•x can be expressed in minimized terms as the following.

\[
\text{product}.bit[0] = x.bit[0] ^ x.bit[1] \\
\text{product}.bit[7] = x.bit[0]
\]

qword_bit_splat(x)
x is a 1-bit value.
Return the concatenation of 128 copies of x.

ROTL128(x, y)
Let x be a 128-bit integer value.
Let y be an integer value.
Return x rotated left by y bits.
**ShiftRows(x)**

```plaintext
result.word[0].byte[0] = x.word[0].byte[0]
result.word[1].byte[0] = x.word[1].byte[0]
result.word[2].byte[0] = x.word[2].byte[0]
result.word[3].byte[0] = x.word[3].byte[0]

result.word[0].byte[1] = x.word[1].byte[1]
result.word[3].byte[1] = x.word[0].byte[1]

result.word[1].byte[3] = x.word[0].byte[3]
```

**si8_CLAMP(x)**

Let \( x \) be a signed integer value.

Return the value \( x \) in 8-bit signed integer format.

- If the value of the element is greater than \( 2^{7} - 1 \) the result saturates to \( 2^{7} - 1 \) and \( \text{sat\_flag} \) is set to 1.
- If the value of the element is less than \( -2^{7} \) the result saturates to \( -2^{7} \) and \( \text{sat\_flag} \) is set to 1.

**si16_CLAMP(x)**

Let \( x \) be a signed integer value.

Return the value \( x \) in 16-bit signed integer format.

- If the value of the element is greater than \( 2^{15} - 1 \) the result saturates to \( 2^{15} - 1 \) and \( \text{SAT} \) is set to 1.
- If the value of the element is less than \( -2^{15} \) the result saturates to \( -2^{15} \) and \( \text{SAT} \) is set to 1.

**si32_CLAMP(x)**

Let \( x \) be a signed integer value.

Return the value \( x \) in 32-bit signed integer format.

- If the value of the element is greater than \( 2^{31} - 1 \) the result saturates to \( 2^{31} - 1 \) and \( \text{SAT} \) is set to 1.
- If the value of the element is less than \( -2^{31} \) the result saturates to \( -2^{31} \) and \( \text{SAT} \) is set to 1.
si32_CONVERT_FROM_BFP32(x, y)

Let \( x \) be a single-precision floating-point value.
Let \( y \) be an unsigned integer value.

\[
\begin{align*}

6.3 Vector Facility Registers

6.3.1 Vector-Scalar Registers

The Vector instructions described in Chapter 6 are defined to operate on the higher-numbered 32 Vector-Scalar Registers (VSRs 32-63), formerly known as Vector Registers (VRs 0-31). See Figure 98. All computations and other data manipulation are performed on data residing in VSRs 32-63, and results are placed into one of VSRs 32-63.

Depending on the instruction, the contents of a VSR are interpreted as a sequence of equal-length elements (bytes, halfwords, or words) or as a quadword. Each of the elements is aligned within the VSR, as shown in Figure 97. Many instructions perform a given operation in parallel on all elements in a VSR. Depending on the instruction, a byte, halfword, or word element can be interpreted as a signed-integer, an unsigned-integer, or a logical value; a word element can also be interpreted as a single-precision floating-point value. In the instruction descriptions, phrases like “signed-integer word element” are used as shorthand for “word element, interpreted as a signed-integer”.

Load and Store instructions are provided that transfer a byte, halfword, word, or quadword between storage and a VSR.

6.3.2 Vector Status and Control Register

The Vector Status and Control Register (VSCR) is a special 32-bit register (not an SPR) that is read and written in a manner similar to the FPSCR in the Power ISA scalar floating-point unit. Special instructions (mfvscr and mtvscr) are provided to move the VSCR from and to a VSR. When moved to or from a VSR, the 32-bit VSCR is right justified in the 128-bit VSR. When moved to a VSR, bits 0:95 of the VSR are cleared (set to 0).

The bit definitions for the VSCR are as follows.

VSCR
Vector Saturation ($\text{SAT}$)

Every vector instruction having “Saturate” in its name implicitly sets this bit to 1 if any result of that instruction “saturates”; see Section 6.8. $\text{mtvscr}$ can alter this bit explicitly. This bit is sticky; that is, once set to 1 it remains set to 1 until it is set to 0 by an $\text{mtvscr}$ instruction.

After the $\text{mtvscr}$ instruction executes, the result in the target VSR will be architecturally precise. That is, it will reflect all updates to the $\text{SAT}$ bit that could have been made by vector instructions logically preceding it in the program flow, and further, it will not reflect any $\text{SAT}$ updates that may be made to it by vector instructions logically following it in the program flow. To implement this, processors may choose to make the $\text{mtvscr}$ instruction execution serializing within the vector unit, meaning that it will stall vector instruction execution until all preceding vector instructions are complete and have updated the architectural machine state. This is permitted in order to simplify implementation of the sticky status bit ($\text{SAT}$) which would otherwise be difficult to implement in an out-of-order execution machine. The implication of this is that reading the VSCR can be much slower than typical Vector instructions, and therefore care must be taken in reading it, as advised in Section 6.5.1, to avoid performance problems.

The $\text{mtvscr}$ is context synchronizing. This implies that all Vector instructions logically preceding an $\text{mtvscr}$ in the program flow will execute in the architectural context ($\text{NJ}$ mode) that existed prior to completion of the $\text{mtvscr}$, and that all instructions logically following the $\text{mtvscr}$ will execute in the new context ($\text{NJ}$ mode) established by the $\text{mtvscr}$.

## 6.3.3 VR Save Register

The VR Save Register ($\text{VRSAVE}$) is a 32-bit register in the fixed-point processor provided for application and operating system use; see Section 3.2.3.

### Programming Note

$\text{VRSAVE}$ can be used to indicate which VSRs are currently being used by a program. If this is done, the operating system could save only those VSRs when an “interrupt” occurs (see Book III), and could restore only those VSRs when resuming the interrupted program.

If this approach is taken it must be applied rigorously; if a program fails to indicate that a given VSR is in use, software errors may occur that will be difficult to detect and correct because they are timing-dependent.

Some operating systems save and restore $\text{VRSAVE}$ only for programs that also use other VSRs.
6.4 Vector Storage Access Operations

The Vector Storage Access instructions provide the means by which data can be copied from storage to a VSR or from a VSR to storage. Instructions are provided that access byte, halfword, word, and quadword storage operands. These instructions differ from the fixed-point and floating-point Storage Access instructions in that vector storage operands are assumed to be aligned, and vector storage accesses are performed as if the appropriate number of low-order bits of the specified effective address (EA) were zero. For example, the low-order bit of EA is ignored for halfword Vector Storage Access instructions, and the low-order four bits of EA are ignored for quadword Vector Storage Access instructions. The effect is to load or store the storage operand of the specified length that contains the byte addressed by EA.

If a storage operand is unaligned, additional instructions must be used to ensure that the operand is correctly placed in a VSR or in storage. Instructions are provided that shift and merge the contents of two VSRs, such that an unaligned quadword storage operand can be copied between storage and the VSRs in a relatively efficient manner.

As shown in Figure 97, the elements in VSRs are numbered; the high-order (or most significant) byte element is numbered 0 and the low-order (or least significant) byte element is numbered 15. The numbering affects the values that must be placed into the permute control vector for the Vector Permute instruction in order for that instruction to achieve the desired effects, as illustrated by the examples in the following subsections.

A vector quadword Load instruction for which the effective address (EA) is quadword-aligned places the byte in storage addressed by EA into byte element 0 of the target VSR, the byte in storage addressed by EA+1 into byte element 1 of the target VSR, etc. Similarly, a vector quadword Store instruction for which the EA is quadword-aligned places the contents of byte element 0 of the source VSR into the byte in storage addressed by EA, the contents of byte element 1 of the source VSR into the byte in storage addressed by EA+1, etc.

Figure 100 shows an aligned quadword in storage. Figure 101 shows the result of loading that quadword into a VSR or, equivalently, shows the contents that must be in a VSR if storing that VSR is to produce the storage contents shown in Figure 100.

When an aligned byte, halfword, or word storage operand is loaded into a VSR, the element (byte, halfword, or word respectively) that receives the data is the element that would have received the data had the entire aligned quadword containing the storage operand addressed by EA been loaded. Similarly, when a byte, halfword, or word element in a VSR is stored into an aligned storage operand (byte, halfword, or word respectively), the element selected to be stored is the element that would have been stored into the storage operand addressed by EA had the entire VSR been stored to the aligned quadword containing the storage operand addressed by EA. (Byte storage operands are always aligned.)

For aligned byte, halfword, and word storage operands, if the corresponding element number is known when the program is written, the appropriate Vector Splat and Vector Permute instructions can be used to copy or replicate the data contained in the storage operand after loading the operand into a VSR. An example of this is given in the Programming Note for Vector Splat; see page 292. Another example is to replicate the element across an entire VSR before storing it into an arbitrary aligned storage operand of the same length; the replication ensures that the correct data are stored regardless of the offset of the storage operand in its aligned quadword in storage.

6.4.1 Accessing Unaligned Storage Operands

Figure 102 shows an unaligned quadword storage operand that spans two aligned quadwords. In the remainder of this section, the aligned quadword that contains the most significant bytes of the unaligned quadword is called the most significant quadword (MSQ) and the aligned quadword that contains the least significant bytes of the unaligned quadword is called the least significant quadword (LSQ). Because the Vector Storage Access instructions ignore the low-order bits of the effective address, the unaligned quadword cannot be transferred between storage and a VSR using a single instruction. The remainder of this section gives examples of accessing unaligned quadword storage operands. Similar sequences can be used to access unaligned halfword and word storage operands.

**Programming Note**

The sequence of instructions given below is one approach that can be used to load the unaligned quadword shown in Figure 102 into a VSR. In Figure 103 Vhi and Vlo are the VSRs that will receive the most significant quadword and least significant quadword respectively. VSR[VRT+32] is the target VSR.

After the two quadwords have been loaded into Vhi and Vlo, using Load Vector Indexed instructions, the alignment is performed by shifting the 32-byte quantity Vhi || Vlo left by an amount determined by the address of the first byte of the desired data. The shifting is done using a Vector Permute instruction for which the permute control vector is generated by a Load Vector for Shift Left instruction. The Load Vector for Shift Left instruction uses the same address specification as the Load Vector Indexed instruction that loads the Vhi register; this is the address of the desired unaligned quadword.

The following sequence of instructions copies the unaligned quadword storage operand into register Vt.

```assembly
# Assumptions:
# Rb != 0 and contents of Rb = 0xB
lvx    Vhi,0,Rb       # load MSQ
lvsr   Vp,0,Rb        # set permute control vector
addi   Rb,Rb,16       # address of LSQ
lvx    Vlo,0,Rb       # load LSQ
vperm  V1s,Vhi,Vlo,Vp # align the data
```

The procedure for storing an unaligned quadword is essentially the reverse of the procedure for loading one. However, a read-modify-write sequence is required that inserts the source quadword into two aligned quadwords in storage. The quadword to be stored is assumed to be in Vs; see Figure 103. The contents of Vs are shifted right and split into two parts, each of which is merged (using a Vector Select instruction) with the current contents of the two aligned quadwords (MSQ and LSQ) that will contain the most significant bytes and least significant bytes, respectively, of the unaligned quadword. The resulting two quadwords are stored using Store Vector Indexed instructions. A Load Vector for Shift Right instruction is used to generate the permute control vector that is used for the shifting. A single register is used for the “shifted” contents; this is possible because the “shifting” is done by means of a right rotation. The rotation is accomplished by specifying Vs for both components of the Vector Permute instruction. In addition, the same permute control vector is used on a sequence of 1s and 0s to generate the mask used by the Vector Select instructions that do the merging.

The following sequence of instructions copies the contents of Vs into an unaligned quadword in storage.

```assembly
# Assumptions:
# Rb != 0 and contents of Rb = 0xB
lvx    Vhi,0,Rb       # load current MSQ
lvsr   Vp,0,Rb        # set permute control vector
addi   Rb,Rb,16       # address of LSQ
lvx    Vlo,0,Rb       # load current LSQ
vspltsb Vls,-1        # generate the select mask bits
vspltsb Vls,0
vperm  Vmask,Vls,Vls,Vp # generate the select mask
vperm  Vmask,Vls,Vlo,Vp # rotate the data
vsel   Vlo,VS,VS,Vp   # insert LSQ component
vsel   Vhi,Vhi,VS,Vmask # insert MSQ component
stvx   Vlo,0,Rb       # store LSQ
addi   Rb,Rb,-16      # address of MSQ
stvx   Vhi,0,Rb       # store MSQ
```
6.5 Vector Integer Operations

Many of the instructions that produce fixed-point integer results have the potential to compute a result value that cannot be represented in the target format. When this occurs, this unrepresentable intermediate value is converted to a representable result value using one of the following methods.

1. The high-order bits of the intermediate result that do not fit in the target format are discarded. This method is used by instructions having names that include the word "Modulo".

2. The intermediate result is converted to the nearest value that is representable in the target format (i.e., to the minimum or maximum representable value, as appropriate). This method is used by instructions having names that include the word "Saturate". An intermediate result that is forced to the minimum or maximum representable value as just described is said to "saturate".

An instruction for which an intermediate result saturates causes $\text{SAT}$ to be set to 1; see Section 6.3.2.

3. If the intermediate result includes non-zero fraction bits it is rounded up to the nearest fixed-point integer value. This method is used by the six Vector Average Integer instructions and by the Vector Multiply-High-Round-Add Signed Halfword Saturate instruction. The latter instruction then uses method 2, if necessary.

---

**Programming Note**

Because $\text{SAT}$ is sticky, it can be used to detect whether any instruction in a sequence of “Saturate”-type instructions produced an inexact result due to saturation. For example, the contents of the VSCR can be copied to a VSR (mfvscr), bits other than $\text{SAT}$ can be cleared in the VSR (vand with a constant), the result can be compared to zero setting CR6 (vcmpequb), and a branch can be taken according to whether $\text{SAT}$ was set to 1 (Branch Conditional that tests CR field 6).

Testing $\text{SAT}$ after each “Saturate”-type instruction would degrade performance considerably. Alternative techniques include the following:

- Retain sufficient information at “checkpoints” that the sequence of computations performed between one checkpoint and the next can be redone (more slowly) in a manner that detects exactly when saturation occurs. Test $\text{SAT}$ only at checkpoints, or when redoing a sequence of computations that saturated.

- Perform intermediate computations using an element length sufficient to prevent saturation, and then use a Vector Pack Integer Saturate instruction to pack the final result to the desired length. (Vector Pack Integer Saturate causes results to saturate if necessary, and sets $\text{SAT}$ to 1 if any result saturates.)
6.5.1 Integer Saturation

Saturation occurs whenever the result of a saturating instruction does not fit in the result field. Unsigned saturation clamps results to zero (0) on underflow and to the maximum positive integer value ($2^{n-1}$, e.g. 255 for byte fields) on overflow. Signed saturation clamps results to the smallest representable negative number ($-2^{n-1}$, e.g. -128 for byte fields) on underflow, and to the largest representable positive number ($2^{n-1}-1$, e.g. +127 for byte fields) on overflow.

In most cases, the simple maximum/minimum saturation performed by the vector instructions is adequate. However, sometimes, e.g. in the creation of very high quality images, more complex saturation functions must be applied. To support this, the Vector facility provides a mechanism for detecting that saturation has occurred. The VSCR has a bit, SAT, which is set to a one (1) anytime any field in a saturating instruction saturates. SAT can only be cleared by explicitly writing zero to it. Thus SAT accumulates a summary result of any integer overflow or underflow that occurs on a saturating instruction.

Borderline cases that generate results equal to saturation values, for example unsigned $0+0=0$ and unsigned byte $1+254=255$, are not considered saturation conditions and do not cause SAT to be set.

SAT can be set by the following types of instructions:

- Move To VSCR
- Vector Add Integer with Saturation
- Vector Subtract Integer with Saturation
- Vector Multiply-Add Integer with Saturation
- Vector Multiply-Sum with Saturation
- Vector Sum-Across with Saturation
- Vector Pack with Saturation
- Vector Convert to Fixed-point with Saturation

Note that only instructions that explicitly call for "saturation" can set SAT. “Modulo” integer instructions and floating-point arithmetic instructions never set SAT.

--- Programming Note ---

The SAT state can be tested and used to alter program flow by moving the VSCR to a VSR (with mfvscr), then masking out bits 0:126 (to clear undefined and reserved bits) and performing a vector compare equal-to unsigned byte w/record (vcmpequb) with zero to get a testable value into the condition register for consumption by a subsequent branch.

Since mfvscr will be slow compared to other Vector instructions, reading and testing SAT after each instruction would be prohibitively expensive. Therefore, software is advised to employ strategies that minimize checking SAT. For example: checking SAT periodically and backtracking to the last checkpoint to identify exactly which field in which instruction saturated; or, working in an element size sufficient to prevent any overflow or underflow during intermediate calculations, then packing down to the desired element size as the final operation (the vector pack instruction saturates the results and updates SAT when a loss of significance is detected).
6.6 Vector Floating-Point Operations

6.6.1 Floating-Point Overview

Unless \( \|J\| = 1 \) (see Section 6.3.2), the floating-point model provided by the Vector Facility conforms to The Java Language Specification (hereafter referred to as “Java”), which is a subset of the default environment specified by the IEEE standard (i.e., by ANSI/IEEE Standard 754-1985, “IEEE Standard for Binary Floating-Point Arithmetic”). For aspects of floating-point behavior that are not defined by Java but are defined by the IEEE standard, vector floating-point conforms to the IEEE standard. For aspects of floating-point behavior that are defined neither by Java nor by the IEEE standard but are defined by the “C9X Floating-Point Proposal” (hereafter referred to as “C9X”), vector floating-point conforms to C9X.

The single-precision floating-point data format, value representations, and computational models defined in Chapter 4, “Floating-Point Facility” on page 131 apply to vector floating-point except as follows.

- In general, no status bits are set to reflect the results of floating-point operations. The only exception is that \( \text{SAT} \) may be set by the Vector Convert To Fixed-Point Word instructions.

- With the exception of the two Vector Convert To Fixed-Point Word instructions and three of the four Vector Round to Floating-Point Integer instructions, all vector floating-point instructions that round use the rounding mode Round to Nearest.

- Floating-point exceptions (see Section 6.6.2) cannot cause the system error handler to be invoked.

Programmed Note

If a function is required that is specified by the IEEE standard, is not supported by the Vector Facility, and cannot be emulated satisfactorily using the functions that are supported by the Vector Facility, the functions provided by the Floating-Point Facility should be used; see Chapter 4.

6.6.2 Floating-Point Exceptions

The following floating-point exceptions may occur during execution of vector floating-point instructions.

- NaN Operand Exception
- Invalid Operation Exception
- Zero Divide Exception
- Log of Zero Exception
- Overflow Exception
- Underflow Exception

If an exception occurs, a result is placed into the corresponding target element as described in the following subsections. This result is the default result specified by Java, the IEEE standard, or C9X, as applicable.

Recall that denormalized source values are treated as if they were zero when \( \|J\| = 1 \). This has the following consequences regarding exceptions.

- Exceptions that can be caused by a zero source value can be caused by a denormalized source value when \( \|J\| = 1 \).

- Exceptions that can be caused by a nonzero source value cannot be caused by a denormalized source value when \( \|J\| = 1 \).

6.6.2.1 NaN Operand Exception

A NaN Operand Exception occurs when a source value for any of the following instructions is a NaN.

- A vector instruction that would normally produce floating-point results
- Either of the two Vector Convert To Fixed-Point Word instructions
- Any of the four Vector Floating-Point Compare instructions

The following actions are taken:

If the vector instruction would normally produce floating-point results, the corresponding result is a source NaN selected as follows. In all cases, if the selected source NaN is a Signaling NaN it is converted to the corresponding Quiet NaN (by setting the high-order bit of the fraction field to 1) before being placed into the target element.
if the element in VSR[VRA+32] is a NaN then the result is that NaN else if the element in VSR[VRB+32] is a NaN then the result is that NaN else if the element in VSR[VRC+32] is a NaN then the result is that NaN else if Invalid Operation exception (Section 6.6.2.2) then the result is the QNaN 0x7FC0_0000

If the instruction is either of the two Vector Convert To Fixed-Point Word instructions, the corresponding result is 0x0000_0000. SAT is not affected.

If the instruction is Vector Compare Bounds Floating-Point, the corresponding result is 0xC000_0000.

If the instruction is one of the other Vector Floating-Point Compare instructions, the corresponding result is 0x0000_0000.

**6.6.2.2 Invalid Operation Exception**

An Invalid Operation Exception occurs when a source value or set of source values is invalid for the specified operation. The invalid operations are:

- Magnitude subtraction of infinities
- Multiplication of infinity by zero
- Reciprocal square root estimate of a negative, nonzero number or -infinity.
- Log base 2 estimate of a negative, nonzero number or -infinity.

The corresponding result is the QNaN 0x7FC0_0000.

**6.6.2.3 Zero Divide Exception**

A Zero Divide Exception occurs when a Vector Reciprocal Estimate Floating-Point or Vector Reciprocal Square Root Estimate Floating-Point instruction is executed with a source value of zero.

The corresponding result is an infinity, where the sign is the sign of the source value.

**6.6.2.4 Log of Zero Exception**

A Log of Zero Exception occurs when a Vector Log Base 2 Estimate Floating-Point instruction is executed with a source value of zero.

The corresponding result is -Infinity.

**6.6.2.5 Overflow Exception**

An Overflow Exception occurs under either of the following conditions.

- For a vector instruction that would normally produce floating-point results, the magnitude of what would have been the result if the exponent range were unbounded exceeds that of the largest finite floating-point number for the target floating-point format.

- For either of the two Vector Convert To Fixed-Point Word instructions, either a source value is an infinity or the product of a source value and $2^{UIM}$ is a number too large in magnitude to be represented in the target fixed-point format.

The following actions are taken:

1. If the vector instruction would normally produce floating-point results, the corresponding result is an infinity, where the sign is the sign of the intermediate result.

2. If the instruction is Vector Convert To Unsigned Fixed-Point Word Saturate, the corresponding result is 0xFFFF_FFFF if the source value is a positive number or +infinity, and is 0x0000_0000 if the source value is a negative number or -infinity. SAT is set to 1.

3. If the instruction is Vector Convert To Signed Fixed-Point Word Saturate, the corresponding result is 0x7FFF_FFFF if the source value is a positive number or +infinity, and is 0x8000_0000 if the source value is a negative number or -infinity. SAT is set to 1.

**6.6.2.6 Underflow Exception**

An Underflow Exception can occur only for vector instructions that would normally produce floating-point results. It is detected before rounding. It occurs when a nonzero intermediate result computed as though both the precision and the exponent range were unbounded is less in magnitude than the smallest normalized floating-point number for the target floating-point format.

The following actions are taken:

1. If $NJ = 0$, the corresponding result is the value produced by denormalizing and rounding the intermediate result.

2. If $NJ = 1$, the corresponding result is a zero, where the sign is the sign of the intermediate result.
6.7 Vector Storage Access Instructions

The Vector Storage Access instructions compute the effective address (EA) of the storage to be accessed as described in Section 1.10.3, “Effective Address Calculation” on page 29. The low-order bits of the EA that would correspond to an unaligned storage operand are ignored.

The Load Vector Element Indexed and Store Vector Element Indexed instructions transfer a byte, halfword, or word element between storage and a VSR. The Load Vector Indexed and Store Vector Indexed instructions transfer an aligned quadword between storage and a VSR.

6.7.1 Storage Access Exceptions

Storage accesses will cause the system data storage error handler to be invoked if the program is not allowed to modify the target storage (Store only), or if the program attempts to access storage that is unavailable.
6.7.2 Vector Load Instructions

The aligned byte, halfword, word, or quadword in storage addressed by EA is loaded into VSR[VRT+32].

Programming Note

The Load Vector Element instructions load the specified element into the same location in the target register as the location into which it would be loaded using the Load Vector instruction.

Load Vector Element Byte Indexed X-form

\texttt{lvebx VRT,RA,RB}

if MSR.VEC=0 then Vector_Unavailable()

\[EA \leftarrow \begin{cases} \text{GPR}[RA] & \text{if RA} \neq 0 \\ 0 & \text{otherwise} \end{cases} + \text{GPR}[RB] \]

Register Data Layout for \texttt{lxvx} & \texttt{lxvl}

\begin{verbatim}
src1src2result
\hline
GPR[RA]GPR[RB]VSR[VRT+32]
\end{verbatim}

Programming Note

On some implementations, the hint provided by the \texttt{lvxl} instruction and the corresponding hint provided by the \texttt{stvxl} instruction are applied to the entire cache block containing the specified quadword. On such implementations, the effect of the hint may be to cause that cache block to be considered a likely candidate for replacement when space is needed in the cache for a new block. Thus, on such implementations, the hint should be used with caution if the cache block containing the quadword also contains data that may be needed by the program in the near future. Also, the hint may be used before the last reference in a sequence of references to the quadword if the subsequent references are likely to occur sufficiently soon that the cache block containing the quadword is not likely to be displaced from the cache before the last reference.
6.7.3 Vector Store Instructions

Some portion or all of the contents of $VSR\{VRS+32\}$ are stored into the aligned byte, halfword, word, or quadword in storage addressed by $EA$.

Programming Note

The Store Vector Element instructions store the specified element into the same storage location as the location into which it would be stored using the Store Vector instruction.

Store Vector Element Byte Indexed X-form

$$\text{stvebx VRS,RA,RB}$$

1. If $VSR.VEC=0$ then $\text{Vector\_Unavailable()}$

   $$EA \leftarrow ((RA=0) ? 0 : \text{GPR}[RA]) + \text{GPR}[RB]$$

   $$eb \leftarrow EA.\text{bit}[60:63]$$

2. If Big-Endian byte ordering then

   $$\text{MEM}(EA,1) \leftarrow VSR\{VRS+32\}.\text{byte}[eb]$$

3. Else

   $$\text{MEM}(EA,1) \leftarrow VSR\{VRS+32\}.\text{byte}[15-eb]$$

Let $EA$ be the sum of the contents of $\text{GPR}[RA]$, or 0 if $RA=0$, and the contents of $\text{GPR}[RB]$.

Let $eb$ be bits $60:63$ of $EA$.

If Big-Endian byte ordering is used for the storage access, the contents of byte $eb$ of $VSR\{VRS+32\}$ are placed in the byte in storage at address $EA$.

If Little-Endian byte ordering is used for the storage access, the contents of byte $15-eb$ of $VSR\{VRS+32\}$ are placed in the byte in storage at address $EA$.

Special Registers Altered:

None

Programming Note

Unless bits $60:63$ of the address are known to match the byte offset of the subject byte element in $VSR\{VRS+32\}$, software should use $\text{Vector Splat}$ to splat the subject byte element before performing the store.

Register Data Layout for stvebx

See the Programming Note for the \text{lvxl} instruction on page 271.
6.7.4 Vector Alignment Support Instructions

Programming Note

The `lvsl` and `lvsr` instructions can be used to create the permute control vector to be used by a subsequent `vperm` instruction (see page 296). Let \( X \) and \( Y \) be the contents of \( \text{VSR}[\text{VRA}+32] \) and \( \text{VSR}[\text{VRB}+32] \) specified by the `vperm`. The control vector created by `lvsl` causes the `vperm` to select the high-order 16 bytes of the result of shifting the 32-byte value \( X || Y \) left by \( s_1 \) bytes. The control vector created by `lvsr` causes the `vperm` to select the low-order 16 bytes of the result of shifting \( X || Y \) right by \( s_2 \) bytes.

Programming Note

Examples of uses of `lvsl`, `lvsr`, and `vperm` to load and store unaligned data are given in Section 6.4.1. These instructions can also be used to rotate or shift the contents of a VSR left (`lvsl`) or right (`lvsr`) by \( s_1 \) bytes. For rotating, the VSR to be rotated should be specified as both \( \text{VSR}[\text{VRA}+32] \) and \( \text{VSR}[\text{VRB}+32] \) for `vperm`. For shifting left, \( \text{VSR}[\text{VRB}+32] \) for `vperm` should be a register containing all zeros and \( \text{VSR}[\text{VRA}+32] \) should contain the value to be shifted, and vice versa for shifting right.

    src ← VSR[VRB+32].hword[i]
    VSR[VRT+32].word[i].byte[0] ← EXT8(src.bit[0])
    VSR[VRT+32].word[i].byte[1] ← EXTZ(src.bit[1:5])
end

For each integer value \(i\) from 0 to 3, do the following.

The contents of halfword element \(i\) of VSR[VRB+32] are unpacked as follows.

- sign-extend bit 0 of the halfword to 8 bits
- zero-extend bits 1:5 of the halfword to 8 bits
- zero-extend bits 6:10 of the halfword to 8 bits
- zero-extend bits 11:15 of the halfword to 8 bits

The result is placed in word element \(i\) of VSR[VRT+32].

\end{array}
\]

Programming Note

The source and target elements can be considered to be 16-bit and 32-bit “pixels” respectively, having the formats described in the Programming Note for the Vector Pack Pixel instruction on page 278.

Programming Note

Notice that the unpacking done by the Vector Unpack Pixel instructions does not reverse the packing done by the Vector Pack Pixel instruction. Specifically, if a 16-bit pixel is unpacked to a 32-bit pixel which is then packed to a 16-bit pixel, the resulting 16-bit pixel will not, in general, be equal to the original 16-bit pixel (because, for each channel except the first, Vector Unpack Pixel inserts high-order bits while Vector Pack Pixel discards low-order bits).
### 6.8.3 Vector Merge Instructions

6.8.5 Vector Permute Instruction

The Vector Permute instruction allows any byte in two source VSRs to be copied to any byte in the target VSR. The bytes in a third source VSR specify from which byte in the first two source VSRs the corresponding target byte is to be copied. The contents of the third source VSR are sometimes referred to as the “permute control vector”.

Vector Permute VA-form

\[
\begin{align*}
\text{vperm} & \quad \text{VRT, VRA, VRB, VRC} \\
\text{if MSR.VEC}=0 & \quad \text{then VectorUnavailable()} \\
vsrc.[0] & \quad \leftarrow \text{VSR[VRA+32]} \\
vsrc.[1] & \quad \leftarrow \text{VSR[VRB+32]} \\
\text{do } i = 0 \text{ to } 15 & \\
\text{index} & \quad \leftarrow \text{VSR[VRC+32].byte}[i].\text{bit}[3:7] \\
\text{VSR[VRT+32].byte}[i] & \quad \leftarrow \text{src.byte}[\text{index}] \\
\text{end}
\end{align*}
\]

Let the source vector be the concatenation of the contents of \text{VSR[VRA+32]} followed by the contents of \text{VSR[VRB+32]}.

For each integer value \(i\) from 0 to 15, do the following.

Let \text{index} be the value specified by bits 3:7 of byte element \(i\) of \text{VSR[VRC+32]}.

The contents of byte element \text{index} of \text{src} are placed into byte element \(i\) of \text{VSR[VRT+32]}.

Special Registers Altered: None

Programming Note

See the Programming Notes with the Load Vector for Shift Left and Load Vector for Shift Right instructions on page 276 for examples of uses of \text{vperm}.

Register Data Layout for vperm & vpermr

6.8.7 Vector Shift Instructions

The Vector Shift instructions rotate or shift the contents of a VSR or a pair of VSRs left or right by a specified number of bytes (vslo, vsro, vsldoi) or bits (vsl, vsr). Depending on the instruction, this "shift count" is specified either by the contents of a VSR or by an immediate field in the instruction. In the former case, 7 bits of the shift count register give the shift count in bits ($0 \leq \text{count} \leq 127$). Of these 7 bits, the high-order 4 bits give the number of complete bytes by which to shift and are used by vslo and vsro; the low-order 3 bits give the number of remaining bits by which to shift and are used by vsl and vsr.

### Vector Shift Left Double by Bit Immediate VN-form

```plaintext
vsldbi VRT,VRA,VRB,SH
```

- **if MSR.VEC=0 then Vector_Unavailable()**
- vsrc.qword[0] ← VSR[VRA+32]
- vsrc.qword[1] ← VSR[VRB+32]
- VSR[VRT+32] ← vsrc.bit[SH:SH+127]

Let vsrc be the contents of VSR[VRA+32] concatenated with the contents of VSR[VRB+32].

The contents of bits SH:SH+127 of vsrc are placed into VSR[VRT+32].

**SH** can be any integer value between 0 and 7.

**Special Registers Altered:**

None

### Vector Shift Left Double by Octet Immediate VA-form

```plaintext
vsldoi VRT,VRA,VRB,SHB
```

- **if MSR.VEC=0 then Vector_Unavailable()**
- vsrc.qword[0] ← VSR[VRA+32]
- vsrc.qword[1] ← VSR[VRB+32]

Let vsrc be the contents of VSR[VRA+32] concatenated with the contents of VSR[VRB+32].

Bytes SHB:SHB+15 of vsrc are placed into VSR[VRT+32].

**Special Registers Altered:**

None

---

**Programming Note**

A pair of these instructions, specifying the same shift count register, can be used to shift the contents of a VSR left or right by the number of bits (0-127) specified in the shift count register. The following example shifts the contents of register Vx left by the number of bits specified in register Vy and places the result into register Vz.

vslo Vz, Vx, Vy
vspltb Vy, Vy, 15
vsl Vz, Vz, Vy

Chapter 6. Vector Facility

Version 3.1

Assume $vSRC$ contains a vector of packed 7-bit values, $A$ located in bits 0:6, $B$ located in bits 7:13, $C$ located in bits 14:20, etc..

```c
# vSRC = { 0bAAAAAAAB, 0bBBBBBBCC, 0bCCCCCDDD, 0bDDDDEEEE,
#          0bEEEFFFFF, 0bGGGGGGGG, 0bHHHHHHHH, 0bIIIIIIIIJ, 
#          0bJJJJJJKK, 0bKKKKKLLL, 0bLLLLMMMM, 0bMMMNNNNN, 
#          0bNNOOOOOO, 0bOPPPPPPP, 0bQQQQQQQR, 0bRRRRRRSS }; 
```

Assume the following registers are pre-loaded as follows,

```c
# vSHCNT1 = { 0x01, 0x02, 0x03, 0x04, 0x05, 0x06, 0x07, 0x07, 
#             0x07, 0x07, 0x07, 0x07, 0x07, 0x07, 0x07, 0x07 }; 
# vSHCNT2 = { 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x01, 
#             0x02, 0x03, 0x04, 0x05, 0x06, 0x07, 0x07, 0x07 }; 
# vSHCNT3 = { 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 
#             0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x01, 0x02 }; 
# vMASK = { 0x7F, 0x7F, 0x7F, 0x7F, 0x7F, 0x7F, 0x7F, 0x7F, 
#          0x7F, 0x7F, 0x7F, 0x7F, 0x7F, 0x7F, 0x7F, 0x7F }; 
```

The leftmost seven packed 7-bit values can be unpacked into byte elements 0 to 6 using $\text{vsrv}$ with $vSHCNT1$.

```c
vsrv vTMP1, vSRC, vSHCNT1
# vTMP1 = { 0b0AAAAAAA, 0bABBBBBBB, 0bBCCCCCCC, 0bCDDDDDDD, 
#          0bDEEEEEEE, 0bEFFFFFFF, 0bFGGGGGGG, 0bGHHHHHHH, 
#          0bHIIIIIII, 0bIJJJJJJJ, 0bJKKKKKKK, 0bKLLLLLLL, 
#          0bLMMMMMMM, 0bMNNNNNNN, 0bNOOOOOOO, 0bPPPPPPPQ }; 
```

The next seven packed 7-bit values can then be unpacked into byte elements 7 to 13 using $\text{vsrv}$ with $vSHCNT2$.

```c
vsrv vTMP2, vTMP1, vSHCNT2
# vTMP2 = { 0b0AAAAAAA, 0bABBBBBBB, 0bBCCCCCCC, 0bCDDDDDDD, 
#          0bDEEEEEEE, 0bEFFFFFFF, 0bFGGGGGGG, 0bGHHHHHHH, 
#          0bHIIIIIII, 0bIJJJJJJJ, 0bJKKKKKKK, 0bKLLLLLLL, 
#          0bLMMMMMMM, 0bMNNNNNNN, 0bNOOOOOOO, 0bPPPPPPPQ }; 
```

The next two packed 7-bit values can then be unpacked into byte elements 14 to 15 using $\text{vsrv}$ with $vSHCNT3$.

```c
vsrv vTMP3, vTMP2, vSHCNT3
# vTMP3 = { 0b0AAAAAAA, 0bABBBBBBB, 0bBCCCCCCC, 0bCDDDDDDD, 
#          0bDEEEEEEE, 0bEFFFFFFF, 0bFGGGGGGG, 0bGHHHHHHH, 
#          0bHIIIIIII, 0bIJJJJJJJ, 0bJKKKKKKK, 0bKLLLLLLL, 
#          0bLMMMMMMM, 0bMNNNNNNN, 0bNOOOOOOO, 0bOPPPPPPQ }; 
```

The most-significant bit in each byte element is masked off to produce a vector of sixteen unsigned byte elements.

```c
vand vTMP4, vTMP3, vMASK
# vTMP4 = { 0b0AAAAAAA, 0b0BBBBBBB, 0b0CCCCCCC, 0b0DDDDDDD, 
#          0b0EEEEEEE, 0b0FFFFFFF, 0b0GGGGGGG, 0b0HHHHHHH, 
#          0b0IIIIIII, 0b0JJJJJJJ, 0b0KKKKKKK, 0b0LLLLLLL, 
#          0b0MNNNNNN, 0b0000000D, 0b0000000P }; 
```

The vector of sixteen unsigned byte elements can be further unpacked to two vectors of eight unsigned halfword elements using a $\text{vupkhsb}$ and a $\text{vupklsb}$.

```c
vupkhsb vTMP5, vTMP4
# vTMP5 = { 0b0000000D, 0bAAAAAAA, 0b0000000D, 0bBBBBBBB, ... }; 
vupklsb vTMP6, vTMP4
# vTMP6 = { 0b0000000D, 0bIIIIIII, 0b0000000D, 0bJJJJJJJ, ... }; 
```

The resultant two vectors of eight unsigned halfword elements can then be further unpacked to four vectors of four unsigned word elements using two $\text{vupkhsh}$ and two $\text{vupklsh}$ instructions.

```c
vupkhsh vRESULT0, vTMP5
# vRESULT0 = { 0b0000000D, 0b0000000D, 0b0000000D, 0bAAAAAAA, ... }; 
vupklsh vRESULT1, vTMP5
# vRESULT1 = { 0b0000000D, 0b0000000D, 0b0000000D, 0bBBBBBBB, ... }; 
vupkhsh vRESULT2, vTMP6
# vRESULT2 = { 0b0000000D, 0b0000000D, 0b0000000D, 0bIIIIIII, ... }; 
vupklsh vRESULT3, vTMP6
# vRESULT3 = { 0b0000000D, 0b0000000D, 0b0000000D, 0bJJJJJJJ, ... }; 
```
6.8.8 Vector Extract Element Instructions

6.8.8.1 Vector Extract Element to VSR using Immediate-specified Index Instructions

**Vector Extract Unsigned Byte to VSR using immediate-specified index VX-form**

\[ \text{vextractub} \ VRT, VRB, UIM \]

- If MSR.VEC=0 then Vector_Unavailable()
- \( \text{src} \leftarrow VSR[VRB+32].\text{byte}[UIM] \)
- \( VSR[VRT+32].\text{dword}[0] \leftarrow \text{EXTZ64} (\text{src}) \)
- \( VSR[VRT+32].\text{dword}[1] \leftarrow 0x0000_0000_0000_0000 \)

The contents of byte element \( UIM \) of \( VSR[VRB+32] \) are placed into bits 56:63 of \( VSR[VRT+32] \). The contents of the remaining byte elements of \( VSR[VRT+32] \) are set to 0.

</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>26</td>
<td>32</td>
</tr>
</tbody>
</table>

```plaintext
if MSR.VEC=0 then Vector_Unavailable()

do i = 0 to 7
	src1 ← EXTS(VSR[VRA+32].hword[i])
	src2 ← EXTS(VSR[VRB+32].hword[i])
	src3 ← EXTS(VSR[VRC+32].hword[i])

result ← ((src1 × src2)) >> 15 + src3
VSR[VRT+32].hword[i] ← si16_CLAMP(result)
VSCR.SAT ← sat_flag
end
```

For each integer value \( i \) from 0 to 7, do the following.

The signed integer value in halfword element \( i \) of VSR[VRA+32] is multiplied by the signed integer value in halfword element \( i \) of VSR[VRB+32], producing a 32-bit signed integer product.

Bits 0:16 of the product are added to the signed integer value in halfword element \( i \) of VSR[VRC+32].

- If the intermediate result is greater than \( 2^{15} \), the result saturates to \( 2^{15} - 1 \) and SAT is set to 1.
- If the intermediate result is less than \( -2^{15} \), the result saturates to \( -2^{15} \) and SAT is set to 1.

The low-order 16 bits of the result are placed into halfword element \( i \) of VSR[VRT+32].

Special Registers Altered:

- SAT

#### Vector Multiply-High-Round-Add Signed Halfword Saturate VA-form

```plaintext
vmhraddshs VRT, VRA, VRB, VRC
```

<table>
<thead>
<tr>
<th>4</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>26</th>
<th>33</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>6</td>
<td>11</td>
<td>16</td>
<td>21</td>
<td>26</td>
<td>33</td>
</tr>
</tbody>
</table>

```plaintext
if MSR.VEC=0 then Vector_Unavailable()

do i = 0 to 7
	src1 ← EXTS(VSR[VRA+32].hword[i])
	src2 ← EXTS(VSR[VRB+32].hword[i])
	src3 ← EXTS(VSR[VRC+32].hword[i])

result ← (((src1 × src2) + 0x0000_4000) >> 15) + src3
VSR[VRT+32].hword[i] ← si16_CLAMP(result)
VSCR.SAT ← sat_flag
end
```

For each integer value \( i \) from 0 to 7, do the following.

The signed integer value in halfword element \( i \) of VSR[VRA+32] is multiplied by the signed integer value in halfword element \( i \) of VSR[VRB+32], producing a 32-bit signed integer product.

The value 0x0000_4000 is added to the product.

Bits 0:16 of the 32-bit sum are added to the signed integer value in halfword element \( i \) of VSR[VRT+32].

- If the intermediate result is greater than \( 2^{15} - 1 \), the result saturates to \( 2^{15} - 1 \) and SAT is set to 1.
- If the intermediate result is less than \( -2^{15} \), the result saturates to \( -2^{15} \) and SAT is set to 1.

The low-order 16 bits of the result are placed into halfword element \( i \) of VSR[VRT+32].

Special Registers Altered:

- SAT

#### Register Data Layout for vmhaddshs & vmhraddshs

Let \( \text{dividend} \) be the signed integer value in doubleword element \( i \) of VSR[VRA+32], shifted left by 64 bits.

Let \( \text{divisor} \) be the signed integer value in doubleword element \( i \) of VSR[VRB+32].

\( \text{dividend} \) is divided by \( \text{divisor} \).

The quotient is the unique signed integer that satisfies

\[
\text{dividend} = (\text{quotient} \times \text{divisor}) + \text{remainder}
\]

where \( 0 \leq r < |\text{divisor}| \) if the dividend is nonnegative, and \( -|\text{divisor}| < r \leq 0 \) if the dividend is negative.

If the quotient cannot be represented in 64 bits, or if an attempt is made to perform the division, \(<\text{anything}> + 0\), the quotient is undefined.

The quotient is placed into doubleword element \( i \) of VSR[VRT+32].

6.9.3 Vector Integer Compare Instructions

The Vector Integer Compare instructions compare two VSRs element by element, interpreting the elements as unsigned or signed-integers depending on the instruction, and set the corresponding element of the target VSR to all ‘1s if the relation being tested is true and to all ‘0s if the relation being tested is false.

If Rc=1 CR Field 6 is set to reflect the result of the comparison, as follows.

---

**Programming Note**

vcmpqub[, vcmpquh[, vcmpquw[, and vcmpqud[], can be used for unsigned or signed-integers.

---

**Vector Compare Equal Unsigned Byte VC-form**

6.9.4 Vector Logical Instructions

Extended mnemonics for vector logical operations

Extended mnemonics are provided that use the Vector OR and Vector NOR instructions to copy the contents of one VSR to another, with and without complementing. These are shown as examples with the two instructions.

Vector Move Register

Several vector instructions can be coded in a way such that they simply copy the contents of one VSR to another. An extended mnemonic is provided to convey the idea that no computation is being performed but merely data movement (from one register to another).

The following instruction copies the contents of register Vy to register Vx.

\[ \text{vmr} \ Vx, Vy \quad \text{(equivalent to:} \quad \text{vor} \ Vx, Vy, Vy) \]

Vector Complement Register

The Vector NOR instruction can be coded in a way such that it complements the contents of one VSR and places the result into another VSR. An extended mnemonic is provided that allows this operation to be coded easily.

The following instruction complements the contents of register Vy and places the result into register Vx.

\[ \text{vnot} \ Vx, Vy \quad \text{(equivalent to:} \quad \text{vnor} \ Vx, Vy, Vy) \]

Vector Logical AND VX-form

\[ \text{vand} \ VRT, VRA, VRB \]

6.9.5.2 Vector Integer Rotate Left then AND with Mask Instructions

### Vector Rotate Left Word then AND with Mask VX-form

`vrlwnm VRT,VRA,VRB`

For each integer value \( i \) from 0 to 3, do the following.

Let \( \text{src1} \) be the contents of word element \( i \) of \( \text{VSR}[\text{VRA}+32] \).

Let \( \text{src2} \) be the contents of word element \( i \) of \( \text{VSR}[\text{VRB}+32] \).

Let \( \text{mb} \) be the contents of bits 11:15 of \( \text{src2} \).

Let \( \text{me} \) be the contents of bits 19:23 of \( \text{src2} \).

Let \( \text{sh} \) be the contents of bits 27:31 of \( \text{src2} \).

\( \text{src1} \) is rotated left \( \text{sh} \) bits.

A mask is generated having 1-bits from bit \( \text{mb} \) through bit \( \text{me} \) and 0-bits elsewhere.

The rotated data are ANDed with the generated mask.

The result is placed into word element \( i \) of \( \text{VSR}[\text{VRT}+32] \).

**Special Registers Altered:**

None

**Vector Rotate Left Quadword then AND with Mask VX-form**

Let src1 be the contents of VSR[VRA+32].
Let src2 be the contents of VSR[VRB+32].
Let mb be the contents of bits 41:47 of src2.
Let me be the contents of bits 49:55 of src2.
Let sh be the contents of bits 57:63 of src2.

src1 is rotated left sh bits.

A mask is generated having 1-bits from bit mb through bit me and 0-bits elsewhere.

The rotated data are ANDed with the generated mask.

The result is placed into VSR[VRT+32].

```plaintext
if MSR.VEC=0 then Vector_Unavailable()

do i = 0 to 3
    src1 ← VSR[VRA+32].word[i]
    src2 ← VSR[VRB+32].word[i]
    src3 ← VSR[VRC+32].word[i]
    result ← bfp32_MULTIPLY_ADD(src1, src3, src2)
    VSR[VRT+32].word[i] ← result
end
```

For each integer value $i$ from 0 to 3, do the following.

Let $src1$ be the single-precision floating-point value in word element $i$ of $VSR[VRA+32]$.

Let $src2$ be the single-precision floating-point value in word element $i$ of $VSR[VRB+32]$.

Let $src3$ be the single-precision floating-point value in word element $i$ of $VSR[VRC+32]$.

$src1$ is multiplied by $src3$.

$src2$ is added to the infinitely-precise product.

The intermediate result is rounded to the nearest single-precision floating-point number and placed into word element $i$ of $VSR[VRT+32]$.

Special Registers Altered:
None

**Programming Note**

To use a multiply-add to perform an IEEE or Java compliant multiply, the addend must be $-0.0$. This is necessary to insure that the sign of a zero result will be correct when the product is $-0.0$ ($+0.0 + -0.0 = +0.0$, and $-0.0 + -0.0 = -0.0$). When the sign of a resulting $0.0$ is not important, then $+0.0$ can be used as an addend which may, in some cases, avoid the need for a second register to hold a $-0.0$ in addition to the integer floating-point $+0.0$ that may already be available.

6.10.4 Vector Floating-Point Compare Instructions

The Vector Floating-Point Compare instructions compare two VSRs word element by word element, interpreting the elements as single-precision floating-point numbers. With the exception of the Vector Compare Bounds Floating-Point instruction, they set the target VSR, and CR Field 6 if \( Rc = 1 \), in the same manner as do the Vector Integer Compare instructions; see Section 6.9.3.

The Vector Compare Bounds Floating-Point instruction sets the target VSR, and CR Field 6 if \( Rc = 1 \), to indicate whether the elements in \( VSR[VRA+32] \) are within the bounds specified by the corresponding element in \( VSR[VRB+32] \), as explained in the instruction description. A single-precision floating-point value \( x \) is said to be "within the bounds" specified by a single-precision floating-point value \( y \) if \(-y \leq x \leq y\).

Let \( \text{src1} \) be the single-precision floating-point value in element \( i \) of \( VSR[VRA+32] \).

Let \( \text{src2} \) be the single-precision floating-point value in element \( i \) of \( VSR[VRB+32] \).

\( \text{src1} \) is compared to \( \text{src2} \).

A 2-bit value is formed that indicates whether \( \text{src1} \) is within the bounds specified by \( \text{src2} \), as follows.

- Bit 0 of the 2-bit value is set to 0 if \( \text{src1} \) is less than or equal to \( \text{src2} \), and is set to 1 otherwise.

- Bit 1 of the 2-bit value is set to 0 if \( \text{src1} \) is greater than or equal to the negation of \( \text{src2} \), and is set to 1 otherwise.

The 2-bit value is placed into the high-order two bits of word element \( i \) of \( VSR[VRT+32] \) and the remaining bits of element \( i \) are set to 0.

If \( Rc = 1 \), CR field 6 is set as follows.

**Bit Description**

0 Set to 0
1 Set to 0
2 Set to indicate whether all four elements in \( VSR[VRA+32] \) are within the bounds specified by the corresponding element in \( VSR[VRB+32] \), otherwise set to 0.
3 Set to 0

**Special Registers Altered:**

\( \text{CR field 6} \) ............................................... (if \( Rc = 1 \))

**Programming Note**

Each single-precision floating-point value in \( VSR[VRB+32] \) should be non-negative; if it is negative, the corresponding element in \( VSR[VRA+32] \) will necessarily be out of bounds.

One exception to this is when the value of an element in \( VSR[VRB+32] \) is -0.0 and the value of the corresponding element in \( VSR[VRA+32] \) is either +0.0 or -0.0 +0.0 and -0.0 compare equal to -0.0.

do i = 0 to 3
    src ← VSR[VRB+32].word[i]
    VSR[VRT+32].word[i] ← bfp32_POWER2_ESTIMATE(src)
end

For each integer value i from 0 to 3, do the following.
The single-precision floating-point estimate of 2 raised to the power of single-precision floating-point element i of VSR[VRB+32] is placed into word element i of VSR[VRT+32].

Let x be any single-precision floating-point input value. Unless x < -146 or the single-precision floating-point result of computing 2 raised to the power x would be a zero, an infinity, or a QNaN, the estimate has a relative error in precision no greater than one part in 16. The most significant 12 bits of the estimate’s significand are monotonic. An integral input value returns an integral value when the result is representable.

The result for various special cases of the source value is given below.

<table>
<thead>
<tr>
<th>Value</th>
<th>Result</th>

Vector Log Base 2 Estimate Floating-Point
VX-form

vlogefp VRT,VRB

if MSR.VEC=0 then Vector_Unavailable()

do i = 0 to 3
    src ← VSR[VRB+32].word[i]
    VSR[VRT+32].word[i] ← bfp32_LOG_BASE2_ESTIMATE(src)
end

For each integer value i from 0 to 3, do the following.
The single-precision floating-point estimate of the base 2 logarithm of single-precision floating-point element i of VSR[VRB+32] is placed into the corresponding word element i of VSR[VRT+32].

Let x be any single-precision floating-point input value. Unless |x-1| is less than or equal to 0.125 or the single-precision floating-point result of computing the base 2 logarithm of x would be an infinity or a QNaN, the estimate has an absolute error in precision (absolute value of the difference between the estimate and the infinitely precise value) no greater than $2^{-5}$. Under the same conditions, the estimate has a relative error in precision no greater than one part in 8.

The most significant 12 bits of the estimate's significand are monotonic. The estimate is exact if $x=2^y$, where y is an integer between -149 and +127 inclusive. Otherwise the value placed into the element of VSR[VRT+32] may vary between implementations, and between different executions on the same implementation.

The result for various special cases of the source value is given below.

<table>
<thead>
<tr>
<th>Value</th>
<th>Result</th>
</tr>

end

For each integer value \( i \) from 0 to 3, do the following.
The single-precision floating-point estimate of the reciprocal of single-precision floating-point element \( i \) of \( VSR[VRB+32] \) is placed into word element \( i \) of \( VSR[VRT+32] \).

Unless the single-precision floating-point result of computing the reciprocal of a value would be a zero, an infinity, or a QNaN, the estimate has a relative error in precision no greater than one part in 4096.

Note that results may vary between implementations, and between different executions on the same implementation.

The result for various special cases of the source value is given below.

6.11 Vector Exclusive-OR-based Instructions

6.11.1 Vector AES Instructions

This section describes a set of instructions that support the Federal Information Processing Standards Publication 197 Advanced Encryption Standard for encryption and decryption.

**Vector AES Cipher VX-form**

```plaintext
vcipher VRT,VRA,VRB
```

1. If MSR.VEC=0 then Vector_Unavailable()
2. `State ← VSR[VRA+32]`
3. `RoundKey ← VSR[VRB+32]`
4. `vtemp1 ← SubBytes(State)`
5. `vtemp2 ← ShiftRows(vtemp1)`
6. `vtemp3 ← MixColumns(vtemp2)`
7. `VSR[VRT+32] ← vtemp3 ^ RoundKey`

Let `State` be the contents of `VSR[VRA+32]`, representing the intermediate state array during AES cipher operation.

Let `RoundKey` be the contents of `VSR[VRB+32]`, representing the round key.

One round of an AES cipher operation is performed on the intermediate `State` array, sequentially applying the transforms, `SubBytes()`, `ShiftRows()`, `MixColumns()`, and `AddRoundKey()`, as defined in FIPS-197.

The result is placed into `VSR[VRT+32]`, representing the new intermediate state of the cipher operation.

6.11.3 Vector Binary Polynomial Multiplication Instructions

This section describes a set of binary polynomial multiply-sum instructions. Corresponding elements are multiplied and the exclusive-OR of each even-odd pair of products sum, useful for a variety of finite field arithmetic operations.

**Vector Polynomial Multiply-Sum Byte VX-form**

**vpmsumb**  
VRT,VRA,VRB

<table>
<thead>
<tr>
<th>0</th>
<th>4</th>
<th>6</th>
<th>11</th>
<th>16</th>
<th>21</th>
<th>31</th>
</tr>
</thead>
</table>

```
if MSR.VEC=0 then Vector_Unavailable() |

do i = 0 to 15
   prod[i].bit[0:14] ← 0
   srcA ← VSR[VRA+32].byte[i]
   srcB ← VSR[VRB+32].byte[i]
   do j = 0 to 7
      do k = 0 to j
         gbit ← srcA.bit[k] & srcB.bit[j-k]
         prod[i].bit[j] ← prod[i].bit[j] ^ gbit
      end
   end
   do j = 8 to 14
      do k = j-7 to 7
         gbit ← (srcA.bit[k] & srcB.bit[j-k])
         prod[i].bit[j] ← prod[i].bit[j] ^ gbit
      end
   end
   do i = 0 to 7
      VSR[VRT+32].hword[i] ← 0b0 || (prod[2×i] ^ prod[2×i+1])
   end
```

For each integer value \( i \) from 0 to 15, do the following.
Let \( \text{prod}[i] \) be the 15-bit result of a binary polynomial multiplication of the contents of byte element \( i \) of \( \text{VSR}[\text{VRA}+32] \) and the contents of byte element \( i \) of \( \text{VSR}[\text{VRB}+32] \).

For each integer value \( i \) from 0 to 7, do the following.
The exclusive-OR of \( \text{prod}[2\times i] \) and \( \text{prod}[2\times i+1] \) is placed in bits 1:15 of halfword element \( i \) of \( \text{VSR}[\text{VRT}+32] \). Bit 0 of halfword element \( i \) of \( \text{VSR}[\text{VRT}+32] \) is set to 0.

6.12 Vector Bit Manipulation Instructions

6.12.1 Vector Gather Bits Instructions

*Vector Gather Bits by Bytes by Doubleword VX-form*

Let \( s_r c \) be the contents of \( VSR[VRB+32] \), composed of two doubleword elements numbered 0 and 1.

Let each doubleword element be composed of eight bytes numbered 0 through 7.

An 8-bit \( \times \) 8-bit bit-matrix transpose is performed on the contents of each doubleword element of \( VSR[VRB+32] \) (see Figure 104).

For each integer value \( i \) from 0 to 1, do the following,

1. The contents of bit 0 of each byte of doubleword element \( i \) of \( VSR[VRB+32] \) are concatenated and placed into byte 0 of doubleword element \( i \) of \( VSR[VRT+32] \).
2. The contents of bit 1 of each byte of doubleword element \( i \) of \( VSR[VRB+32] \) are concatenated and placed into byte 1 of doubleword element \( i \) of \( VSR[VRT+32] \).
3. The contents of bit 2 of each byte of doubleword element \( i \) of \( VSR[VRB+32] \) are concatenated and placed into byte 2 of doubleword element \( i \) of \( VSR[VRT+32] \).
4. The contents of bit 3 of each byte of doubleword element \( i \) of \( VSR[VRB+32] \) are concatenated and placed into byte 3 of doubleword element \( i \) of \( VSR[VRT+32] \).
5. The contents of bit 4 of each byte of doubleword element \( i \) of \( VSR[VRB+32] \) are concatenated and placed into byte 4 of doubleword element \( i \) of \( VSR[VRT+32] \).
6. The contents of bit 5 of each byte of doubleword element \( i \) of \( VSR[VRB+32] \) are concatenated and placed into byte 5 of doubleword element \( i \) of \( VSR[VRT+32] \).
7. The contents of bit 6 of each byte of doubleword element \( i \) of \( VSR[VRB+32] \) are concatenated and placed into byte 6 of doubleword element \( i \) of \( VSR[VRT+32] \).
8. The contents of bit 7 of each byte of doubleword element \( i \) of \( VSR[VRB+32] \) are concatenated and placed into byte 7 of doubleword element \( i \) of \( VSR[VRT+32] \).

For each integer value i from 0 to 1, and for each integer value j from 0 to 7, do the following.

Let index be the contents of byte sub-element j of doubleword element i of VSR[VRB+32].

If index is less than 64, then the contents of bit index of doubleword i of VSR[VRA+32] are placed into bit 56+j of doubleword element i of VSR[VRT+32]. Otherwise, bit 56+j of doubleword element i of VSR[VRT+32] is set to 0.

The contents of bits 0:55 of doubleword element i of VSR[VRT+32] are set to 0.

Programming Note

The fact that the permuted bit is 0 if the corresponding index value exceeds 127 permits the permuted bits to be selected from a 256-bit quantity, using a single index register. For example, assume that the 256-bit quantity Q, from which the permuted bits are to be selected, is in registers v2 (high-order 128 bits of Q) and v3 (low-order 128 bits of Q), that the index values are in register v1, with each byte of v1 containing a value in the range 0:255, and that each byte of register v4 contains the value 128. The following code sequence selects eight permuted bits from Q and places them into the low-order byte of v6.

vbpermq v6, v1, v2  # select from high-order half of Q
vxor v0, v1, v4    # adjust index values
vbpermq v5, v0, v3  # select from low-order half of Q
vor v6, v6, v5     # merge the two selections

6.13.3 Vector Count Mask Bits Instructions

The Vector Count Mask Bits instructions count the number of true (or false) mask bits (bit 0 of each element) in a VSR and place the count in the leftmost byte of a GPR (i.e., can be used by Load VSX Vector with Length and Store Vector with Length).

**Vector Count Mask Bits Byte VX-form**

`vcntmbb RT,VRB,MP`

```
if MSR.VEC=0 then Vector_Unavailable()

count = 0
do i = 0 to 15
    count ← count + EXTZ8(VSR[VRB+32].byte[i].bit[0]=MP)
end

GPR[RT] ← count << 56
```

The number of byte elements having bit 0 set to the value `MP` in VSR[VRB+32] is placed into bits 0:7 of GPR[RT]. Bits 8:63 of GPR[RT] are set to 0.

**Special Registers Altered:**

None

**Register Data Layout for vcntmbb**

```
result | GPR[RT]
0   | 8  16  32  48  56  64  72  80  88  96 104 112 120 127
```

**Vector Count Mask Bits Halfword VX-form**

`vcntmbh RT,VRB,MP`

```
if MSR.VEC=0 then Vector_Unavailable()

count = 0
do i = 0 to 7
    count ← count + EXTZ64(VSR[VRB+32].hword[i].bit[0]=MP)
end

GPR[RT] ← count << 57
```

The number of halfword elements having bit 0 set to the value `MP` in VSR[VRB+32] is placed into bits 0:6 of GPR[RT]. Bits 7:63 of GPR[RT] are set to 0.

**Special Registers Altered:**

None

**Register Data Layout for vcntmbh**

```
result | GPR[RT]
0   | 16  32  48  56  64  72  80  88  96 104 112 120 127
```
**Vector Count Mask Bits Word VX-form**

\[
\begin{array}{cccccc}
\text{vcntmbw} & \text{RT} & \text{VRB} & \text{MP} & \text{VRB}+32 & \text{VRB}+32 \\
0 & 6 & 11 & 16 & 21 & 1602 \\
\end{array}
\]

\[
\text{if MSR.VEC=0 then Vector.Unavailable()}
\]

\[
\text{count} = 0
\]

\[
\text{do i = 0 to 3}
\]

\[
\text{count} \leftarrow \text{count} + \text{EXTZ64(VSR[VRB+32].word[i].bit[0]=MP)}
\]

\[
\text{end}
\]

\[
\text{GPR}[\text{RT}] \leftarrow \text{count} \ll 58
\]

The number of word elements having bit 0 set to the value \text{MP} in VSR[\text{VRB+32}] is placed into bits 0:5 of GPR[\text{RT}]. Bits 6:63 of GPR[\text{RT}] are set to 0.

6.15 Decimal Integer Instructions

A valid encoding of a packed decimal integer value requires the following properties.
- Each of the 31 4-bit digits of the operand’s magnitude (bits 0:123) must be in the range 0-9.
- The sign code (bits 124:127) must be in the range 10-15.

Source operands with sign codes of 0b1010, 0b1100, 0b1110, and 0b1111 are interpreted as positive values.

Source operands with sign codes of 0b1011 and 0b1101 are interpreted as negative values.

Positive and zero results are encoded with a either sign code of 0b1100 or 0b1111, depending on the preferred sign (indicated as an immediate operand).

Negative results are encoded with a sign code of 0b1101.

6.15.1 Decimal Integer Arithmetic Instructions

The Decimal Integer Arithmetic instructions operate on decimal integer values only in signed packed decimal format. Signed packed decimal format consists of 31 4-bit base-10 digits of magnitude and a trailing 4-bit sign code. Operations are performed as sign-magnitude, and produce a decimal result placed in a VSR (i.e., \texttt{bcdadd}, \texttt{bcdsub}).
### Decimal Add Modulo VX-form

Software should take care when interoperability with the Decimal Floating-Point facilities is required. The register format defined for 31-digit signed decimal values employed by \texttt{bcdadd} and \texttt{bcdsub} is a single 128-bit VSR. The register format defined for 31-digit signed decimal values employed by the Decimal Floating-Point instructions \texttt{ddedpdq} and \texttt{denbcdq} is a pair of 64-bit FPRs. \texttt{xxpermdi} can be used to convert between the two register formats as well as move data between the FPR and VSR halves of the Vector-Scalar Registers.

\texttt{gew} and \texttt{fmrgow} are provided to support direct move operations in 32-bit mode.

Programming Note

\texttt{bcdsub. vTmp,vA,vB,0} can be used to compare decimal operands \texttt{vA} and \texttt{vB}. Bits 0-2 of CR field 6 will be set to indicate \texttt{vA} is less than \texttt{vB} (LT), \texttt{vA} is greater than \texttt{vB} (GT), and \texttt{vA} is equal to \texttt{vB} (EQ).

\texttt{bcdsub. vTmp,vA,vA,0} can be used to test if an operand \texttt{vA} is an invalid encoding of a decimal value.

Programming Note

When bit 3 of CR field 6 is set to 1 by \texttt{bcdadd} or \texttt{bcdsub}, either an overflow occurred or one or both operands are not valid encodings of decimal values. Discerning whether an overflow occurred can be accomplished by performing the other decimal instruction on the operands. For example, if \texttt{bcdadd} caused bit 3 of CR field 6 to be set to 1, performing \texttt{bcdsub} on the same set of operands will cause bit 3 of CR field 6 to be set to 1 if and only if one or both of the operands is an invalid encoding. If bit 3 of CR field 6 is not set by \texttt{bcdsub}, then the \texttt{bcdadd} can be asserted to have overflowed. Likewise, \texttt{bcdadd} can be used in a similar manner to determine the cause of bit 3 of CR field 6 getting set by a \texttt{bcdsub}.
6.15.2 Decimal Integer Format Conversion Instructions

Decimal Convert From National VX-form

Let src be the national decimal value in VSR[VRB+32].

src is placed in VSR[VRT+32] in packed decimal format.

A valid encoding of a national decimal value requires the following.

- The contents of halfword 7 (sign code) must be either 0x002B or 0x002D.
- The contents of halfwords 0 to 6 must be in the range 0x0030 to 0x0039.

National decimal values having a sign code of 0x002B are interpreted as positive values.

National decimal values having a sign code of 0x002D are interpreted as negative values.

For each integer value i from 0 to 23, do the following.

The contents of nibble element i of VSR[VRT+32] are set to 0x0.

For each integer value i from 0 to 6, do the following.

The contents of nibble 3 of halfword element i of src are placed into nibble element i+24 of VSR[VRT+32].

For PS=0, the contents of nibble element 31 (i.e., sign code) of VSR[VRT+32] are set to 0xC for positive values and to 0xD for negative values.

For PS=1, the contents of nibble element 31 (i.e., sign code) of VSR[VRT+32] are set to 0xF for positive values and to 0xD for negative values.

CR field 6 is set to reflect src compared to zero.

If src is an invalid encoding of a national decimal value, the contents of VSR[VRT+32] are undefined and CR field 6 is set to 0b0001.

Decimal Convert From Zoned VX-form

Let \( \text{src} \) be the zoned decimal value in \( \text{VSR}[\text{VRB}+32] \).
\( \text{src} \) is placed in \( \text{VSR}[\text{VRT}+32] \) in packed decimal format.

When \( \text{PS}=0 \), do the following.

A valid encoding of a zoned decimal value requires the following.

- The contents of bits 0:3 of byte 15 (sign code) can be any value in the range \( 0x0 \) to \( 0xF \).
- The contents of bits 0:3 of bytes 0 to 14 must be the value \( 0x3 \).
- The contents of bytes 4:7 of bytes 0 to 15 must be a value in the range \( 0x0 \) to \( 0x9 \).

Zoned decimal values having a sign code of \( 0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xA, or 0xB \) are interpreted as positive values.

Zoned decimal values having a sign code of \( 0xA, 0xE, 0x7, 0xC, 0xD, 0x5, 0x6, \) or \( 0xF \) are interpreted as negative values.

When \( \text{PS}=1 \), do the following.

A valid encoding of a zoned decimal source operand requires the following.

- The contents of bits 0:3 of byte 15 (sign code) must be a value in the range \( 0xA \) to \( 0xF \).
- The contents of bits 0:3 of bytes 0 to 14 must be the value \( 0xF \).
- The contents of bytes 4:7 of bytes 0 to 15 must be a value in the range \( 0x0 \) to \( 0x9 \).

Zoned decimal source operands having a sign code of \( 0x0, 0x3, 0x8, 0x9, 0xA, \) or \( 0xB \) are interpreted as positive values.

Zoned decimal source operands having a sign code of \( 0xA, 0xC, 0xE, \) or \( 0xF \) are interpreted as negative values.

Positive packed decimal results are returned with a sign code of \( 0xC \).

Negative packed decimal results are returned with a sign code of \( 0xD \).

For each integer value \( i \) from 0 to 14,

- The contents of nibble element \( i \) of \( \text{VSR}[\text{VRT}+32] \) are set to \( 0x0 \).

For each integer value \( i \) from 0 to 15,

- The contents of nibble 1 of byte element \( i \) of \( \text{src} \) are placed into nibble element \( i+15 \) of \( \text{VSR}[\text{VRT}+32] \).

CR field 6 is set to reflect \( \text{src} \) compared to zero.

If \( \text{src} \) is an invalid encoding of a zoned decimal value, the contents of \( \text{VSR}[\text{VRT}+32] \) are undefined and CR field 6 is set to \( 0b00001 \).

Decimal Convert To National VX-form

src is placed into VSR[VRT+32] in national decimal format.

A valid encoding of a signed packed decimal value requires the following.

- The contents of nibble 31 (sign code) must be a value in the range 0xA to 0xF.
- The contents of each nibble 0-30 must be a value in the range 0x0 to 0x9.

Packed decimal values with sign codes of 0xA, 0xC, 0xE, or 0xF are interpreted as positive values.

Packed decimal values with sign codes of 0xB or 0xD are interpreted as negative values.

Values greater in magnitude than $10^7 - 1$ are too large to be represented in national decimal format.

For each integer value $i$ from 0 to 6, do the following.

- The value 0x003 is placed into nibbles 0:2 of halfword element $i$ of VSR[VRT+32].
- The contents of nibble element $i+24$ of VSR[VRT+32] are placed into nibble 3 of halfword element $i$ of VSR[VRT+32].

The contents of nibble element $i+24$ of VSR[VRT+32] are set to 0x002D for positive values and to 0x002B for negative values.

CR field 6 is set to reflect src compared to zero, including whether or not src is too large to be represented in national decimal format.

If src is an invalid encoding of a packed decimal value, the contents of VSR[VRT+32] are undefined and CR field 6 is set to 0b00001.

Version 3.1
### 6.15.4 Decimal Integer Shift and Round Instructions

#### Decimal Shift VX-form

Let $n$ be the signed integer value in byte element 7 of $VSR[VRA+32]$.

Let $src$ be the signed packed decimal value in $VSR[VRB+32]$.

A valid encoding of a signed packed decimal value requires the following.
- The contents of nibble 31 (sign code) must be a value in the range 0xA to 0xF.
- The contents of each nibble 0-30 must be a value in the range 0x0 to 0x9.

Packed decimal source operands with sign codes of 0xA, 0xC, 0xE, or 0xF are interpreted as positive values.

Packed decimal source operands with sign codes of 0xB or 0xD are interpreted as negative values.

If $n$ is greater than zero, $src$ is shifted left $n$ digits. Zeros are supplied to vacated digits on the right. If any non-zero digits are shifted out, an overflow occurs.

If $n$ is less than zero, $src$ is shifted right $-n$ digits. Zeros are supplied to vacated digits on the left.

If the packed decimal value in $VSR[VRB+32]$ is negative, the sign code of the result is set to 0b1101.

If the packed decimal value in $VSR[VRB+32]$ is positive, the sign code of the result is set to 0b1100 if $PS=0$ and is set to 0b1111 if $PS=1$.

The shifted result is placed into $VSR[VRT+32]$.

CR field 6 is set to reflect $src$ compared to zero, including whether or not significant digits were shifted out when the shift count is positive (i.e., left shift operation).

If $src$ is an invalid encoding of a packed decimal value, the contents of $VSR[VRT+32]$ are undefined and CR field 6 is set to 0b0001.

**Special Registers Altered:**
- CR field 6

Decimal Shift & Round VX-form

**bcdsr.** VRT, VRA, VRB, PS

Let \( n \) be the signed integer value in byte element 7 of VSR\([\text{VRA+32}]\).

Let \( src \) be the signed packed decimal value in VSR\([\text{VRB+32}]\).

A valid encoding of a signed packed decimal source operand requires the following:
- The contents of nibble 31 (sign code) must be a value in the range 0xA to 0xF.
- The contents of each nibble 0-30 must be a value in the range 0x0 to 0x9.

Packed decimal source operands with sign codes of 0xA, 0xC, 0xE, or 0xF are interpreted as positive values.

Packed decimal source operands with sign codes of 0xB or 0xD are interpreted as negative values.

If \( n \) is greater than zero, \( src \) is shifted left \( n \) digits. Zeros are supplied to vacated digits on the right. If any non-zero digits are shifted out, an overflow occurs.

If \( n \) is less than zero, \( src \) is shifted right \(-n\) digits. Zeros are supplied to vacated digits on the left. If the value of the last nibble shifted out on the right was greater than or equal to 5, the magnitude of the result is incremented by 1.

If \( src \) is negative, the sign code of the result is set to 0b1101.

If \( src \) is positive, the sign code of the result is set to 0b1100 if \( PS=0 \) and is set to 0b1111 if \( PS=1 \).

The shifted and rounded result is placed into VSR\([\text{VRT+32}]\).

CR field 6 is set to reflect \( src \) compared to zero, including whether or not significant digits were shifted out when the shift count is positive (i.e., left shift operation).

If \( src \) is an invalid encoding of a packed decimal value, the contents of VSR\([\text{VRT+32}]\) are undefined and CR field 6 is set to 0b0001.

Special Registers Altered:
CR field 6

Chapter 6. Vector Facility 493
6.15.5 Decimal Integer Truncate Instructions

Decimal Truncate VX-form

Let \(\text{length}\) be the integer value in bits 48:63 of \(\text{VSR}[\text{VRA+32}]\).

Let \(\text{src}\) be the signed decimal value in \(\text{VSR}[\text{VRB+32}]\).

A valid encoding of a packed decimal source operand requires the following.

- The contents of nibble 31 (sign code) must be a value in the range \(0xA\) to \(0xF\).
- The contents of each nibble 0-30 must be a value in the range \(0x0\) to \(0x9\).

Packed decimal values with sign codes of \(0xA\), \(0xC\), \(0xE\), or \(0xF\) are interpreted as positive values.

Packed decimal values with sign codes of \(0xB\) or \(0xD\) are interpreted as negative values.

If \(\text{src}\) is negative, the sign code of the result is set to \(0b1101\).

If \(\text{src}\) is positive, the sign code of the result is set to \(0b1110\) if \(\text{PS}=0\) and is set to \(0b1111\) if \(\text{PS}=1\).

\(\text{src}\) is copied into \(\text{VSR}[\text{VRT+32}]\) with the leftmost \(\text{length}\) digits set to \(0b0000\). If any of the leftmost \(\text{length}\) digits of the signed decimal value in \(\text{VSR}[\text{VRB+32}]\) are non-zero, an overflow occurs.

CR field 6 is set to reflect \(\text{src}\) compared to zero, including whether or not significant digits were truncated.

If \(\text{src}\) is an invalid encoding of a packed decimal value, the contents of \(\text{VSR}[\text{VRT+32}]\) are undefined and CR field 6 is set to \(0b0001\).

Chapter 7. Vector-Scalar Extension Facility

7.1 Introduction

7.1.1 Overview of the Vector-Scalar Extension

Vector-Scalar Extension (VSX) provides facilities supporting vector and scalar binary floating-point operations. The following VSX features are provided to increase opportunities for vectorization.

- A unified register file, a set of Vector-Scalar Registers (VSR), supporting both scalar and vector operations is provided, eliminating the overhead of vector-scalar data transfer through storage.

- Support for word-aligned storage accesses for both scalar and vector operations is provided.

- Robust support for IEEE-754 for both vector and scalar floating-point operations is provided.

7.1.1.1 Combining the Floating-Point Registers (FPR) defined in Chapter 4. Floating-Point Facility and the Vector Registers (VR) defined in Chapter 6. Vector Facility provides additional registers to support more aggressive compiler optimizations for both vector and scalar operations. Compatibility with Floating-Point and Decimal Floating-Point Operations

The instruction sets defined in Chapter 4. Floating-Point Facility and Chapter 5. Decimal Floating-Point Facility retain their definition with one primary difference. The FPRs are mapped to doubleword element 0 of VSRs 0-31. The contents of doubleword 1 of the VSR corresponding to a source FPR specified by an instruction are ignored. The contents of doubleword 1 of a VSR corresponding to the target FPR specified by an instruction are set to 0.

7.1.1.2 Compatibility with Vector Operations

The instruction set defined in Chapter 6. Vector Facility, retains its definition with one primary difference. The VRs are mapped to VSRs 32-63.

Programming Note

Application binary interfaces extended to support VSX require special care of vector data written to VSRs 0-31 (i.e., VSRs corresponding to FPRs). Legacy scalar function calls employ doubleword-based loads and stores to preserve the contents of any nonvolatile registers. This has the adverse effect of not preserving the contents of doubleword 1 of these VSRs.

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.
7.2 VSX Registers

7.2.1 Vector-Scalar Registers

Sixty-four 128-bit VSRs are provided. See Figure 105. All VSX floating-point computations and other data manipulation are performed on data residing in Vector-Scalar Registers, and results are placed into a VSR.

Depending on the instruction, the contents of a VSR are interpreted as a sequence of equal-length elements (words or doublewords) or as a quadword. Each of the elements is aligned within the VSR, as shown in Figure 105. Many instructions perform a given operation in parallel on all elements in a VSR.

Depending on the instruction, a word element can be interpreted as a signed integer word (SW), an unsigned integer word (UW), a logical mask value (MW), or a single-precision floating-point value (SP); a doubleword element can be interpreted as a doubleword signed integer (SD), a doubleword unsigned integer (UD), a doubleword mask (DM), or a double-precision floating-point value (DP). In the instructions descriptions, phrases like signed integer word element are used as shorthand for word element, interpreted as a signed integer.

Load and Store instructions are provided that transfer a byte, a specified number of bytes (up to 16), a halfword, a word, a doubleword, or a quadword between storage and a VSR, or an octword between storage and a pair of VSRs.

![Figure 105: Vector-Scalar Registers](image)

![Figure 106: Vector-Scalar Register Elements](image)

7.2.1.1 Floating-Point Registers

Chapter 4. Floating-Point Facility provides 32 64-bit FPRs. Chapter 5. Decimal Floating-Point also employs FPRs in decimal floating-point (DFP) operations. When VSX is implemented, the 32 FPRs are mapped to doubleword 0 of VSRs 0-31. For example, FPR[0] is located in doubleword element 0 of VSR[0], FPR[1] is located in doubleword element 0 of VSR[1], and so forth.

All instructions that operate on an FPR are redefined to operate on doubleword element 0 of the corresponding VSR. The contents of doubleword element 1 of the VSR corresponding to a source FPR or FPR pair for these instructions are ignored and the contents of doubleword element 1 of the VSR corresponding to the target FPR or FPR pair for these instructions are set to 0.
Figure 107. Floating-Point Registers as part of VSRs
7.2.1.2 Vector Registers

Chapter 6, Vector Facility, provides 32 128-bit VRs. When VSX is implemented, the 32 VRs are mapped to VSRs 32-63. For example, VR[0] is located in VSR[32], VR[1] is located in VSR[33], and so forth. All instructions that operate on a VR are redefined to operate on the corresponding VSR.

![Figure 108. Vector Registers as part of VSRs](image-url)
7.2.1.3 VSX Accumulators

Eight 512-bit Accumulators (ACC) are provided. Each ACC contains four 128-bit rows.

\[
\begin{align*}
\text{ACC}[i][0] &= \text{ACC}[i].\text{bit}[0:127] \\
\text{ACC}[i][1] &= \text{ACC}[i].\text{bit}[128:255] \\
\text{ACC}[i][2] &= \text{ACC}[i].\text{bit}[256:383] \\
\text{ACC}[i][3] &= \text{ACC}[i].\text{bit}[384:511] \\
\end{align*}
\]

Each ACC is associated with four VSRs in the following manner.

\[
\begin{align*}
\text{ACC}[0][0] &\leftrightarrow \text{VSR}[0] \\
\text{ACC}[0][1] &\leftrightarrow \text{VSR}[1] \\
\text{ACC}[0][2] &\leftrightarrow \text{VSR}[2] \\
\text{ACC}[0][3] &\leftrightarrow \text{VSR}[3] \\
\text{ACC}[1][0] &\leftrightarrow \text{VSR}[4] \\
\text{ACC}[1][1] &\leftrightarrow \text{VSR}[5] \\
\text{ACC}[1][2] &\leftrightarrow \text{VSR}[6] \\
\text{ACC}[1][3] &\leftrightarrow \text{VSR}[7] \\
&\vdots \\
\text{ACC}[7][0] &\leftrightarrow \text{VSR}[28] \\
\text{ACC}[7][1] &\leftrightarrow \text{VSR}[29] \\
\text{ACC}[7][2] &\leftrightarrow \text{VSR}[30] \\
\text{ACC}[7][3] &\leftrightarrow \text{VSR}[31] \\
\end{align*}
\]

While the ACCs are treated as separate registers from the VSRs, ACC[i] may use its associated VSRs 4×i to 4×i+3 as scratch space. That is, when ACC[i] contains defined data, the contents of VSRs 4×i to 4×i+3 are undefined until either a VSX Move From ACC instruction is used to copy the contents of ACC[i] to VSRs 4×i to 4×i+3 or some other instruction directly writes to one of these VSRs.

Any instruction that targets any VSR(s) associated with an ACC causes any subsequent use of that ACC as a source operand to be undefined, but causes the contents of all VSRs associated with the ACC to be undefined.

**Programming Note**

Application software must strictly adhere to the programming model described in this section to guarantee compatibility with future versions of the architecture.

For this version of the architecture, the hardware implementation provides the effect of ACC[i] and VSRs 4×i to 4×i+3 logically containing the same data. Being subject to change in future versions of this architecture, application software must not rely on this behavior. However, system software that handles context save/restore operations need only save and restore data from and to the VSRs (that is, the most current data between the VSRs and associated ACCs will be provided by the hardware implementation). The Accumulators introduce no new logical state at this time. However, future versions of the architecture may define new architectural state or re-define the backing state of the ACC registers. In turn, this may require changes to the system software to support programs written according to this version of the architecture.

The following instructions can be used to copy the contents of an ACC into its associated VSRs.

**VSX Move From Accumulator (xxmfacc)**

The contents of the source ACC are copied into the VSRs associated with the target ACC.

The following instructions can be used to initialize the contents of an ACC.

**VSX Move To Accumulator (xxmtacc)**

The contents of the VSRs associated with the target ACC are copied into the target ACC.

**VSX Set ACC to Zero (xxsetaccz)**

The target ACC is set to 0.

**[Prefixed Masked] VSX Vector 4-bit Signed Integer GER (rank-8) ([pm]xvi4ger8)**

The sum of the eight outer products of the 4-bit signed integer values in the two vector source operands are placed into the target ACC.

**[Prefixed Masked] VSX Vector 8-bit Signed/Unsigned Integer GER (rank-4) ([pm]xvi8ger4)**

The sum of the four outer products of the 8-bit signed and unsigned integer values in the two vector source operands are placed into the target ACC.
[Prefixed Masked] VSX Vector 16-bit Signed Integer GER (rank-2) ([pm]xvi16ger2s)
The sum of the two outer products of the 16-bit signed integer values in the two vector source operands are placed into the target ACC.

[Prefixed Masked] VSX Vector 16-bit Floating-Point GER (rank-2) ([pm]xvf16ger2)
The sum of the two outer products of the 16-bit floating-point values in the two vector source operands are placed into the target ACC.

[Prefixed Masked] VSX Vector bfloat16 GER (rank-2) ([pm]xvb16ger2)
The sum of the two outer products of the bfloat16 values in the two vector source operands are placed into the target ACC.

[Prefixed Masked] VSX Vector 32-bit Floating-Point GER (rank-1) ([pm]xvf32ger)
The outer product of the 32-bit floating-point values in the two vector source operands is placed into the target ACC.

[Prefixed Masked] VSX Vector 64-bit Floating-Point GER (rank-1) ([pm]xvf64ger)
The outer product of the 64-bit floating-point values in the two vector source operands is placed into the target ACC.
7.2.2 Floating-Point Status and Control Register

The Floating-Point Status and Control Register (FPSCR) controls the handling of floating-point exceptions and records status resulting from the floating-point operations. Bits 0:19 and 32:55 are status bits. Bits 56:63 are control bits.

The exception status bits in the FPSCR (bits 35:44, 53:55) are sticky; that is, once set to 1 they remain set to 1 until they are set to 0 by an \texttt{mcrfs}, \texttt{mtfsfi}, \texttt{mtfsf}, or \texttt{mtfsb0} instruction. The exception summary bits in the FPSCR (FX, FEX, and VX, which are bits 32:34) are not considered to be “exception status bits”, and only FX is sticky.

FX and VX are simply the ORs of other FPSCR bits. Therefore these two bits are not listed among the FPSCR bits affected by the various instructions.

The bit definitions for the FPSCR are as follows.

<table>
<thead>
<tr>
<th>Bit(s)</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0:28</td>
<td>Decimal Floating-Point Rounding Control (DRN)</td>
</tr>
<tr>
<td></td>
<td>This field is not used by VSX instructions.</td>
</tr>
<tr>
<td>32</td>
<td>Floating-Point Exception Summary (FX)</td>
</tr>
<tr>
<td></td>
<td>Every floating-point instruction, except \texttt{mtfsfi} and \texttt{mtfsf}, implicitly sets FX to 1 if that instruction causes any of the floating-point exception bits in the FPSCR to change from 0 to 1. \texttt{mcrfs}, \texttt{mtfsfi}, \texttt{mtfsf}, \texttt{mtfsb0}, and \texttt{mtfsb1} can alter FX explicitly.</td>
</tr>
</tbody>
</table>

\begin{center}
\textbf{Programming Note}

FX is defined not to be altered implicitly by \texttt{mtfsfi} and \texttt{mtfsf} because permitting these instructions to alter FX implicitly can cause a paradox. An example is an \texttt{mtfsfi} or \texttt{mtfsf} instruction that supplies 0 for FX and 1 for OX, and is executed when OX=0. See also the Programming Notes with the definition of these two instructions.
\end{center}

Bit(s) Definition

47:51 Floating-Point Result Flags (FPRF)
VSX Scalar Floating-Point Arithmetic, VSX Scalar DP-SP Conversion, VSX Scalar Convert Integer to Double-Precision, and VSX Scalar Round to Double-Precision Integer class instructions set this field based on the result placed into the target register and on the target precision, except that if any portion of the result is undefined then the value placed into FPRF is undefined.

For VSX Scalar Convert Double-Precision to Integer class instructions, the value placed into FPRF is undefined.

Additional details are as follows.

Table 2. Floating-Point Result Flags

47 Floating-Point Result Class Descriptor (C)
VSX Scalar Floating-Point Arithmetic, VSX Scalar DP-SP Conversion, VSX Scalar Convert Integer to Double-Precision, and VSX Scalar Round to Double-Precision Integer class instructions set this bit with the FPCC bits, to indicate the class of the result as shown in Table 2, “Floating-Point Result Flags,” on page 505. Note that in this case the high-order three bits of the FPCC retain their relational significance indicating that the value is less than, greater than, or equal to zero.

48 Floating-Point Less Than or Negative (FL)

49 Floating-Point Greater Than or Positive (FG)

50 Floating-Point Equal or Zero (FE)

51 Floating-Point Unordered or NaN (FU)

52 Reserved

53 Floating-Point Invalid Operation Exception (Software-Defined Condition) (VXSOFT)
This bit can be altered only by mcrfs, mtfsfi, mtfsf, mtfsb0, or mtfsb1. See Section 7.4.1, “Floating-Point Invalid Operation Exception” on page 527.

Programming Note
VXSOFT can be used by software to indicate the occurrence of an arbitrary, software-defined, condition that is to be treated as an Invalid Operation exception. For example, the bit could be set by a program that computes a base 10 logarithm if the supplied input is negative.

54 Floating-Point Invalid Operation Exception (Invalid Square Root) (VXSQRT)
This bit is set to 1 when a VSX Scalar Floating-Point Arithmetic or VSX Vector Floating-Point Arithmetic class instruction causes an Invalid Square Root type Invalid Operation exception. See Section 7.4.1, “Floating-Point Invalid Operation Exception” on page 527.

This bit can be set to 0 or 1 by a Move To FPSCR class instruction.

</tr>
</tbody>
</table>

**Programming Note**

When the processor is in floating-point non-IEEE mode, the results of floating-point operations is permitted to be approximate, and performance for these operations might be better, more predictable, or less data-dependent than when the processor is not in non-IEEE mode. For example, in non-IEEE mode an implementation is permitted to return 0 instead of a denormalized number and return a large number instead of an infinity.
Floating-Point Rounding Control \( (R\|n) \)

This field is used by VSX Scalar Floating-Point and VSX Vector Floating-Point class instructions that round their result and the rounding mode is not implied by the opcode.

This bit can be explicitly set or reset by a new Move To FPSCR class instruction.

See Section 7.3.2.6, “Rounding” on page 518.

7.3 VSX Operations

7.3.1 VSX Floating-Point Arithmetic Overview

This section describes the floating-point arithmetic and exception model supported by Vector-Scalar Extension. Except for extensions to support 32-bit single-precision floating-point vector operations, the models are identical to that described in Chapter 4. Floating-Point Facility.

The processor (augmented by appropriate software support, where required) implements a floating-point system compliant with the ANSI/IEEE Standard 754-1985, *IEEE Standard for Binary Floating-Point Arithmetic* (hereafter referred to as the IEEE standard). That standard defines certain required "operations" (addition, subtraction, and so on). Herein, the term, floating-point operation, is used to refer to one of these required operations and to additional operations defined (e.g., those performed by Multiply-Add or Reciprocal Estimate instructions). A Non-IEEE mode is also provided. This mode, which is permitted to produce results not in strict compliance with the IEEE standard, allows shorter latency.

Instructions are provided to perform arithmetic, rounding, conversion, comparison, and other operations in VSRs; to move floating-point data between storage and these registers.

These instructions are divided into two categories.

- computational instructions

  The computational instructions are those that perform addition, subtraction, multiplication, division, extracting the square root, rounding, conversion, comparison, and combinations of these operations. These instructions provide the floating-point operations. There are two forms of computational instructions, scalar, which perform a single floating-point operation, and vector, which perform either two double-precision floating-point operations or four single-precision operations. Computational instructions place status information into the Floating-Point Status and Control Register. They are the instructions described in Sections 7.6.1.3 through 7.6.1.8.2.

- noncomputational instructions

  The noncomputational instructions are those that perform loads and stores, move the contents of a VSR to another floating-point register possibly altering the sign, and select the value from one of two VSRs based on the value in a third VSR. The operations performed by these instructions are not considered floating-point operations. These instructions do not alter the Floating-Point Status and Control Register. They are the instructions listed in Sections 7.6.1.1, 7.6.1.2.1, and 7.6.1.3 through .

A floating-point number consists of a signed exponent and a signed significand. The quantity expressed by this number is the product of the significand and the number \(2^{\text{exponent}}\). Encodings are provided in the data format to represent finite numeric values, \(\pm\infty\), and values that are “Not a Number” (NaN). Operations involving infinities produce results obeying traditional mathematical conventions. NaNs have no mathematical interpretation. Their encoding permits a variable diagnostic information field. NaNs might be used to indicate such things as uninitialized variables and can be produced by certain invalid operations.

There is one class of exceptional events that occur during instruction execution that is unique to Vector-Scalar Extension and Floating-Point: the Floating-Point Exception. Floating-point exceptions are signaled with bits set in the FPSCR. They can cause the system floating-point enabled exception error handler to be invoked, precisely or imprecisely, if the proper control bits are set.

**Floating-Point Exceptions**

The following floating-point exceptions are detected by the processor:

- Invalid Operation exception (VX)
  - SNaN (VXSNaN)
  - Infinity- Infinity (VXI1S1)
  - Infinity+Infinity (VXI1D1)
  - Zero+Zero (VXZDZ)
  - Infinity×Zero (VXI1M2)
  - Invalid Compare (VXXC)
  - Software-Defined Condition (VXSOFT)
  - Invalid Square Root (VXSQRT)
  - Invalid Integer Convert (VXXVI)

- Zero Divide exception (ZX)
- Overflow exception (OX)
- Underflow exception (UX)
- Inexact exception (XX)

Each floating-point exception, and each category of Invalid Operation exception, has an exception bit in the FPSCR. In addition, each floating-point exception has a corresponding enable bit in the FPSCR. See Section 7.2.2, “Floating-Point Status and Control Register” on page 503 for a description of these exception and enable bits, and Section 7.3.3, “VSX Floating-Point Execution Models” on page 521 for a detailed discussion of floating-point exceptions, including the effects of the enable bits.
7.3.2 VSX Floating-Point Data

7.3.2.1 Data Format

This architecture defines the representation of a floating-point value in five different binary fixed-length formats, 16-bit half-precision format, 16-bit bfloat16 format, 32-bit single-precision format, 64-bit double-precision format, and 128-bit quad-precision format. The half-precision format is used for half-precision floating-point data in storage and registers. The bfloat16 format is used for bfloat16 floating-point data in storage and registers. The single-precision format is used for single-precision floating-point data in storage and registers. The double-precision format is used for double-precision floating-point data in storage and registers. The quad-precision format is used for quad-precision floating-point data in storage and registers.

The lengths of the exponent and the fraction fields differ between these five formats. The structure of the half-precision, bfloat16, single-precision, double-precision, and quad-precision formats is shown in Figure 109, Figure 110, Figure 111, Figure 112, and Figure 113, respectively.

Values in floating-point format are composed of three fields:

- **S** sign bit
- **EXP** exponent+bias
- **FRACTION** fraction

Representation of numeric values in the floating-point formats consists of a sign bit (S), a biased exponent (EXP), and the fraction portion (FRACTION) of the significand. The significand consists of a leading implied bit concatenated on the right with the FRACTION. This leading implied bit is 1 for normalized numbers and 0 for denormalized (subnormal) numbers or zero and is located in the unit bit position (that is, the first bit to the left of the binary point). Values representable within the three floating-point formats can be specified by the parameters listed in Table 3.

Table 3. Binary floating-point fields
7.3.2.2 Value Representation

This architecture defines numeric and nonnumeric values representable within each of the three supported formats. The numeric values are approximations to the real numbers and include the normalized numbers, denormalized numbers, and zero values. The nonnumeric values representable are the infinities and the Not a Numbers (NaNs). The infinities are adjoined to the real numbers, but are not numbers themselves, and the standard rules of arithmetic do not hold when they are used in an operation. They are related to the real numbers by order alone. It is possible however to define restricted operations among numbers and infinities as defined below. The relative location on the real number line for each of the defined entities is shown in Figure 114.

Figure 114. Approximation to real numbers

<table>
<thead>
<tr>
<th>-INF</th>
<th>-NOR</th>
<th>-DEN</th>
<th>0+0</th>
<th>+DEN</th>
<th>+NOR</th>
<th>+INF</th>
</tr>
</thead>
</table>

The NaNs are not related to the numeric values or infinities by order or value but are encodings used to convey diagnostic information such as the representation of uninitialized variables.

The following is a description of the different floating-point values defined in the architecture:

Binary floating-point numbers

Machine representable values used as approximations to real numbers. Three categories of numbers are supported: normalized numbers, denormalized numbers, and zero values.

Normalized numbers (±NOR)

These are values that have a biased exponent value in the range:

- 1 to 30 in half-precision format
- 1 to 254 in bfloat16 format
- 1 to 254 in single-precision format
- 1 to 2046 in double-precision format
- 1 to 32766 in quad-precision format

They are values in which the implied unit bit is 1.

Normalized numbers are interpreted as follows:

\[
\text{NOR} = (-1)^s \times 2^{E} \times (1.fraction)
\]

where \( s \) is the sign, \( E \) is the unbiased exponent, and \( 1.fraction \) is the significand, which is composed of a leading unit bit (implied bit) and a fraction part.

Zero values (±0)

These are values that have a biased exponent value of zero and a fraction value of zero. Zeros can have a positive or negative sign. The sign of zero is ignored by comparison operations (that is, comparison regards +0 as equal to -0).

Denormalized numbers (±DEN)

These are values that have a biased exponent value of zero and a nonzero fraction value. They are nonzero numbers smaller in magnitude than the representable normalized numbers. They are values in which the implied unit bit is 0.

Denormalized numbers are interpreted as follows:

\[
\text{DEN} = (-1)^s \times 2^{E_{\text{min}}} \times 0.fraction
\]

where \( E_{\text{min}} \) is the minimum representable exponent value.

- 14 for half-precision
- 126 for bfloat16
- 126 for single-precision
- 1022 for double-precision
- 16382 for quad-precision.

Infinities (±INF)

These are values that have the maximum biased exponent value:

- 31 in half-precision format
- 255 in bfloat16 format
- 255 in single-precision format
- 2047 in double-precision format
- 32767 in quad-precision format

and a zero fraction value. They are used to approximate values greater in magnitude than the maximum normalized value.

Infinity arithmetic is defined as the limiting case of real arithmetic, with restricted operations defined among numbers and infinities. Infinities and the real numbers can be related by ordering in the affine sense:

\[-\text{Infinity} < \text{every finite number} < +\text{Infinity}\]

Arithmetic on infinities is always exact and does not signal any exception, except when an exception occurs due to the invalid operations as described in Section 7.4.1, "Floating-Point Invalid Operation Exception" on page 527.

For comparison operations, +Infinity compares equal to +Infinity and -Infinity compares equal to -Infinity.
Not a Numbers (NaNs)

These are values that have the maximum biased exponent value and a nonzero fraction value. The sign bit is ignored (that is, NaNs are neither positive nor negative). If the high-order bit of the fraction field is 0, the NaN is a Signaling NaN; otherwise it is a Quiet NaN.

Signaling NaNs are used to signal exceptions when they appear as operands of computational instructions.

Quiet NaNs are used to represent the results of certain invalid operations, such as invalid arithmetic operations on infinities or on NaNs, when Invalid Operation exception is disabled (VE=0). Quiet NaNs propagate through all floating-point operations except ordered comparison and conversion to integer. Quiet NaNs do not signal exceptions, except for ordered comparison and conversion to integer operations. Specific encodings in QNaNs can thus be preserved through a sequence of floating-point operations, and used to convey diagnostic information to help identify results from invalid operations.

Assume the following generic arithmetic templates.

\[
\begin{align*}
f(src1,src3,src2) & \quad \text{ex: } \text{result} = (src1 \times src3) - src2 \\
f(src1,src2) & \quad \text{ex: } \text{result} = src1 \times src2 \\
f(src1) & \quad \text{ex: } \text{result} = f(src1)
\end{align*}
\]

When a QNaN is the result of a floating-point operation because one of the operands is a NaN or because a QNaN was generated due to a trap-disabled Invalid Operation exception, the following rule is applied to determine the NaN with the high-order fraction bit set to 1 that is to be stored as the result.

\[
\begin{align*}
\text{if src1 is a NaN} & \quad \text{then result = Quiet(src1)} \\
\text{else if src2 is a NaN (if there is a src2)} & \quad \text{then result = Quiet(src2)} \\
\text{else if src3 is a NaN (if there is a src3)} & \quad \text{then result = Quiet(src3)} \\
\text{else if disabled invalid operation exception} & \quad \text{then result = generated QNaN}
\end{align*}
\]

where \(\text{Quiet}(x)\) means \(x\) if \(x\) is a QNaN and \(x\) converted to a QNaN if \(x\) is an SNaN. Any instruction that generates a QNaN as the result of a disabled Invalid Operation exception generates the value,

- \(0x7E00\) for half-precision results,
- \(0x7FC0\) for bfloat16 results,
- \(0x7FC0_{0000}\) for single-precision results,
- \(0x7FF8_{0000_0000_0000}\) for double-precision results,
- \(0x7FFF_{8000_0000_0000_0000_0000_0000_0000}\) for quad-precision results.

Note that the M-form multiply-add-type instructions use the \(B\) source operand to specify \(src3\) and the \(T\) target operand to specify \(src2\), whereas A-form multiply-add-type instructions use the \(B\) source operand to specify \(src2\) and the \(T\) target operand to specify \(src3\).

A double-precision NaN is considered to be representable in single-precision format if and only if the low-order 29 bits of the double-precision NaN’s fraction are zero.

7.3.2.3 Sign of Result

The following rules govern the sign of the result of an arithmetic, rounding, or conversion operation, when the operation does not yield an exception. They apply even when the operands or results are zeros or infinities.

- The sign of the result of an add operation is the sign of the operand having the larger absolute value. If both operands have the same signs, the sign of the result of an add operation is the same as the sign of the operands. The sign of the result of the subtract operation \(x-y\) is the same as the sign of the result of the add operation \(x+(-y)\).
When the sum of two operands with opposite sign, or the difference of two operands with the same signs, is exactly zero, the sign of the result is positive in all rounding modes except Round toward -Infinity, in which mode the sign is negative.

- The sign of the result of a multiply or divide operation is the Exclusive OR of the signs of the operands.

- The sign of the result of a Square Root or Reciprocal Square Root Estimate operation is always positive, except that the square root of -0 is -0 and the reciprocal square root of -0 is -Infinity.

- The sign of the result of a Convert From Integer or Round to Floating-Point Integer operation is the sign of the operand being converted.

For the Multiply-Add instructions, the rules given above are applied first to the multiply operation and then to the add or subtract operation (one of the inputs to the add or subtract operation is the result of the multiply operation).

### 7.3.2.4 Normalization and Denormalization

The intermediate result of an arithmetic instruction can require normalization and/or denormalization as described below. Normalization and denormalization do not affect the sign of the result.

When an arithmetic or rounding instruction produces an intermediate result which carries out of the significand, or in which the significand is nonzero but has a leading zero bit, it is not a normalized number and must be normalized before it is stored. For the carry-out case, the significand is shifted right one bit, with a one shifted into the leading significand bit, and the exponent is incremented by one. For the leading-zero case, the significand is shifted left while decrementing its exponent by one for each bit shifted, until the leading significand bit becomes one. The Guard bit and the Round bit (see Section 7.3.3.1, “VSX Execution Model for IEEE Operations” on page 521) participate in the shift with zeros shifted into the Round bit. The exponent is regarded as if its range were unlimited.

After normalization, or if normalization was not required, the intermediate result can have a nonzero significand and an exponent value that is less than the minimum value that can be represented in the format specified for the result. In this case, the intermediate result is said to be “Tiny” and the stored result is determined by the rules described in Section 7.4.4, “Floating-Point Underflow Exception” on page 548. These rules can require denormalization.

A number is denormalized by shifting its significand right while incrementing its exponent by 1 for each bit shifted, until the exponent is equal to the format's minimum value. If any significant bits are lost in this shifting process, “Loss of Accuracy” has occurred (See Section 7.4.4, “Floating-Point Underflow Exception” on page 548) and Underflow exception is signaled.

### Engineering Note

When denormalized numbers are operands of multiply, divide, and square root operations, some implementations might prenormalize the operands internally before performing the operations.

### 7.3.2.5 Data Handling and Precision

Scalar double-precision floating-point data is represented in double-precision format in VSRs and storage.

Vector double-precision floating-point data is represented in double-precision format in VSRs and storage.

Scalar single-precision floating-point data is represented in double-precision format in VSRs and in single-precision format in storage.

Vector single-precision floating-point data is represented in single-precision format in VSRs and storage.

Double-precision operands may be used as input for double-precision scalar arithmetic operations.

Double-precision operands may be used as input for single-precision scalar arithmetic operations when trapping on overflow and underflow exceptions is disabled.

Single-precision operands may be used as input for double-precision and single-precision scalar arithmetic operations.

Double-precision operands may be used as input for double-precision vector arithmetic operations.

Single-precision operands may be used as input for single-precision vector arithmetic operations.

Instructions are also provided for manipulations which do not require double-precision or single-precision. In addition, instructions are provided to access an integer representation in GPRs.
Half-Precision Operands

Instructions are provided to convert between half-precision and single-precision formats for vector data in VSRs and between half-precision and double-precision formats for scalar data. Note that scalar double-precision format is identical to scalar single-precision format.

An instruction is provided to explicitly convert half-precision format operands in a VSR to single-precision format. Scalar single-precision floating-point is enabled with six types of instruction.

1. **VSX Scalar Convert Half-Precision to Double-Precision format XX2-form**

   The half-precision floating-point value in the rightmost halfword in doubleword element 0 of the source VSR is placed into the doubleword element 0 of the target VSR in double-precision format.

2. **VSX Scalar Convert with round Double-Precision to Half-Precision format XX2-form**

   The double-precision value in doubleword element 0 of the source VSR is rounded to to half-precision, checking the exponent for half-precision range and handling any exceptions according to respective enable bits, and places the result into the rightmost halfword of doubleword element 0 of the target VSR in half-precision format.

   Source operand values greater in magnitude than $2^{39}$ when Overflow is enabled ($OE=1$) produce undefined results because the value cannot be scaled into the half-precision normalized range.

   Source operand values smaller in magnitude than $2^{-38}$ when Underflow is enabled ($UE=1$) produce undefined results because the value cannot be scaled into the half-precision normalized range.

3. **VSX Vector Convert bfloat16 to Single-Precision format XX2-form**

   The bfloat16 floating-point value in the rightmost halfword of each word element of the source VSR is placed into the corresponding word element of the target VSR in single-precision format.

4. **VSX Vector Convert with round Single-Precision to bfloat16 format XX2-form**

   The single-precision floating-point value in each word element $i$ of the source VSR is rounded to bfloat16 precision and placed into the rightmost halfword of the corresponding word element of the target VSR in bfloat16 format.

bfloat16 Operands

Instructions are provided to convert between bfloat16 and single-precision formats for vector data in VSRs.

An instruction is provided to explicitly convert bfloat16 format operands in a VSR to single-precision format.

1. **VSX Vector Convert bfloat16 to Single-Precision format XX2-form**

   The bfloat16 floating-point value in the rightmost halfword of each word element of the source VSR is placed into the corresponding word element of the target VSR in single-precision format.

2. **VSX Vector Convert with round Single-Precision to bfloat16 format XX2-form**

   The single-precision floating-point value in each word element $i$ of the source VSR is rounded to bfloat16 precision and placed into the rightmost halfword of the corresponding word element of the target VSR in bfloat16 format.

Single-Precision Operands

For single-precision scalar data, a conversion from single-precision format to double-precision format is performed when loading from storage into a VSR and a conversion from double-precision format to single-precision format is performed when storing from a VSR to storage. No floating-point exceptions are caused by these instructions.

Instructions are provided to convert between single-precision and double-precision formats for scalar and vector data in VSRs.

An instruction is provided to explicitly convert a double format operand in a VSR to single-precision. Scalar single-precision floating-point is enabled with six types of instructions.

1. **Load VSX Scalar Single-Precision**

   $[p]lxssp$ and $lxssp$ access a floating-point operand in single-precision format in storage, converts it to double-precision format, and loads it into a VSR. No floating-point exceptions are caused by these instructions.

2. **VSX Scalar Round to Single-Precision XX2-form**

   $xsrsp$ rounds a double-precision operand to single-precision, checking the exponent for single-precision range and handling any
exceptions according to respective enable bits, and places that operand into a VSR in double-precision format. For results produced by single-precision arithmetic instructions, single-precision loads, and other instances of \texttt{xrsps}, \texttt{xrsrp} does not alter the value. Values greater in magnitude than $2^{-319}$ when Overflow is enabled (\texttt{OE=1}) produce undefined results because the value cannot be scaled back into the normalized range. Values smaller in magnitude than $2^{-318}$ when Underflow is enabled (\texttt{UE=1}) produce undefined results because the value cannot be scaled back into the normalized range.

3. **VSX Scalar Convert Single-Precision to Double-Precision format**

**VSX Scalar Convert Single-Precision to Double-Precision format** \texttt{XX2-form (xscvspdp)} accesses a floating-point operand in single-precision format from word element \texttt{0} of the source VSR, converts it to double-precision format, and places it into doubleword element \texttt{0} of the target VSR.

**VSX Scalar Convert Single-Precision to Double-Precision format Non-signalling XX2-form (xscvspdpn)** accesses a floating-point operand in single-precision format from word element \texttt{0} of the source VSR, converts it to double-precision format, and places it into doubleword element \texttt{0} of the target VSR. \texttt{xscvspdpn} does not set any exception status (i.e., \texttt{VXSNAN}).

4. **VSX Scalar Convert Double-Precision to Single-Precision format** [Non-Signalling]

**VSX Scalar Convert with round Double-Precision to Single-Precision format** \texttt{XX2-form (xscvdpsp)} rounds the double-precision floating-point value in doubleword element \texttt{0} of the source VSR to single-precision, and places the result into word elements \texttt{0} and \texttt{1} of the target VSR in single-precision format. This function would be used to port scalar floating-point data to a format compatible for single-precision vector operations. Values greater in magnitude than $2^{-319}$ when Overflow is enabled (\texttt{OE=1}) produce undefined results because the value cannot be scaled back into the normalized range. Values smaller in magnitude than $2^{-318}$ when Underflow is enabled (\texttt{UE=1}) produce undefined results because the value cannot be scaled back into the normalized range.

**VSX Scalar Convert Scalar Single-Precision to Vector Single-Precision format Non-signalling**

\texttt{XX2-form (xscvdpsspn)} directly converts the single-precision floating-point value represented in double-precision format in doubleword element \texttt{0} of the source VSR to single-precision format, without rounding, and places the result into word elements \texttt{0} and \texttt{1} of the target VSR in single-precision format. \texttt{xscvdpsspn} does not set any exception status (i.e., \texttt{VXSNAN}).

5. **VSX Scalar Single-Precision Arithmetic**

This form of instruction takes operands from the VSRs in double format, performs the operation as if it produced an intermediate result having infinite precision and unbounded exponent range, and then coerces this intermediate result to fit in single-precision format. Status bits, in the FPSCR and optionally in the Condition Register, are set to reflect the single-precision result. The result is then placed into the target VSR in double-precision format. The result lies in the range supported by the single format.

If any input value is not representable in single-precision format and either \texttt{OE=1} or \texttt{UE=1}, the result placed into the target VSR and the setting of status bits in the FPSCR are undefined.

For \texttt{xrsrsp} or \texttt{xrsqrtesp}, if the input value is finite and has an unbiased exponent greater than $+127$, the input value is interpreted as an Infinity.

6. **Store VSX Scalar Single-Precision**

Store VSX Scalar Single-Precision DS-form (\texttt{stxssp}), Prefixed Store VSX Scalar Single-Precision 8LS:D-form (\texttt{pstxssp}), and Store VSX Scalar Single-Precision Indexed X-form (\texttt{stxsspx}) convert a single-precision value that is in double-precision format to single-precision format and stores that operand into storage. No floating-point exceptions are caused by these instructions. (The value being stored is effectively assumed to be the result of an instruction of one of the preceding five types.)

When the result of a Load VSX Scalar Single-Precision (\texttt{lxsspx}), a VSX Scalar Round to Single-Precision (\texttt{xrsrp}), or a VSX Scalar Single-Precision Arithmetic instruction is stored in a VSR, the low-order 29 bits of \texttt{FRACTION} are zero.

---

1. VSX Scalar Single-Precision Arithmetic instructions:
   \texttt{xssaddsp}, \texttt{xsvdivsp}, \texttt{xsmulp}, \texttt{xrsrp}, \texttt{xssubsp}, \texttt{xsmaddsp}, \texttt{xsmaddsp}, \texttt{xsmsubasp}, \texttt{xsmsubmsp}, \texttt{xsmnaddsp}, \texttt{xsmnaddsp}, \texttt{xsnmsubsp}, \texttt{xsmnmsubsp}
Integer-Valued Operands

Instructions are provided to round floating-point operands to integer values in floating-point format. To facilitate exchange of data between the floating-point and integer processing, instructions are provided to convert between floating-point double and single-precision format and integer word and doubleword format in a VSR. Computation on integer-valued operands can be performed using arithmetic instructions of the required precision. (The results might not be integer values.) The three groups of instructions provided specifically to support integer-valued operands are described below.

1. Rounding to a floating-point integer

   **VSX Scalar Round to Double-Precision Integer**: Instructions round a double-precision operand to an integer value in double-precision format. These instructions can also be used for single-precision operands represented in double-precision format.
VSX Vector Round to Double-Precision Integer\(^1\) instructions round each double-precision vector operand element to an integer value in double-precision format.

VSX Vector Round to Single-Precision Integer\(^2\) instructions round each single-precision vector operand element to an integer value in single-precision format.

Except for \texttt{xsrdpic}, \texttt{xvrdpic}, and \texttt{xvrspic}, rounding is performed using the rounding mode specified by the opcode. For \texttt{xsrdpic}, \texttt{xvrdpic}, and \texttt{xvrspic}, rounding is performed using the rounding mode specified by \texttt{Rn}.

VSX Round to Floating-Point Integer\(^3\) instructions can cause Invalid Operation (\texttt{VXSNAN}) exceptions.

\texttt{xsrdpic}, \texttt{xvrdpic}, and \texttt{xvrspic} can also cause Inexact exception.

See Sections 7.3.2.6 and 7.3.3.1 for more information about rounding.

2. Converting floating-point format to integer format

VSX Scalar Double-Precision to Integer Format Conversion\(^4\) instructions convert a double-precision operand to 32-bit or 64-bit signed or unsigned integer format. These instructions can also be used for single-precision operands represented in double-precision format.

VSX Vector Double-Precision to Integer Format Conversion\(^5\) instructions convert either double-precision or single-precision vector operand elements to 32-bit or 64-bit signed or unsigned integer format.

VSX Vector Single-precision to Integer Doubleword Format Conversion\(^6\) instructions converts the single-precision value in each odd-numbered word element of the source vector operand to a 64-bit signed or unsigned integer format.

VSX Vector Single-precision to Integer Word Format Conversion\(^7\) instructions converts the single-precision value in each word element of the source vector operand to either a 32-bit signed or unsigned integer format.

Rounding is performed using Round Towards Zero rounding mode. These instructions can cause Invalid Operation (\texttt{VXSNAN}, \texttt{VXCVI}) and Inexact exceptions.

3. Converting integer format to floating-point format

VSX Scalar Integer Doubleword to Double-Precision Format Conversion\(^8\) instructions convert a 64-bit signed or unsigned integer to a double-precision floating-point value and returns the result in double-precision format.

VSX Scalar Integer Doubleword to Single-Precision Format Conversion\(^9\) instructions converts a 64-bit signed or unsigned integer to a single-precision floating-point value and returns the result in double-precision format.

VSX Vector Integer Doubleword to Double-Precision Format Conversion\(^10\) instructions converts the 64-bit signed or unsigned integer in each doubleword element in the source vector operand to double-precision floating-point format.

VSX Vector Integer Doubleword to Single-Precision Format Conversion\(^11\) instructions convert either double-precision or single-precision vector operand elements to 32-bit or 64-bit signed or unsigned integer format.

instructions convert the 64-bit signed or unsigned integer in each doubleword element in the source vector operand to single-precision floating-point format.

VSX Vector Integer Word to Single-Precision Format Conversion\(^1\) instructions convert the 32-bit signed or unsigned integer in each word element in the source vector operand to single-precision floating-point format.

Rounding is performed using the rounding mode specified in \(\text{RN}\). Because of the limitations of the source format, only an Inexact exception can be generated.

### 7.3.2.6 Rounding

The material in this section applies to operations that have numeric operands (that is, operands that are not infinities or NaNs). Rounding the intermediate result of such an operation can cause an Overflow exception, an Underflow exception, or an Inexact exception. The remainder of this section assumes that the operation causes no exceptions and that the result is numeric. See Section 7.3.2.2, “Value Representation” and Section 7.4, “VSX Floating-Point Exceptions” for the cases not covered here.

The floating-point arithmetic, and rounding and conversion instructions round their intermediate results. With the exception of the estimate instructions, these instructions produce an intermediate result that can be regarded as having unbounded precision and exponent range. All but two groups of these instructions normalize or denormalize the intermediate result prior to rounding and then place the final result into the target element of the target VSR in either double-precision, single-precision, or quad-precision format.

The scalar round to double-precision integer, vector round to double-precision integer, and convert double-precision to integer instructions with biased exponents ranging from 1022 through 1074 are prepared for rounding by repetitively shifting the significand right one position and incrementing the biased exponent until it reaches a value of 1075. (Intermediate results with biased exponents 1075 or larger are already integers, and with biased exponents 1021 or less round to zero.) After rounding, the final result for vector round to single-precision integer is normalized and put in double-precision format, and, for vector convert single-precision to integer is converted to a signed or unsigned integer.

\(\text{FR}\) and \(\text{FI}\) generally indicate the results of rounding. Each of the scalar instructions which rounds its intermediate result sets these bits. There are no vector instructions that modify \(\text{FR}\) and \(\text{FI}\). If the fraction is incremented during rounding, \(\text{FR}\) is set to 1, otherwise \(\text{FR}\) is set to 0. If the result is inexact, \(\text{FI}\) is set to 1, otherwise \(\text{FI}\) is set to zero. The scalar round to double-precision integer instructions are exceptions to this rule, setting \(\text{FR}\) and \(\text{FI}\) to 0. The scalar double-precision estimate instructions set \(\text{FR}\) and \(\text{FI}\) to undefined values. The remaining scalar floating-point instructions do not alter \(\text{FR}\) and \(\text{FI}\).

Four user-selectable rounding modes are provided through the Floating-Point Rounding Control field in the FPSCR. See Section 7.2.2, “Floating-Point Status and Control Register” on page 503. These are encoded as follows.

<table>
<thead>
<tr>
<th>(\text{RN})</th>
<th>Rounding Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Round to Nearest Even</td>
</tr>
<tr>
<td>01</td>
<td>Round towards Zero</td>
</tr>
<tr>
<td>10</td>
<td>Round towards +Infinity</td>
</tr>
<tr>
<td>11</td>
<td>Round towards -Infinity</td>
</tr>
</tbody>
</table>

A fifth rounding mode is provided in the round to floating-point integer instructions (Section 7.6.1.8.2 on page 572), Round to Nearest Away.

A sixth rounding mode is provided in the quad-precision floating-point instructions, Round to Odd.

---

1. VSX Vector Integer Word to Single-Precision Format Conversion instructions: 
\[\text{xscvsxwsp, xscvuxwsp}\]
Let \( Z \) be the intermediate arithmetic result or the operand of a convert operation. If \( Z \) can be represented exactly in the target format, the result in all rounding modes is \( Z \) as represented in the target format. If \( Z \) cannot be represented exactly in the target format, let \( Z_1 \) and \( Z_2 \) bound \( Z \) as the next larger and next smaller numbers representable in the target format. Then \( Z_1 \) or \( Z_2 \) can be used to approximate the result in the target format.

Figure 115 shows the relation of \( Z \), \( Z_1 \), and \( Z_2 \) in this case. The following rules specify the rounding in the four modes.

See Section 7.3.3.1, “VSX Execution Model for IEEE Operations” on page 521 for a detailed explanation of rounding.

Figure 115 also summarizes the rounding actions for floating-point intermediate result for all supported rounding modes.

Programming Note

Round to Odd rounding mode is useful when the results of a Quad-Precision Arithmetic instruction are required to be rounded to a shorter precision while avoiding a double rounding error. In this case, the rounding mode of the Quad-Precision Arithmetic instruction is overridden as Round To Odd by setting the \( RO \) bit in the instruction encoding to 1, then the result of that Quad-Precision Arithmetic instruction can be rounded to the desired shorter precision using the rounding mode specified in \( RN \) by following with a VSX Scalar Round Quad-Precision to Double-Extended-Precision for 15-bit exponent range and 64-bit significand precision, VSX Scalar Round Quad-Precision to Double-Precision for 11-bit exponent range and 53-bit significand precision, or VSX Scalar Round Quad-Precision to Single-Precision for 8-bit exponent range and 24-bit significand precision. For example,

\[
\begin{align*}
&\text{asaddpo } Tx, A, B ; \text{ use Round to Odd override } (RO=1) \\
&\text{asrgqep } Tdxp, Tx ; \text{ final QP result rounded to DXP}
\end{align*}
\]

To return a quad-precision result rounded to double-precision requires a 3-instruction sequence,

\[
\begin{align*}
&\text{asaddpo } Tx, A, B ; \text{ use Round to Odd override } (RO=1) \\
&\text{ascvqdp } Temp, Tx ; \text{ QP result rounded & converted to DP} \\
&\text{ascdqgp } Tdp, Temp ; \text{ final QP result rounded to DP}
\end{align*}
\]

To return a quad-precision result rounded to single-precision requires a 4-instruction sequence,

\[
\begin{align*}
&\text{asaddpo } Tx, A, B ; \text{ use Round to Odd override } (RO=1) \\
&\text{ascvqdp } Temp, Tx ; \text{ QP result rounded to DP using Round to Odd & converted to DP format} \\
&\text{asrsr } Temp, Temp ; \text{ DP result is rounded to SP} \\
&\text{ascvdpq } Tsp, Temp ; \text{ final QP result rounded to SP}
\end{align*}
\]
Round to Nearest Away
Choose Z if Z is representable in the target precision.

Otherwise, choose the value that is closer to Z (Z₁ or Z₂). In case of a tie, choose the one that is furthest away from 0.

Round to Nearest Even
Choose Z if Z is representable in the target precision.

Otherwise, choose the value that is closer to Z (Z₁ or Z₂). In case of a tie, choose the one that is even (least significant bit is 0).

Round to Odd
Choose Z if Z is representable in the target precision.

Otherwise, choose the value (Z₁ or Z₂) that is odd (least significant bit is 1).

Round toward Zero
Choose Z if Z is representable in the target precision.

Otherwise, choose the smaller in magnitude (Z₁ or Z₂).

Round toward +Infinity
Choose Z if Z is representable in the target precision.

Otherwise, choose Z₁.

Round toward -Infinity
Choose Z if Z is representable in the target precision.

Otherwise, choose Z₂.

Figure 115.Selection of Z₁ and Z₂
7.3.3 VSX Floating-Point Execution Models

All implementations of this architecture must provide the equivalent of the following execution models to ensure that identical results are obtained.

Special rules are provided in the definition of the computational instructions for the infinities, denormalized numbers and NaNs. The material in the remainder of this section applies to instructions that have numeric operands and a numeric result (that is, operands and result that are not infinities or NaNs), and that cause no exceptions. See Section 7.3.2.2 and Section 7.3.3 for the cases not covered here.

Although the double-precision format specifies an 11-bit exponent, exponent arithmetic makes use of two additional bits to avoid potential transient overflow and underflow conditions. One extra bit is required when denormalized double-precision numbers are prenormalized. The second bit is required to permit the computation of the adjusted exponent value in the following cases when the corresponding exception enable bit is 1:

- Underflow during multiplication using a denormalized operand.
- Overflow during division using a denormalized divisor.
- Undeflow during division using denormalized dividend and a large divisor.

The IEEE standard includes 32-bit and 64-bit arithmetic. The standard requires that single-precision arithmetic be provided for single-precision operands.

VSX defines both scalar and vector double-precision floating-point operations to operate only on double-precision operands. VSX also defines vector single-precision floating-point operations to operate only on single-precision operands.

7.3.3.1 VSX Execution Model for IEEE Operations

IEEE-conforming significand arithmetic is considered to be performed with a floating-point accumulator having the following format, where bits 0:p-1 comprise the significand of the intermediate result (where p is the length of the significand).

![Figure 116.IEEE quad-precision (binary128) floating-point execution model (p=113)](image)

![Figure 117.IEEE double-extended-precision floating-point execution model (p=64)](image)

![Figure 118.IEEE double-precision (binary64) floating-point execution model (p=53)](image)

![Figure 119.IEEE single-precision (binary32) floating-point execution model (p=24)](image)

The S bit is the sign bit.

The C bit is the carry bit, which captures the carry out of the significand.

The L bit is the leading unit bit of the significand, which receives the implicit bit from the operand.

For the quad-precision execution model, FRACTION is a 112-bit field that accepts the fraction of the operand.

For the double-extended-precision execution model, FRACTION is a 63-bit field that accepts the fraction of the operand. This model is used only by the VSX Scalar Round to Double-Extended-Precision instruction.

For the double-precision execution model, FRACTION is a 52-bit field that accepts the fraction of the operand.

For the single-precision execution model, FRACTION is a 23-bit field that accepts the fraction of the operand.

The Guard (G), Round (R), and Sticky (X) bits are extensions to the low-order bits of the accumulator to provide the effect of an unbounded significand. The G and R bits are required for postnormalization of the result. The G, R, and X bits are required during rounding to determine if the intermediate result is equally near the two nearest representable values. The X bit serves as an extension to the G and R bits by representing the logical OR of all bits that appear to the low-order side of the R bit, resulting from either shifting the accumulator right or to other generation of low-order result bits. The G and R bits participate in the left shifts with zeros being shifted into the R bit. Table 4 shows the significance of the G, R, and X bits with respect to the intermediate result (IR), the representable number.
next lower in magnitude (NL), and the representable number next higher in magnitude (NH).

</tr>
</tbody>
</table>

Table 5. Location of the Guard, Round, and Sticky bits in the IEEE execution model

The significand of the intermediate result is prepared for rounding by shifting its contents right, if required, until the least significant bit to be retained is in the low-order bit position of the fraction.

Six rounding modes are provided as described in Section 7.3.2.6, “Rounding” on page 518. The rules for rounding in each mode are as follows.

- **Round to Nearest Even**
  - If IR is exact, choose IR.
  - Otherwise, if IR is closer to NL, choose NL.
  - Otherwise, if IR is closer to NH, choose NH.
  - Otherwise, if IR is midway between NL and NH, choose whichever of NL and NH is even.

- **Round to Nearest Away**
  - If IR is exact, choose IR.
  - Otherwise, if G=0, choose NL.
  - Otherwise, if G=1, choose NH.

- **Round to Odd**
  - If IR is exact, choose IR.
  - Otherwise, choose NL, and if G=1, R=1, or X=1, the least-significant bit of the result is set to 1.

Four of the rounding modes are user-selectable through RN.

<table>
<thead>
<tr>
<th>RN</th>

<td>Round toward Zero</td>
</tr>
<tr>
<td>0b10</td>
<td>Round toward +Infinity</td>
</tr>
<tr>
<td>0b11</td>
<td>Round toward -Infinity</td>
</tr>
</tbody>
</table>

Round to Nearest Away is provided in the VSX Round to Floating-Point Integer instructions (Section 7.6.1.8.2 on page 572).

Round to Odd is provided in the VSX Quad-Precision Floating-Point Arithmetic instructions as an override to the rounding mode selected by RN with the rules for rounding as follows.

If G=1, R=1, or X=1, the result is inexact.

If rounding results in a carry into C, the significand is shifted right one position and the exponent is incremented by one. This yields an inexact result, and possibly also exponent overflow. Fraction bits are stored to the target VSR.

7.3.3.2 VSX Execution Model for Multiply-Add Type Instructions

This architecture provides a special form of instruction that performs up to three operations in one instruction (a multiplication, an addition, and a negation). With this added capability comes the special ability to produce a more exact intermediate result as input to the rounder. 32-bit arithmetic is similar, except that the FRACTION field is smaller.

Multiply-add significand arithmetic is considered to be performed with a floating-point accumulator having the
following format, where bits 0:106 comprise the significand of the intermediate result.

<table>
<thead>
<tr>
<th>S</th>
<th>C</th>
<th>L</th>
<th>FRACTION</th>
<th>X'</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>106</td>
</tr>
</tbody>
</table>

**Figure 120. Multiply-add 64-bit execution model**

The first part of the operation is a multiplication. The multiplication has two 53-bit significands as inputs, which are assumed to be prenormalized, and produces a result conforming to the above model. If there is a carry out of the significand (into the C bit), the significand is shifted right one position, shifting the L bit (leading unit bit) into the most significant bit of the FRACTION and shifting the C bit (carry out) into the L bit. All 106 bits (L bit, the FRACTION) of the product take part in the add operation. If the exponents of the two inputs to the adder are not equal, the significand of the operand with the smaller exponent is aligned (shifted) to the right by an amount that is added to that exponent to make it equal to the other input's exponent. Zeros are shifted into the left of the significand as it is aligned and bits shifted out of bit 105 of the significand are ORed into the X' bit. The add operation also produces a result conforming to the above model with the X' bit taking part in the add operation.

The result of the addition is then normalized, with all bits of the addition result, except the X' bit, participating in the shift. The normalized result serves as the intermediate result that is input to the rounder.

For rounding, the conceptual Guard, Round, and Sticky bits are defined in terms of accumulator bits. Figure 6 shows the positions of the Guard, Round, and Sticky bits for double-precision and single-precision floating-point numbers in the multiply-add execution model.

<table>
<thead>
<tr>
<th>Format</th>
<th>Guard</th>
<th>Round</th>
<th>Sticky</th>
</tr>
</thead>
<tbody>
<tr>
<td>Double</td>
<td>53</td>
<td>54</td>
<td>OR of 55:105, X'</td>
</tr>
<tr>
<td>Single</td>
<td>24</td>
<td>25</td>
<td>OR of 26:105, X'</td>
</tr>
</tbody>
</table>

**Table 6. Location of the Guard, Round, and Sticky bits in the multiply-add execution model**

The rules for rounding the intermediate result are the same as those given in Section 7.3.3.1.

If the instruction is a negative multiply-add or negative multiply-subtract type instruction, the final result is negated.
### 7.4 VSX Floating-Point Exceptions

This architecture defines the following floating-point exceptions under the IEEE-754 exception model:

- Invalid Operation exception

  - SNaN
  - Infinity
  - Infinity×Infinity
  - Zero
  - Infinity×Zero
  - Invalid Compare
  - Software-Defined Condition
  - Invalid Square Root
  - Invalid Integer Convert

- Zero Divide exception
- Overflow exception
- Underflow exception
- Inexact exception

These exceptions, other than Invalid Operation exception resulting from a Software-Defined Condition, can occur during execution of computational instructions. An Invalid Operation exception resulting from a Software-Defined Condition occurs when a Move To FPSCR instruction sets VXSOFT to 1.

Each floating-point exception, and each category of Invalid Operation exception, has an exception bit in the FPSCR. In addition, each floating-point exception has a corresponding enable bit in the FPSCR. The exception bit indicates the occurrence of the corresponding exception. If an exception occurs, the corresponding enable bit governs the result produced by the instruction and, in conjunction with the FE0 and FE1 bits (see page 525), whether and how the system floating-point enabled exception error handler is invoked. In general, the enabling specified by the enable bit is of invoking the system error handler, not of permitting the exception to occur. The occurrence of an exception depends only on the instruction and its inputs, not on the setting of any control bits. The only deviation from this general rule is that the occurrence of an Underflow exception depends on the setting of the enable bit.

A single instruction, other than `mtfsfi` or `mtfsf`, can set more than one exception bit only in the following cases:

- An Inexact exception can be set with an Overflow exception.
- An Inexact exception can be set with an Underflow exception.
- An Invalid Operation exception (SNaN) is set with an Invalid Operation exception (Infinity×0) for multiply-add class instructions for which the values being multiplied are infinity and zero and the value being added is an SNaN.
- An Invalid Operation exception (SNaN) can be set with an Invalid Operation exception (Invalid Compare) for ordered comparison instructions.
- An Invalid Operation exception (SNaN) can be set with an Invalid Operation exception (Invalid Integer Convert) for convert to integer instructions.

When an exception occurs, the writing of a result to the target register can be suppressed, or a result can be delivered, depending on the exception.

The writing of a result to the target register is suppressed for the certain kinds of exceptions, based on whether the instruction is a vector or a scalar instruction, so that there is no possibility that one of the operands is lost. For other kinds of exceptions and also depending on whether the instruction is a vector or a scalar instruction, a result is generated and written to the destination specified by the instruction causing the exception. The result can be a different value for the enabled and disabled conditions for some of these exceptions. Table 7 lists the types of exceptions and indicates whether a result is written to the target VSR or suppressed.

<table>

</tr>
</tbody>
</table>

Table 7. Exception Types Result Suppression
The subsequent sections define each of the floating-point exceptions and specify the action that is taken when they are detected.

The IEEE standard specifies the handling of exceptional conditions in terms of traps and trap handlers. In this architecture, an FPSCR exception enable bit of 1 causes generation of the result value specified in the IEEE standard for the trap enabled case; the expectation is that the exception is detected by software, which revises the result. An FPSCR exception enable bit of 0 causes generation of the default result value specified for the trap disabled (or no trap occurs or trap is not implemented) case. The expectation is that the exception is not detected by software, which uses the default result. The result to be delivered in each case for each exception is described in the following sections.

The IEEE default behavior when an exception occurs is to generate a default value and not to notify software. In this architecture, if the IEEE default behavior when an exception occurs is required for all exceptions, all FPSCR exception enable bits must be set to 0, and Ignore Exceptions Mode (see below) should be used. In this case, the system floating-point enabled exception error handler is not invoked, even if floating-point exceptions occur: software can inspect the FPSCR exception bits, if necessary, to determine whether exceptions have occurred.

In this architecture, if software is to be notified that a given kind of exception has occurred, the corresponding FPSCR exception enable bit must be set to 1, and a mode other than Ignore Exceptions Mode must be used. In this case, the system floating-point enabled exception error handler is invoked if an enabled floating-point exception occurs. The system floating-point enabled exception error handler is also invoked if a Move To FPSCR instruction causes an exception bit and the corresponding enable bit both to be 1. The Move To FPSCR instruction is considered to cause the enabled exception.

The FE0 and FE1 bits control whether and how the system floating-point enabled exception error handler is invoked if an enabled floating-point exception occurs. The location of these bits and the requirements for altering them are described in Book III. The system floating-point enabled exception error handler is never invoked because of a disabled floating-point exception. The effects of the four possible settings of these bits are as follows.

<table>
<thead>
<tr>
<th>FE0</th>
<th>FE1</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

</tr>
</tbody>
</table>

In all cases, the question of whether a floating-point result is stored, and what value is stored, is governed by the FPSCR exception enable bits, as described in subsequent sections, and is not affected by the value of the FE0 and FE1 bits.

In all cases in which the system floating-point enabled exception error handler is invoked, all instructions before the instruction at which the system floating-point enabled exception error handler is invoked have been completed, and no instruction after the instruction at which the system floating-point enabled exception error handler is invoked has begun execution. The instruction at which the system floating-point enabled exception error handler is invoked has completed if it is the excepting instruction.
and there is only one such instruction. Otherwise, it has not begun execution, or has been partially executed in some cases, as described in Book III.

**Programming Note**

In any of the three non-Precise modes, a *Floating-Point Status and Control Register* instruction can be used to force any exceptions, because of instructions initiated before the *Floating-Point Status and Control Register* instruction, to be recorded in the FPSCR. (This forcing is superfluous for Precise Mode.)

In both Imprecise modes, a *Floating-Point Status and Control Register* instruction can be used to force any invocations of the system floating-point enabled exception error handler that result from instructions initiated before the *Floating-Point Status and Control Register* instruction to occur. This forcing has no effect in Ignore Exceptions Mode, and is superfluous for Precise Mode.

The last sentence of the paragraph preceding this Programming Note can apply only in the Imprecise modes, or if the mode has just been changed from Ignore Exceptions Mode to some other mode. It always applies in the latter case.

To obtain the best performance across the widest range of implementations, the programmer should obey the following guidelines.

- If the IEEE default results are acceptable to the application, Ignore Exceptions Mode should be used with all FPSCR exception enable bits set to 0.

- If the IEEE default results are not acceptable to the application, Imprecise Nonrecoverable Mode should be used, or Imprecise Recoverable Mode if recoverability is needed, with FPSCR exception enable bits set to 1 for those exceptions for which the system floating-point enabled exception error handler is to be invoked.

- Ignore Exceptions Mode should not, in general, be used when any FPSCR exception enable bits are set to 1.

- Precise Mode can degrade performance in some implementations, perhaps substantially, and therefore should be used only for debugging and other specialized applications.
7.4.1 Floating-Point Invalid Operation Exception

7.4.1.1 Definition

An Invalid Operation exception occurs when an operand is invalid for the specified operation. The invalid operations are:

- **SNaN**
  Any floating-point operation on a Signaling NaN.

- **Infinity–Infinity**
  Magnitude subtraction of infinities.

- **Infinity+Infinity**
  Floating-point division of infinity by infinity.

- **Zero÷Zero**
  Floating-point division of zero by zero.

- **Infinity × Zero**
  Floating-point multiplication of infinity by zero.

- **Invalid Compare**
  Floating-point ordered comparison involving a NaN.

- **Invalid Square Root**
  Floating-point square root or reciprocal square root of a nonzero negative number.

- **Invalid Integer Convert**
  Floating-point-to-integer convert involving a number too large in magnitude to be represented in the target format, or involving an infinity or a NaN.

An Invalid Operation exception also occurs when an `mtfsfi`, `mtfsf`, or `mtfsb1` instruction is executed that sets `VXSOFT` to 1 (Software-Defined Condition).

The action to be taken depends on the setting of the Invalid Operation Exception Enable bit of the FPSCR.

7.4.1.2 Action for VE=1

When Invalid Operation exception is enabled (VE=1) and an Invalid Operation exception occurs, the following actions are taken:

For any of the following instructions,

- **VSX Scalar Floating-Point Arithmetic instructions**
- **VSX Scalar DP-SP Conversion instructions**
- **VSX Scalar Convert Floating-Point to Integer instructions**
- **VSX Scalar Round to Floating-Point Integer instructions**

do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

   - `VXSNAN` (if SNaN)
   - `VXISI` (if Infinity–Infinity)
   - `VXIDI` (if Infinity÷Infinity)
   - `VXZDZ` (if Zero÷Zero)
   - `VXIMZ` (if Infinity×Zero)
   - `VXSQRT` (if Invalid Square Root)
   - `VXCVI` (if Invalid Integer Convert)

2. Update of `VSR[XT]` is suppressed.

3. `FR` and `FI` are set to zero.

4. `FPRF` is unchanged.
For VSX Scalar Floating-Point Compare instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.

   - VXSNAN (if SNaN)
   - VXVC (if Invalid Compare)

2. FR, FI, and C are unchanged.

3. FPCC is set to reflect unordered.

For any of the following instructions,

- VSX Scalar Quad-Precision Arithmetic instructions:
  - xsaddqp[0], xsdivqp[0], xsmulpq[0], xssqrtqp[0], xssubqp[0]
  - xsmaddqp[0], xsmsubqp[0], xsnmaddqp[0], xsnmsubqp[0]

- VSX Scalar Quad-Precision Convert to Integer instructions:
  - xscvqpsdz, xscvqpswz, xscvqpudz, xscvqpuwz

- VSX Scalar Round Quad-Precision to Double-Extended-Precision (xsrqpxp)
- VSX Scalar Round to Quad-Precision Integer (xsrqpi)
- VSX Scalar Round to Quad-Precision Integer with Inexact (xsrqpix)
- VSX Scalar Convert with round Quad-Precision to Double-Precision format [using round to Odd] (xscvqdp[0])

do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

   - VXSNAN (if SNaN)
   - VXSI (if Infinity - Infinity)
   - VXDI (if Infinity ÷ Infinity)
   - VXZDZ (if Zero ÷ Zero)
   - VXIMZ (if Infinity × Zero)
   - VXSQRT (if Invalid Square Root)
   - VXCVI (if Invalid Integer Convert)

2. VSR[VRT+32] is not modified.

3. FR and FI are set to zero. FPRF is not modified.

For any of the following instructions,

- VSX Scalar Compare Ordered Quad-Precision (xscmpoqp)
- VSX Scalar Compare Unordered Quad-Precision (xscmpuqp)

do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

   - VXSNAN (if SNaN)
   - VXVC (if Invalid Compare)

2. FR, FI, and C are not modified. FPCC is set to reflect unordered.
For any of the following instructions,

VSX Scalar Convert Half-Precision to Double-Precision format (\texttt{xscvpdp})
VSX Scalar Convert with round Double-Precision to Half-Precision format (\texttt{xscvdp})

do the following.

1. \texttt{VXSN} is set to 1.
2. \texttt{VSR[XT]} is not modified.
3. \texttt{FR} and \texttt{FI} are set to 0. \texttt{FPRF} is not modified.

For any of the following instructions,

VSX Vector Convert Half-Precision to Single-Precision format (\texttt{xvchpsp})
VSX Vector Convert with round Single-Precision to Half-Precision format (\texttt{xvcsphp})

do the following.

1. \texttt{VXSN} is set to 1.
2. \texttt{VSR[XT]} is not modified.
3. \texttt{FR}, \texttt{FI}, and \texttt{FPRF} are not modified.

For any of the following instructions,

VSX Vector Floating-Point Arithmetic instructions:
VSX Vector Floating-Point Compare instructions:
VSX Vector DP-SP Conversion instructions:
VSX Vector Convert Floating-Point to Integer instructions:
VSX Vector Round to Floating-Point Integer instructions:

do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   \begin{itemize}
   \item \texttt{VXSN} (if SNaN)
   \item \texttt{VXSI} (if Infinity – Infinity)
   \item \texttt{VXDI} (if Infinity ÷ Infinity)
   \item \texttt{VXZD} (if Zero ÷ Zero)
   \item \texttt{VXIM} (if Infinity × Zero)
   \item \texttt{VXVC} (if Invalid Compare)
   \item \texttt{VXSQRT} (if Invalid Square Root)
   \item \texttt{VXCVI} (if Invalid Integer Convert)
   \end{itemize}
2. Update of \texttt{VSR[XT]} is suppressed for all vector elements.
3. \texttt{FR} and \texttt{FI} are unchanged.
4. \texttt{FPRF} is unchanged.
7.4.1.3 Action for VE=0

When Invalid Operation exception is disabled (VE=0) and an Invalid Operation exception occurs, the following actions are taken:

For the VSX Scalar Convert with round Double-Precision to Single-Precision format (xscvdpsp) instruction:

1. VXSNAN is set to 1.
2. The single-precision representation of a Quiet NaN is placed into word elements 0 and 1 of VSR[XT]. The contents of word elements 2 and 3 of VSR[XT] are set to 0.
3. FR and FI are set to 0.
4. FPRF is set to indicate the class of the result (Quiet NaN).

For the VSX Vector Single-Precision Arithmetic instructions, VSX Vector Single-Precision Maximum/Minimum instructions, the VSX Vector Convert with round Double-Precision to Single-Precision format (xvcvdpsp) instruction, and the VSX Vector Round to Single-Precision Integer instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   VXSNAN  (if SNaN)
   VXSI    (if Infinity – Infinity)
   VXDI    (if Infinity + Infinity)
   VXZDZ   (if Zero ÷ Zero)
   VXIMZ   (if Infinity × Zero)
   VXSQRT  (if Invalid Square Root)

2. The single-precision representation of a Quiet NaN is placed into its respective word element of VSR[XT], and for xvcvdpsp, is also placed into bits 32:63 of its respective doubleword element of VSR[XT].
3. FR, FI, and FPRF are not modified.

For the VSX Scalar Double-Precision Arithmetic instructions, VSX Scalar Double-Precision Maximum/Minimum instructions, the VSX Scalar Convert Single-Precision to Double-Precision format (xscvspdp) instruction, and the VSX Scalar Round to Double-Precision Integer instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   VXSNAN  (if SNaN)
   VXSI    (if Infinity – Infinity)
   VXDI    (if Infinity + Infinity)
   VXZDZ   (if Zero ÷ Zero)
   VXIMZ   (if Infinity × Zero)
   VXSQRT  (if Invalid Square Root)

2. The double-precision representation of a Quiet NaN is placed into doubleword element 0 of VSR[XT].
   The contents of doubleword element 1 of VSR[XT] are set to 0.
3. FR and FI are set to 0.
4. FPRF is set to indicate the class of the result (Quiet NaN).
For any of the following instructions,

VSX Scalar Quad-Precision Arithmetic instructions:
\[
\begin{align*}
\text{xssaddqp} & \text{[o]}, \text{xssdivqp} [\text{[o]}], \text{xssmulqp} [\text{[o]}], \text{xssqrtqp} [\text{[o]}], \text{xssubqp} [\text{[o]}] \\
\text{xsmaddqp} [\text{[o]}], \text{xsmsubqp} [\text{[o]}], \text{xsnmaddqp} [\text{[o]}], \text{xsnmsubqp} [\text{[o]}]
\end{align*}
\]

VSX Scalar Quad-Precision Round to Integer (xsqrpi)
VSX Scalar Quad-Precision Round to Integer with Inexact (xsqrpix)

do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

\[
\begin{align*}
\text{VXSNAN} & \quad \text{(if SNaN)} \\
\text{VXI SI} & \quad \text{(if Infinity \cdot \text{Infinity)}} \\
\text{VXI DI} & \quad \text{(if Infinity + \text{Infinity)}} \\
\text{VXZDZ} & \quad \text{(if Zero + Zero)} \\
\text{VXI MZ} & \quad \text{(if Infinity \times \text{Zero)}} \\
\text{VXSQRT} & \quad \text{(if Invalid Square Root)}
\end{align*}
\]

2. The quad-precision representation of a Quiet NaN is placed into VSR[VRT+32].

3. FR and FI are set to 0. FPRF is set to indicate the class of the result (Quiet NaN).

For vsx scalar round quad-precision to double-extended-precision (xsrqpxp), do the following.

1. VXSNAN is set to 1.

2. The Quiet NaN is placed into VSR[VRT+32] in quad-precision format.

3. FR and FI are set to 0. FPRF is set to indicate the class of the result (Quiet NaN).

For any of the following instructions,

VSX Scalar Compare Ordered Quad-Precision (xscmpoqp)
VSX Scalar Compare Unordered Quad-Precision (xscmpoqp)

do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

\[
\begin{align*}
\text{VXSNAN} & \quad \text{(if SNaN)} \\
\text{VXVC} & \quad \text{(if Invalid Compare)}
\end{align*}
\]

2. FR, FI and C are unchanged. FPCC is set to reflect unordered.

For vsx scalar convert with round quad-precision to double-precision format [using round to odd] (xscvqdpd[o]), do the following.

1. VXSNAN is set to 1.

2. The double-precision Quiet NaN result is placed into doubleword element 0 of VSR[VRT+32] in double-precision format.

\[
0x0000_0000_0000_0000
\]

is placed into doubleword element 1 of VSR[VRT+32].

3. FR and FI are set to 0. FPRF is set to indicate the class of the result (Quiet NaN).
For VSX Scalar Convert with round to zero Quad-Precision to Signed Doubleword format (xscvqpsdz), do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   VXSNAN  (if SNaN)
   VXCVI   (if Invalid Integer Convert)

2. 0x7FFF_FFFF_FFFF_FFFF is placed into doubleword element 0 of VSR[VRT+32] if the quad-precision operand in VSR[VRB+32] is a positive number or +Infinity.
   0x8000_0000_0000_0000 is placed into doubleword element 0 of VSR[VRT+32] if the quad-precision operand in VSR[VRB+32] is a negative number, -Infinity, or NaN.
   0x0000_0000_0000_0000 is placed into doubleword element 1 of VSR[VRT+32].

3. FR and FI are set to 0. FPRF is undefined.

For VSX Scalar Convert with round to zero Quad-Precision to Signed Word format (xscvqpswz), do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   VXSNAN  (if SNaN)
   VXCVI   (if Invalid Integer Convert)

2. 0x7FFF_FFFF is placed into word element 1 of VSR[VRT+32] if the quad-precision operand in VSR[VRB+32] is a positive number or +Infinity.
   0x8000_0000 is placed into word element 1 of VSR[VRT+32] if the quad-precision operand in VSR[VRB+32] is a negative number, -Infinity, or NaN.
   0x0000_0000 is placed into word elements 0, 2, and 3 of VSR[VRT+32].

3. FR and FI are set to 0. FPRF is undefined.

For VSX Scalar Convert with round to zero Quad-Precision to Unsigned Doubleword format (xscvqpudz), do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   VXSNAN  (if SNaN)
   VXCVI   (if Invalid Integer Convert)

2. 0xFFFF_FFFF_FFFF_FFFF is placed into doubleword element 0 of VSR[VRT+32] if the quad-precision operand in VSR[VRB+32] is a positive number or +Infinity.
   0x0000_0000_0000_0000 is placed into doubleword element 0 of VSR[VRT+32] if the quad-precision operand in VSR[VRB+32] is a negative number, -Infinity, or NaN.
   0x0000_0000_0000_0000 is placed into doubleword element 1 of VSR[VRT+32].

3. FR and FI are set to 0. FPRF is undefined.
For VSX Scalar Convert with round to zero Quad-Precision to Unsigned Word format (\texttt{xscvqpuwz}), do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   \begin{itemize}
   \item \texttt{VXSNAN} \hspace{1em} (if SNaN)
   \item \texttt{VXCVI} \hspace{1em} (if Invalid Integer Convert)
   \end{itemize}

2. 0xFFFF_FFFF is placed into word element 1 of \texttt{VSR[VRT+32]} if the quad-precision operand in \texttt{VSR[VRB+32]} is a positive number or +Infinity.

   \begin{itemize}
   \item 0x0000_0000 is placed into word element 1 of \texttt{VSR[VRT+32]} if the quad-precision operand in \texttt{VSR[VRB+32]} is a negative number, -Infinity, or NaN.
   \item 0x0000_0000 is placed into word elements 0, 2, and 3 of \texttt{VSR[VRT+32]}.
   \end{itemize}

3. \texttt{FR} and \texttt{FI} are set to 0. \texttt{FPRF} is undefined.

For VSX Scalar Convert with round Double-Precision to Half-Precision format (\texttt{xscvdphp}), do the following.

1. \texttt{VXSNAN} is set to 1.

2. The half-precision representation of a Quiet NaN is placed into the rightmost halfword of doubleword element 0 of \texttt{VSR[XT]}. The contents of the leftmost 3 halfwords of doubleword element 0 of \texttt{VSR[XT]} are set to 0. The contents of doubleword element 1 of \texttt{VSR[XT]} are set to 0.

3. \texttt{FR} and \texttt{FI} are set to 0. \texttt{FPRF} is set to indicate the class of the result (Quiet NaN).

For VSX Scalar Convert Half-Precision to Double-Precision format (\texttt{xscvhpdp}), do the following.

1. \texttt{VXSNAN} is set to 1.

2. The double-precision representation of a Quiet NaN is placed into doubleword element 0 of \texttt{VSR[XT]}. The contents of doubleword element 1 of \texttt{VSR[XT]} are set to 0.

3. \texttt{FR} and \texttt{FI} are set to 0. \texttt{FPRF} is set to indicate the class of the result (Quiet NaN).

For any of the following instructions,

\begin{itemize}
\item VSX Vector Double-Precision Arithmetic instructions
\item VSX Vector Double-Precision Maximum/Minimum instructions
\item VSX Vector Convert Single-Precision to Double-Precision format (\texttt{xvcvspdp})
\item VSX Vector Round to Double-Precision Integer instructions
\end{itemize}

do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

   \begin{itemize}
   \item \texttt{VXSNAN} \hspace{1em} (if SNaN)
   \item \texttt{VXISI} \hspace{1em} (if Infinity – Infinity)
   \item \texttt{VXIDI} \hspace{1em} (if Infinity ÷ Infinity)
   \item \texttt{VXZDZ} \hspace{1em} (if Zero ÷ Zero)
   \item \texttt{VXIMZ} \hspace{1em} (if Infinity × Zero)
   \item \texttt{VXSQRT} \hspace{1em} (if Invalid Square Root)
   \end{itemize}

2. The double-precision representation of a Quiet NaN is placed into its respective doubleword element of \texttt{VSR[XT]}.

3. \texttt{FR}, \texttt{FI}, and \texttt{FPRF} are not modified.
For the **VSX Scalar Convert with round to zero Double-Precision to Signed Doubleword format** (**xscvdpsxd**) instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   VXSNAN  (if SNaN)  
   VXCVI   (if Invalid Integer Convert)  

2. \texttt{0xFFF_FFFF_FFFF_FFFF} is placed into doubleword element 0 of \texttt{VSR[XT]} if the double-precision operand in doubleword element 0 of \texttt{VSR[XB]} is a positive number or +Infinity.

   \texttt{0x8000_0000_0000_0000} is placed into doubleword element 0 of \texttt{VSR[XT]} if the double-precision operand in doubleword element 0 of \texttt{VSR[XB]} is a negative number, -Infinity, or NaN.

   The contents of doubleword element 1 of \texttt{VSR[XT]} are set to 0.

3. \texttt{FR} and \texttt{FI} are set to 0.

4. FPRF is undefined.

For the **VSX Scalar Convert with round to zero Double-Precision to Unsigned Doubleword format** (**xscvpuxd**) instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

   VXSNAN  (if SNaN)  
   VXCVI   (if Invalid Integer Convert)  

2. \texttt{0xFFFF_FFFF_FFFF_FFFF} is placed into doubleword element 0 of \texttt{VSR[XT]} if the double-precision operand in doubleword element 0 of \texttt{VSR[XB]} is a positive number or +Infinity.

   \texttt{0x0000_0000_0000_0000} is placed into doubleword element 0 of \texttt{VSR[XT]} if the double-precision operand in doubleword element 0 of \texttt{VSR[XB]} is a negative number, -Infinity, or NaN.

   The contents of doubleword element 1 of \texttt{VSR[XT]} are set to 0.

3. \texttt{FR} and \texttt{FI} are set to 0.

4. FPRF is undefined.

For the **VSX Scalar Convert with round to zero Double-Precision to Signed Word format** (**xscvdpsxw**) instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

   VXSNAN  (if SNaN)  
   VXCVI   (if Invalid Integer Convert)  

2. \texttt{0xFFF_FFFF} is placed into word elements 0 and 1 of \texttt{VSR[XT]} if the double-precision operand in doubleword element 0 of \texttt{VSR[XB]} is a positive number or +Infinity.

   \texttt{0x8000_0000} is placed into word elements 0 and 1 of \texttt{VSR[XT]} if the double-precision operand in doubleword element 0 of \texttt{VSR[XB]} is a negative number, -Infinity, or NaN.

   The contents of word elements 2 and 3 of \texttt{VSR[XT]} are set to 0.

3. \texttt{FR} and \texttt{FI} are set to 0.

4. FPRF is undefined.
For the VSX Scalar Convert with round to zero Double-Precision to Unsigned Word format ($xscvdpuwxw$) instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   - VXSNAN  (if SNaN)
   - VXCVI  (if Invalid Integer Convert)

2. $0xFFFF_FFFF$ is placed into word elements 0 and 1 of $VSR[XT]$ if the double-precision operand in doubleword element 0 of $VSR[XB]$ is a positive number or $\pm\infty$.
   
   $0x0000_0000$ is placed into word elements 0 and 1 of $VSR[XT]$ if the double-precision operand in doubleword element 0 of $VSR[XB]$ is a negative number, $-\infty$, or NaN.
   
   The contents of word elements 2 and 3 of $VSR[XT]$ are set to 0.

3. $FR$ and $FI$ are set to 0.

4. FPRF is undefined.

For the VSX Vector Convert with round to zero Double-Precision to Signed Doubleword format ($xvcvdpsxd$) instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   - VXSNAN  (if SNaN)
   - VXCVI  (if Invalid Integer Convert)

2. $0x7FFF_FFFF_FFFF_FFFF$ is placed into doubleword element $i$ of $VSR[XT]$ if the double-precision operand in the corresponding doubleword element of $VSR[XB]$ is a positive number or $\pm\infty$.
   
   $0x8000_0000_0000_0000$ is placed into its respective doubleword element $i$ of $VSR[XT]$ if the double-precision operand in the corresponding doubleword element of $VSR[XB]$ is a negative number, $-\infty$, or NaN.

3. $FR$, $FI$, and FPRF are not modified.

For the VSX Vector Convert with round to zero Double-Precision to Unsigned Doubleword format ($xvcvdpuxd$) instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   - VXSNAN  (if SNaN)
   - VXCVI  (if Invalid Integer Convert)

2. $0xFFFF_FFFF_FFFF_FFFF$ is placed into doubleword element $i$ of $VSR[XT]$ if the double-precision operand in doubleword element $i$ of $VSR[XB]$ is a positive number or $\pm\infty$.
   
   $0x0000_0000_0000_0000$ is placed into doubleword element $i$ of $VSR[XT]$ if the double-precision operand in doubleword element $i$ of $VSR[XB]$ is a negative number, $-\infty$, or NaN.

3. $FR$, $FI$, and FPRF are not modified.
For the VSX Vector Convert with round to zero Double-Precision to Signed Word format (\texttt{xvcvdpsxw}) instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   \begin{itemize}
   \item \texttt{VXSNAN} \hspace{1em} (if SNaN)
   \item \texttt{VXCVI} \hspace{1em} (if Invalid Integer Convert)
   \end{itemize}

2. \texttt{0xFFF_FFFF} is placed into word elements \(i \times 2\) and \(i \times 2 + 1\) of VR[XT] if the double-precision operand in doubleword element \(i\) of VR[XB] is a positive number or +Infinity.

   \texttt{0x0000_0000} is placed into word elements \(i \times 2\) and \(i \times 2 + 1\) of VR[XT] if the double-precision operand in doubleword element \(i\) of VR[XB] is a negative number, -Infinity, or NaN.

3. \texttt{FR}, \texttt{FI}, and \texttt{FPRF} are not modified.

For the VSX Vector Convert with round to zero Double-Precision to Unsigned Word format (\texttt{xvcudpuxw}) instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   \begin{itemize}
   \item \texttt{VXSNAN} \hspace{1em} (if SNaN)
   \item \texttt{VXCVI} \hspace{1em} (if Invalid Integer Convert)
   \end{itemize}

2. \texttt{0xFFFF_FFFF} is placed into word elements \(i \times 2\) and \(i \times 2 + 1\) of VR[XT] if the double-precision operand in doubleword element \(i\) of VR[XB] is a positive number or +Infinity.

   \texttt{0x0000_0000} is placed into word elements \(i \times 2\) and \(i \times 2 + 1\) of VR[XT] if the double-precision operand in doubleword element \(i\) of VR[XB] is a negative number, -Infinity, or NaN.

3. \texttt{FR}, \texttt{FI}, and \texttt{FPRF} are not modified.

For the VSX Vector Convert with round to zero Single-Precision to Signed Doubleword format (\texttt{xvcvpsxd}) instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   \begin{itemize}
   \item \texttt{VXSNAN} \hspace{1em} (if SNaN)
   \item \texttt{VXCVI} \hspace{1em} (if Invalid Integer Convert)
   \end{itemize}

2. \texttt{0xFFF_FFFF_FFFF_FFFF} is placed into doubleword element \(i\) of VR[XT] if the single-precision operand in word element \(i \times 2\) of VR[XB] is a positive number or +Infinity.

   \texttt{0x8000_0000_0000_0000} is placed into doubleword element \(i\) of VR[XT] if the single-precision operand in word element \(i \times 2\) of VR[XB] is a negative number, -Infinity, or NaN.

3. \texttt{FR}, \texttt{FI}, and \texttt{FPRF} are not modified.
For the VSX Vector Convert with round to zero Single-Precision to Unsigned Doubleword format (xvcvspuxd) instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   \[
   \text{VXSNAN (if SNaN)}
   \]
   \[
   \text{VXCVI (if Invalid Integer Convert)}
   \]

2. \(0xFFFF_FFFF_FFFF_FFFF\) is placed into doubleword element \(i\) of \(\text{VSR}[\text{XT}]\) if the single-precision operand in word element \(i \times 2\) of \(\text{VSR}[\text{XB}]\) is a positive number or +Infinity.

   \(0x0000_0000_0000_0000\) is placed into doubleword element \(i\) of \(\text{VSR}[\text{XT}]\) if the single-precision operand in word element \(i \times 2\) of \(\text{VSR}[\text{XB}]\) is a negative number, -Infinity, or NaN.

3. \(\text{FR}, \text{FI}, \text{and FPRAF}\) are not modified.

For the VSX Vector Convert with round to zero Single-Precision to Signed Word format (xvcvpsxw) instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   \[
   \text{VXSNAN (if SNaN)}
   \]
   \[
   \text{VXCVI (if Invalid Integer Convert)}
   \]

2. \(0x7FFF_FFFF\) is placed into word element \(i\) of \(\text{VSR}[\text{XT}]\) if the single-precision operand in word element \(i\) of \(\text{VSR}[\text{XB}]\) is a positive number or +Infinity.

   \(0x8000_0000\) is placed into word element \(i\) of \(\text{VSR}[\text{XT}]\) if the single-precision operand in word element \(i\) of \(\text{VSR}[\text{XB}]\) is a negative number, -Infinity, or NaN.

3. \(\text{FR}, \text{FI}, \text{and FPRAF}\) are not modified.

For the VSX Vector Convert with round to zero Single-Precision to Unsigned Word format (xvcvpsuxw) instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   \[
   \text{VXSNAN (if SNaN)}
   \]
   \[
   \text{VXCVI (if Invalid Integer Convert)}
   \]

2. \(0xFFFF_FFFF\) is placed into word element \(i\) of \(\text{VSR}[\text{XT}]\) if the single-precision operand in the corresponding word element \(2 \times i\) of \(\text{VSR}[\text{XB}]\) is a positive number or +Infinity.

   \(0x0000_0000\) is placed into word element \(i\) of \(\text{VSR}[\text{XT}]\) if the single-precision operand in word element \(2 \times i\) of \(\text{VSR}[\text{XB}]\) is a negative number, -Infinity, or NaN.

3. \(\text{FR}, \text{FI}, \text{and FPRAF}\) are not modified.

For the VSX Scalar Floating-Point Compare instructions, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   \[
   \text{VXSNAN (if SNaN)}
   \]
   \[
   \text{VXCVI (if Invalid Integer Convert)}
   \]

2. \(\text{FR}, \text{FI} \), and \(\text{FPRAF}\) are unchanged.

3. \(\text{FPCC}\) is set to reflect unordered.
For the VSX Vector Compare Single-Precision instructions, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   VXSNAN (if SNaN)
   VXCVI (if Invalid Integer Convert)

2. 0x0000_0000 is placed into its respective word element of VSR[XT].

3. FR, FI, and FPRF are not modified.

For the Vector Double-Precision Compare instructions, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
   
   VXSNAN (if SNaN)
   VXCVI (if Invalid Integer Convert)

2. 0x0000_0000_0000_0000 is placed into its respective doubleword element of VSR[XT].

3. FR, FI, and FPRF are not modified.

For VSX Vector Convert with round Single-Precision to Half-Precision format (xvcvsphp), do the following.

1. VXSNAN is set to 1.

2. The half-precision representation of a Quiet NaN is placed into the rightmost halfword of its respective word element of VSR[XT]. The contents of the leftmost halfword of its respective word element of VSR[XT] are set to 0.

3. FR, FI, and FPRF are not modified.

For VSX Vector Convert Half-Precision to Single-Precision format (xvcvhpsp), do the following.

1. VXSNAN is set to 1.

2. The half-precision representation of a Quiet NaN is placed into the rightmost halfword of its respective word element of VSR[XT]. The contents of the leftmost halfword of its respective word element of VSR[XT] are set to 0.

3. FR, FI, and FPRF are not modified.
7.4.2 Floating-Point Zero Divide Exception

7.4.2.1 Definition

A Zero Divide exception occurs when a VSX Floating-Point Divide instruction is executed with a zero divisor value and a finite nonzero dividend value.

A Zero Divide exception also occurs when a VSX Floating-Point Reciprocal Estimate instruction or a VSX Floating-Point Reciprocal Square Root Estimate instruction is executed with an operand value of zero.

The action to be taken depends on the setting of the Zero Divide Exception Enable bit of the FPSCR.

7.4.2.2 Action for ZE=1

When Zero Divide exception is enabled (ZE=1) and a Zero Divide exception occurs, the following actions are taken:

For any of the following instructions,

- VSX Scalar Divide Double-Precision \((xsdivdp)\)
- VSX Scalar Divide Single-Precision \((xsdivsp)\)
- VSX Scalar Divide Quad-Precision \((xsdivqp)\)
- VSX Scalar Reciprocal Estimate Double-Precision \((xsredp)\)
- VSX Scalar Reciprocal Estimate Single-Precision \((xsresp)\)
- VSX Scalar Reciprocal Square Root Estimate Double-Precision \((xsrsqtedp)\)
- VSX Scalar Reciprocal Square Root Estimate Single-Precision \((xsrsqrtesp)\)

do the following.

1. \(ZX\) is set to 1.
2. \(VSR[XT]\) is not modified.
3. \(FR\) and \(FI\) are set to 0. \(FPRF\) is unchanged.

For any of the following instructions,

- VSX Vector Divide Double-Precision \((xvdivdp)\)
- VSX Vector Divide Single-Precision \((xvdivsp)\)
- VSX Vector Reciprocal Estimate Double-Precision \((xvredp)\)
- VSX Vector Reciprocal Estimate Single-Precision \((xvresp)\)
- VSX Vector Reciprocal Square Root Estimate Double-Precision \((xvrsqtedp)\)
- VSX Vector Reciprocal Square Root Estimate Single-Precision \((xvrsqrtesp)\)

do the following.

1. \(ZX\) is set to 1.
2. \(VSR[XT]\) is not modified.
3. \(FR\) and \(FI\) are unchanged. \(FPRF\) is unchanged.
7.4.2.3 Action for ZE=0

When Zero Divide exception is disabled (ZE=0) and a Zero Divide exception occurs, the following actions are taken:

For any of the following instructions,

VSX Scalar Divide Double-Precision (xsdivdp)  
VSX Scalar Divide Single-Precision (xsdivsp)

do the following.

1. \(Z_X\) is set to 1.

2. An Infinity, having a sign determined by the XOR of the signs of the source operands, is placed into doubleword element 0 of \(VSR[XT]\) in double-precision format. The contents of doubleword element 1 of \(VSR[XT]\) are set to 0.

3. \(FR\) and \(FI\) are set to 0. \(FPRF\) is set to indicate the class and sign of the result (± Infinity).

For VSX Scalar Divide Quad-Precision (xsdivqdp), do the following.

1. \(Z_X\) is set to 1.

2. An Infinity, having a sign determined by the XOR of the signs of the source operands, is placed into \(VSR[VRT+32]\) in quad-precision format.

3. \(FR\) and \(FI\) are set to 0. \(FPRF\) is set to indicate the class and sign of the result (± Infinity).

For VSX Vector Divide Double-Precision (xdivdp), do the following.

1. \(Z_X\) is set to 1.

2. For each vector element causing a Zero Divide exception, an Infinity, having a sign determined by the XOR of the signs of the source operands, is placed into its respective doubleword element of \(VSR[XT]\) in double-precision format.

3. \(FR, FI\), and \(FPRF\) are not modified.

For VSX Vector Divide Single-Precision (xdivsp), do the following.

1. \(Z_X\) is set to 1.

2. For each vector element causing a Zero Divide exception, an Infinity, having a sign determined by the XOR of the signs of the source operands, is placed into its respective word element of \(VSR[XT]\) in single-precision format.

3. \(FR, FI\), and \(FPRF\) are not modified.
For any of the following instructions,

VSX Scalar Reciprocal Estimate Double-Precision (xsredp)
VSX Scalar Reciprocal Estimate Single-Precision (xsresp)

VSX Scalar Reciprocal Square Root Estimate Double-Precision (xsrsqrtedp)
VSX Scalar Reciprocal Square Root Estimate Single-Precision (xsrsqrtesp)

do the following.

1. \( ZX \) is set to 1.

2. An Infinity, having the sign of the source operand, is placed into doubleword element 0 of \( VSR[XT] \) in double-precision format. The contents of doubleword element 1 of \( VSR[XT] \) are set to 0.

3. \( FR \) and \( FI \) are set to 0. \( FPRF \) is set to indicate the class and sign of the result (± Infinity).

For any of the following instructions,

VSX Vector Reciprocal Estimate Double-Precision (xsredp)
VSX Vector Reciprocal Square Root Estimate Double-Precision (xsrsqrtedp)

do the following.

1. \( ZX \) is set to 1.

2. For each vector element causing a Zero Divide exception, an Infinity, having the sign of the source operand, is placed into its respective doubleword element of \( VSR[XT] \) in double-precision format.

3. \( FR \), \( FI \), and \( FPRF \) are not modified.

For any of the following instructions,

VSX Vector Reciprocal Estimate Single-Precision (xsresp)
VSX Vector Reciprocal Square Root Estimate Single-Precision (xsrsqrtesp)

do the following.

1. \( ZX \) is set to 1.

2. For each vector element causing a Zero Divide exception, an Infinity, having the sign of the source operand, is placed into its respective word element of \( VSR[XT] \) in single-precision format.

3. \( FR \), \( FI \), and \( FPRF \) are not modified.
7.4.3 Floating-Point Overflow Exception

7.4.3.1 Definition

An Overflow exception occurs when the magnitude of what would have been the rounded result if the exponent range were unbounded exceeds that of the largest finite number of the specified result precision.

The action to be taken depends on the setting of the Overflow Exception Enable bit of the FPSCR.

7.4.3.2 Action for OE=1

When Overflow exception is enabled (OE=1) and an Overflow exception occurs, the following actions are taken:

For the VSX Vector round and Convert Double-Precision to Single-Precision format (xscvdpsp) instruction:

1. OX is set to 1.
2. If the unbiased exponent of the normalized intermediate result is less than or equal to 318 (Emax+192), the exponent is adjusted by subtracting 192. Otherwise the result is undefined.
3. The adjusted rounded result is placed into word elements 0 and 1 of VSR[XT] in single-precision format. The contents of word elements 2 and 3 of VSR[XT] are set to 0.
4. Unless the result is undefined, FPRF is set to indicate the class and sign of the result (±Normal Number).

For any of the following instructions,

VSX Scalar Double-Precision Arithmetic instructions
xsadddp, xsdivdp, xsmuldp, xssubdp
xsmaddadp, xsmaddmdp, xsmsubadp, xsmsubmdp
xsnmaddadp, xsnmaddmdp, xsnmsubadp, xsnmsubmdp

VSX Vector Reciprocal Estimate Double-Precision (xsredp)

do the following.

1. OX is set to 1.
2. The exponent of the normalized intermediate result is adjusted by subtracting 1536.
3. The adjusted rounded result is placed into doubleword element 0 of VSR[XT] in double-precision format. The contents of doubleword element 1 of VSR[XT] are set to 0.
4. FPRF is set to indicate the class and sign of the result (±Normal Number).
For any of the following instructions,

**VSX Scalar Single-Precision Arithmetic instructions**
- xsaddsp, xsdivsp, xsmulsp, xssubsp
- xsmaddasp, xsmaddmsp, xsmsubasp, xsmsubmsp
- xsnmaddasp, xsnmaddmsp, xsnmsubasp, xsnmsubmsp

**VSX Scalar Reciprocal Estimate Single-Precision (xsresp)**

**VSX Vector Reciprocal Square Root Estimate Single-Precision (xrsqrtresp)**

**VSX Scalar Round to Single-Precision (xrsrp)**

do the following.

1. OX is set to 1.
2. The exponent is adjusted by subtracting 192.
3. The adjusted and rounded result is placed into doubleword element 0 of VSR[XT] in double-precision format. The contents of doubleword element 1 of VSR[XT] are set to 0.
4. FPRF is set to indicate the class and sign of the result (±Normal Number).

For any of the following instructions,

**VSX Scalar Quad-Precision Arithmetic instructions**
- xsaddqp[0], xsdivqp[0], xsmulqp[0], xssqrtqp[0], xssubqp[0]
- xsmaddqp[0], xsmsubqp[0], xsnmaddqp[0], xsnmsubqp[0]

**VSX Scalar Round Quad-Precision to Double-Extended-Precision (xsrqpxp)**

do the following.

1. OX is set to 1.
2. The exponent is adjusted by subtracting 24576.
3. The adjusted, rounded result is placed into VSR[VRT+32] in quad-precision format.
4. Unless the result is undefined, FPRF is set to indicate the class and sign of the result (±Normal Number).

For **VSX Scalar Convert with round Quad-Precision to Double-Precision format [using round to Odd] (xscvqpdsp)**, do the following.

1. OX is set to 1.
2. The exponent is adjusted by subtracting 1536. If the adjusted exponent is greater than +1023 (Emx), the result is undefined.
3. The adjusted, rounded result is placed into doubleword element 0 of VSR[VRT+32] in double-precision format.
   
   0x0000.0000_0000.0000 is placed into doubleword element 1 of VSR[VRT+32].
4. Unless the result is undefined, FPRF is set to indicate the class and sign of the result (±Normal Number).
For VSX Scalar Convert with round Double-Precision to Half-Precision format (**xscvdphp**), do the following.

1. **OX** is set to 1.
2. The exponent is adjusted by subtracting 24. If the adjusted exponent is greater than +15 (\(E_{\max}\)), the result is undefined.
3. The adjusted, rounded result is placed into rightmost halfword of doubleword element 0 of **VSR[XT]** in half-precision format.
   - The contents of the leftmost 3 halfwords of doubleword element 0 of **VSR[XT]** are set to 0.
   - The contents of doubleword element 1 of **VSR[XT]** are set to 0.
4. Unless the result is undefined, **FPRF** is set to indicate the class and sign of the result (±Normal Number).

For any of the following instructions,

- **VSX Vector Double-Precision Arithmetic instructions**
  - **xvadddp, xvdivdp, xvmuldp, xvredp, xvsubdp,**
  - **xvmaddadp, xsmaddmdp, xvmsubadp, xvmsubmdp,**
  - **xvnaddadp, xvnaddmdp, xvnmsubadp, xvnmsubmdp**

- **VSX Vector Single-Precision Arithmetic instructions**
  - **xvaddsp, xvdivsp, xvmulsp, xvresp, xvsubsp**
  - **xvmaddasp, xvmaddmsp, xvmsubasp, xvmsubmsp**
  - **xvnaddasp, xvnaddmsp, xvnmsubasp, xvnmsubmsp**

- **VSX Vector round and Convert Double-Precision to Single-Precision format (**xvcvdpsp**)**

  do the following.

1. **OX** is set to 1.
2. **VSR[XT]** is not modified.
3. **FR, FI**, and **FPRF** are not modified.

For VSX Vector Convert with round Single-Precision to Half-Precision format (**xvcvsphp**), do the following.

1. **OX** is set to 1.
2. **VSR[XT]** is not modified.
3. **FR, FI**, and **FPRF** are not modified.
7.4.3.3 Action for OE=0

When Overflow exception is disabled (OE=0) and an Overflow exception occurs, the following actions are taken:

1. OX and XX are set to 1.
2. The result is determined by the rounding mode (RN) and the sign of the intermediate result as follows:

   **Round to Nearest Even**
   For negative overflow, the result is -Infinity.
   For positive overflow, the result is +Infinity.

   **Round toward Zero**
   For negative overflow, the result is the format’s most negative finite number.
   For positive overflow, the result is the format’s most positive finite number.

   **Round toward +Infinity**
   For negative overflow, the result is the format’s most negative finite number.
   For positive overflow, the result is +Infinity.

   **Round toward -Infinity**
   For negative overflow, the result is -Infinity.
   For positive overflow, the result is the format’s most positive finite number.

For VSX Scalar round and Convert Double-Precision to Single-Precision format (xscvdpsp):

3. The result is placed into word elements 0 and 1 of VSR[XT] as a single-precision value. The contents of word elements 2 and 3 of VSR[XT] are set to 0.
4. FR is undefined. FI is set to 1. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

**VSX Scalar Double-Precision Arithmetic instructions**
xsaddp, xsdivp, xsmulp, xsredp, xssubdp
xsmaddadp, xsmaddmdp, xsmsubadp, xsmsubmdp
xsnmaddadp, xsnmaddmdp, xsnmsubadp, xsnmsubmdp

**VSX Scalar Single-Precision Arithmetic instructions**
xsaddsp, xsdivsp, xsmulsp, xssresp, xssubsp
xsmaddasp, xsmaddmsp, xsmsubasp, xsmsubmsp
xsnmaddasp, xsnmaddmsp, xsnmsubasp, xsnmsubmsp

do the following.

3. The result is placed into doubleword element 0 of VSR[XT] as a double-precision value. The contents of doubleword element 1 of VSR[XT] are set to 0.
4. FR is undefined. FI is set to 1. FPRF is set to indicate the class and sign of the result.
For any of the following instructions,

**VSX Scalar Quad-Precision Arithmetic instructions**
xsaddqp[0], xsdivqp[0], xsmulqp[0], xssubqp[0]
xsmaddqp[0], xsmsubqp[0], xsnaddqp[0], xsnsubqp[0]

**VSX Scalar Quad-Precision Round to Double-Extended-Precision (xsrpqxp)**
do the following.

3. The result is placed into VSR[VRT+32] in quad-precision format.

4. FR is undefined. FI is set to 1. FPRF is set to indicate the class and sign of the result.

For **VSX Scalar Convert with round Quad-Precision to Double-Precision format (xscvqdp)**, do the following.

3. The result is placed into doubleword element 0 of VSR[VRT+32] as a double-precision value.

   0x0000_0000_0000_0000 is placed into doubleword element 1 of VSR[VRT+32].

4. FR is undefined. FI is set to 1. FPRF is set to indicate the class and sign of the result.

For **VSX Scalar Convert with round Double-Precision to Half-Precision format (xscvdphp)**, do the following.

3. The result is placed into the rightmost halfword of doubleword element 0 of VSR[XT] as a half-precision value.

   The contents of the leftmost 3 halfwords of doubleword element 0 of VSR[XT] are set to 0.

   The contents of doubleword element 1 of VSR[XT] are set to 0.

4. FR is undefined. FI is set to 1. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

For **VSX Vector Double-Precision Arithmetic instructions**
xvadddp, xvdivdp, xvmuldp, xvredp, xvsbldp
xvmaddadp, xvmaddmdp, xvmsubadp, xvmsubmdp
xvnaddadp, xvnaddmdp, xvnsubadp, xvnsubmdp
do the following.

3. For each vector element causing an Overflow exception, the result is placed into its respective doubleword element of VSR[XT] in double-precision format.

4. FR, FI, and FPRF are not modified.
For any of the following instructions,

VSX Vector Single-Precision Arithmetic instructions
\[ xvaddsp, xvdivsp, xvmuls, xvresp, xvsbsp \]
\[ xvmaddsp, xvmaddmsp, xvmsubasp, xvmsubmsp \]
\[ xvnmadsp, xvnmadmsp, xvnmsubasp, xvnmsubmsp \]

VSX Vector round and Convert Double-Precision to Single-Precision format \((xvcvdpsp)\)
do the following.

3. For each vector element causing an Overflow exception, the result is placed into its respective word element of \(VSR[XT]\) in single-precision format, and for \(xvcvdpsp\), is also placed into bits 32:63 of its respective doubleword element of \(VSX[XT]\).

4. \(FR, FI, \) and \(FPRF\) are not modified.

For VSX Vector Convert with round Single-Precision to Half-Precision format \((xvcvsphp)\), do the following.

3. For each vector element causing an Overflow exception, the result is placed into the rightmost halfword of its respective word element of \(VSR[XT]\) in half-precision format.

The contents of the leftmost halfword of its respective word element of \(VSR[XT]\) are set to 0.

4. \(FR, FI, \) and \(FPRF\) are not modified.
7.4.4 Floating-Point Underflow Exception

7.4.4.1 Definition

Underflow exception is defined separately for the enabled and disabled states:

**Enabled:**
Underflow occurs when the intermediate result is “Tiny”.

**Disabled:**
Underflow occurs when the intermediate result is “Tiny” and there is “Loss of Accuracy”.

A tiny result is detected before rounding, when a nonzero intermediate result computed as though both the precision and the exponent range were unbounded would be less in magnitude than the smallest normalized number.

If the intermediate result is tiny and Underflow exception is disabled (\( \text{UE}=0 \)), the intermediate result is denormalized (see Section 7.3.2.4, “Normalization and Denormalization” on page 513) and rounded (see Section 7.3.2.6, “Rounding” on page 518) before being placed into the target VSR.

*Loss of accuracy* is detected when the delivered result value differs from what would have been computed were both the precision and the exponent range unbounded.

The action to be taken depends on the setting of the Underflow Exception Enable bit of the FPSCR.

7.4.4.2 Action for UE=1

When Underflow exception is enabled (\( \text{UE}=1 \)) and an Underflow exception occurs, the following actions are taken:

For VSX Scalar round and Convert Double-Precision to Single-Precision format (\( \text{xscvdpsp} \)), do the following.

1. \( \text{UX} \) is set to 1.

2. The exponent of the normalized intermediate result is adjusted by adding 192. If the adjusted unbiased exponent is less than \(-126\) (\( \text{E}_{\text{min}} \)), the result is undefined.

3. The adjusted rounded result is placed into word elements 0 and 1 of \( \text{VSR}[\text{XT}] \) in single-precision format. The contents of word elements 2 and 3 of \( \text{VSR}[\text{XT}] \) are undefined.

4. Unless the result is undefined, \( \text{FPRF} \) is set to indicate the class and sign of the result (\( \pm\text{Normal Number} \)).
For any of the following instructions,

**VSX Scalar Double-Precision Arithmetic instructions**

- xsadddp, xsdivdp, xsmuldp, xssubdp
- xsaddadp, xsaddmdp, xsmaddadp, xssubadp
- xsmaddadp, xsmsubadp, xsmsubmdp

**VSX Scalar Double-Precision Reciprocal Estimate (xsredp)**

do the following.

1. UX is set to 1.
2. The exponent of the normalized intermediate result is adjusted by adding 1536.
3. The adjusted rounded result is placed into word elements 0 and 1 of VSR[XT] in single-precision format. The contents of word elements 2 and 3 of VSR[XT] are set to 0
4. FPRF is set to indicate the class and sign of the result (±Normal Number).

For any of the following instructions,

**VSX Scalar Quad-Precision Arithmetic instructions**

- xsaddqp, xsdivqp, xsmulqp, xssubqp
- xsaddadp, xsaddmdp, xsmaddadp, xssubadp
- xsmaddadp, xsmsubadp, xsmsubmdp

**VSX Scalar Round Quad-Precision to Double-Extended-Precision (xsrqpxp)**

do the following.

1. UX is set to 1.
2. The exponent of the normalized intermediate result is adjusted by adding 24576.
3. The adjusted, rounded result is placed into VSR[VRT+32] in quad-precision format.
4. FPRF is set to indicate the class and sign of the result (±Normal Number).

For **VSX Scalar Convert with round Quad-Precision to Double-Precision format [using round to Odd]** (xscvqdp[O]), do the following.

1. UX is set to 1.
2. The exponent of the normalized intermediate result is adjusted by adding 1536. If the adjusted unbiased exponent is less than -1022 (Emi n), the result is undefined.
3. The adjusted, rounded result is placed into doubleword element 0 of VSR[VRT+32] in double-precision format.

4. Unless the result is undefined, FPRF is set to indicate the class and sign of the result (±Normal Number).
For any of the following instructions,

**VSX Scalar Single-Precision Arithmetic instructions**
- `xsaddsp`, `xsdivsp`, `xsmulsp`, `xssubsp`
- `xsmaddasp`, `xsmaddmsp`, `xsmsubasp`, `xsmsubmsp`
- `xsnmaddasp`, `xsnmaddmsp`, `xsnmsubasp`, `xsnmsubmsp`

**VSX Scalar Single-Precision Reciprocal Estimate (xsresp)**

do the following.

1. `UX` is set to 1.
2. The exponent of the normalized intermediate result is adjusted by adding 192. If the adjusted unbiased exponent is less than \(-126\) (\(E_{\text{min}}\)), the result is undefined.
3. The adjusted rounded result is placed into doubleword element 0 of \(\text{VSR}[\text{XT}]\) in double-precision format. The contents of doubleword element 1 of \(\text{VSR}[\text{XT}]\) are set to 0.
4. Unless the result is undefined, \(\text{FPRF}\) is set to indicate the class and sign of the result (\(\pm \text{Normal Number}\)).

---

**Programming Note**

The FR and FI bits are provided to allow the system floating-point enabled exception error handler, when invoked because of an Underflow exception, to simulate a “trap disabled” environment. That is, the FR and FI bits allow the system floating-point enabled exception error handler to unround the result, thus allowing the result to be denormalized and correctly rounded.

For **VSX Scalar Convert with round Double-Precision to Half-Precision with round (xscvdphp)**, do the following.

1. `UX` is set to 1.
2. The exponent of the normalized intermediate result is adjusted by adding 24. If the adjusted unbiased exponent is less than \(-14\), the result is undefined.
3. The adjusted, rounded result is placed into rightmost halfword of doubleword element 0 of \(\text{VSR}[\text{XT}]\) in half-precision format.

   The contents of the leftmost 3 halfwords of doubleword element 0 of \(\text{VSR}[\text{XT}]\) are set to 0.

   The contents of doubleword element 1 of \(\text{VSR}[\text{XT}]\) are set to 0.
4. Unless the result is undefined, \(\text{FPRF}\) is set to indicate the class and sign of the result (\(\pm \text{Normal Number}\)).
For any of the following instructions,

**VSX Vector Double-Precision Arithmetic instructions**
- `xvadddp`, `xvdvdp`, `xvmuldp`, `xvsubdp`
- `xvmaddadp`, `xvmaddmdp`, `xvmsubadp`, `xvmsubmdp`
- `xvnaddadp`, `xvnaddmdp`, `xvnmsubadp`, `xvnmsubmdp`

**VSX Vector Single-Precision Arithmetic instructions**
- `xvadsp`, `xvdvsp`, `xvmulp`, `xvsbisp`
- `xvmaddasp`, `xvmaddmsp`, `xvmsubasp`, `xvmsubmsp`
- `xvnmaddasp`, `xvnaddmsp`, `xvnmsubasp`, `xvnmsubmsp`

**VSX Vector Reciprocal Estimate Double-Precision** (`xvredp`)
**VSX Vector Reciprocal Estimate Single-Precision** (`xvresp`)

**VSX Vector round and Convert Double-Precision to Single-Precision format** (`xvcvdpsp`)
**VSX Vector Convert with round Single-Precision to Half-Precision format** (`xvcvspshp`)

do the following.

1. `UX` is set to 1.
2. `VSR[XT]` is not modified.
3. `FR`, `FI`, and `FPRF` are not modified.

### 7.4.4.3 Action for UE=0

When Underflow exception is disabled (`UE=0`) and an Underflow exception occurs, the following actions are taken:

For **VSX Scalar round and Convert Double-Precision to Single-Precision format** (`xsvcdpshp`), do the following.

1. `UX` is set to 1.
2. The result is placed into word elements 0 and 1 of `VSR[XT]` as a single-precision value. The contents of word elements 2 and 3 of `VSR[XT]` are set to 0.
3. `FPRF` is set to indicate the class and sign of the result.

For any of the following instructions,

**VSX Scalar Double-Precision Arithmetic instructions**
- `xsadddp`, `xsdvdp`, `xsmuldp`, `xssubdp`
- `xsmsaddadp`, `xsmsaddmdp`, `xsmssubadp`, `xsmsubmdp`
- `xsmsnaddadp`, `xsmsnaddmdp`, `xsmsnmsubadp`, `xsmsnmsubmdp`

**VSX Scalar Single-Precision Arithmetic instructions**
- `xsaddsp`, `xsdvsp`, `xsmulsp`, `xssubsp`
- `xsmsaddasp`, `xsmsaddmsp`, `xsmssubasp`, `xsmsubmsp`
- `xsmsnaddasp`, `xsmsnaddmsp`, `xsmsnmsubasp`, `xsmsnmsubmsp`

**VSX Scalar Reciprocal Estimate Double-Precision** (`xsredp`)
**VSX Scalar Reciprocal Estimate Single-Precision** (`xsresp`)
do the following.

1. UX is set to 1.

2. The result is placed into doubleword element 0 of \(VSR[XT]\) in double-precision format. The contents of doubleword element 1 of \(VSR[XT]\) are set to 0.

3. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

\[
\text{VSX Scalar Quad-Precision Arithmetic instructions} \\
\text{xsaddqp}[o], \text{xsdvigqp}[o], \text{xsmulqp}[o], \text{xssubqp}[o] \\
\text{xsmaddqp}[o], \text{xsmsubqp}[o], \text{xsnmaddqp}[o], \text{xsnmsubqp}[o]
\]

\[
\text{VSX Scalar Round Quad-Precision to Double-Extended-Precision (xsrqpxp)}
\]

do the following.

1. UX is set to 1.

2. The result is placed into \(VSR[VRT+32]\) in quad-precision format.

3. FPRF is set to indicate the class and sign of the result.

For \text{VSX Scalar Convert with round Quad-Precision to Double-Precision format (xscvqdp)}, do the following.

1. UX is set to 1.

2. The result is placed into doubleword element 0 of \(VSR[VRT+32]\) in double-precision format.

\[
0x0000_0000_0000_0000 
\]

is placed into doubleword element 1 of \(VSR[VRT+32]\).

3. FPRF is set to indicate the class and sign of the result.

For \text{VSX Scalar Convert with round Double-Precision to Half-Precision format (xscvdphp)}, do the following.

1. UX is set to 1.

2. The result is placed into the rightmost halfword of doubleword element 0 of \(VSR[XT]\) as a half-precision value.

   The contents of the leftmost 3 halfwords of doubleword element 0 of \(VSR[XT]\) are set to 0.

   The contents of doubleword element 1 of \(VSR[XT]\) are set to 0.

3. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

\[
\text{VSX Vector Double-Precision Arithmetic instructions} \\
xvadddp, xvdivdp, xvmuldp, xsvsubdp \\
xvmaddadp, xvmaddmdp, xvmsubadp, xvmsubmdp \\
xvnmaddadp, xvnmaddmdp, xvnmsubadp, xvnmsubmdp
\]

\[
\text{VSX Vector Reciprocal Estimate Double-Precision (xvredp)}
\]
do the following.

1. UX is set to 1.

2. For each vector element causing an Underflow exception, the result is placed into its respective doubleword element of VSR[XT] in double-precision format.

3. FR, FI, and FPRF are not modified.

For any of the following instructions,

- **VSX Vector Single-Precision Arithmetic instructions**
  - xvaddsp, xdivsp, xvmulp, xvsbsp
  - xvmaddsp, xvmaddmsp, xvmsubasp, xvmsubmsp
  - xvnaddasp, xvnaddmsp, xvnsubasp, xvnsubmsp

- **VSX Vector Reciprocal Estimate Single-Precision (xvresp)**

- **VSX Vector round and Convert Double-Precision to Single-Precision format (xvcvdpsp)**

  do the following.

  1. UX is set to 1.

  2. For each vector element causing an Underflow exception, the result is placed into its respective word element of VSR[XT] in single-precision format, and for xvcvdpsp, is also placed into bits 32:63 of its respective doubleword element of VSR[XT].

  3. FR, FI, and FPRF are not modified.

For **VSX Vector Convert with round Single-Precision to Half-Precision format (xvcvshp)**, do the following.

  1. UX is set to 1.

  2. For each vector element causing an Underflow exception, the result is placed into the rightmost halfword of its respective word element of VSR[XT] in half-precision format.

     The contents of the leftmost halfword of its respective word element of VSR[XT] are set to 0.

  3. FR, FI, and FPRF are not modified.
7.4.5 Floating-Point Inexact Exception

7.4.5.1 Definition

An Inexact exception occurs when one of two conditions occur during rounding:

1. The rounded result differs from the intermediate result assuming both the precision and the exponent range of the intermediate result to be unbounded. In this case the result is said to be inexact. (If the rounding causes an enabled Overflow exception or an enabled Underflow exception, an Inexact exception also occurs only if the significands of the rounded result and the intermediate result differ.)

2. The rounded result overflows and Overflow exception is disabled.

The action to be taken depends on the setting of the Inexact Exception Enable bit of the FPSCR.

7.4.5.2 Action for XE=1

When Inexact exception is enabled (\( UE=1 \)) and an Inexact exception occurs, the following actions are taken:

For the \textit{VSX Scalar round and Convert Double-Precision to Single-Precision format} (\texttt{xscvdpsp}) instruction, do the following.

1. \texttt{XX} is set to 1.
2. The result is placed into word elements 0 and 1 of \texttt{VSR[XT]} in single-precision format. The contents of word elements 2-3 of \texttt{VSR[XT]} are set to 0.
3. \texttt{FPRF} is set to indicate the class and sign of the result.

For any of the following instructions,

- \texttt{xsadddp, xssubdp, xsmuldp, xsdivdp, xsqrtdp}
- \texttt{xsmaddadp, xsmaddmdp, xmssubadp, xmssubmdp}
- \texttt{xsnmaddadp, xsnmaddmdp, xsnmsubadp, xsnmsubmdp}

- \texttt{xssaddsp, xssubsp, xsmulsp, xsdivsp, xsqrtspsp}
- \texttt{xsmaddasp, xsmaddmsp, xmssubasp, xmssubmsp}
- \texttt{xsnmaddasp, xsnmaddmsp, xsnmsubasp, xsnmsubmsp}

- \texttt{xsrsp, xsrspq, xsrspsp, xsrspqsp}

- \texttt{xsrsp, xsrspq, xsrspsp, xsrspqsp}

- \texttt{xsrsp, xsrspq, xsrspsp, xsrspqsp}

Program Notes:

- In some implementations, enabling Inexact exceptions can degrade performance more than does enabling other types of floating-point exception.
do the following.

1. \texttt{XX} is set to 1.

2. The result is placed into doubleword element 0 of \texttt{VSR[XT]} in double-precision format. The contents of doubleword element 1 of \texttt{VSR[XT]} are set to 0.

3. \texttt{FPRF} is set to indicate the class and sign of the result.

For any of the following instructions,

\texttt{VSX Scalar Convert with round to zero Double-Precision to Signed Word format (xscvdpsxws)}
\texttt{VSX Scalar Convert with round to zero Double-Precision to Unsigned Word format (xscvdpuws)}

do the following.

1. \texttt{XX} is set to 1.

2. The result is placed into word element 1 of \texttt{VSR[XT]}. The contents of word elements 0, 2, and 3 of \texttt{VSR[XT]} are set to 0.

3. \texttt{FPRF} is set to indicate the class and sign of the result.

For any of the following instructions,

\texttt{VSX Scalar Quad-Precision Arithmetic instructions}
\texttt{xsaddqp[o], xsdivqp[o], xsmulqp[o], xsqrtqp[o], xssubqp[o]}
\texttt{xsmaddqp[o], xsmsubqp[o], xsnmaddqp[o], xsnmsubqp[o]}

\texttt{VSX Scalar Round to Quad-Precision Integer with Inexact (xsrqpix)}
\texttt{VSX Scalar Round Quad-Precision to Double-Extended Precision (xsrqpxp)}

do the following.

1. \texttt{XX} is set to 1.

2. The result is placed into \texttt{VSR[VRT+32]} in quad-precision format.

3. \texttt{FR} is set to indicate if the rounded result was incremented. \texttt{FI} is set to 1. \texttt{FPRF} is set to indicate the class and sign of the result.

For \texttt{VSX Scalar Convert with round Quad-Precision to Double-Precision format (xscvqdpd)}, do the following.

1. \texttt{XX} is set to 1.

2. The result is placed into doubleword element 0 of \texttt{VSR[VRT+32]} in double-precision format.

\hspace{1cm} \texttt{0x0000_0000_0000_0000} is placed into doubleword element 1 of \texttt{VSR[VRT+32]}.

3. \texttt{FR} is set to indicate if the rounded result was incremented. \texttt{FI} is set to 1. \texttt{FPRF} is set to indicate the class and sign of the result.
For **VSX Scalar truncate & Convert Quad-Precision to Signed Doubleword** (*xscvqpsdz*), do the following.

1. \( XX \) is set to 1.
2. The result is placed into doubleword element 0 of VSR[XT] in signed integer format.
   \( 0x0000_0000_0000_0000 \) is placed into doubleword element 1 of VSR[VRT+32].
3. \( FR \) is set to 0. \( FI \) is set to 1. \( FPRF \) is undefined.

For **VSX Scalar truncate & Convert Quad-Precision to Signed Word** (*xscvqpswz*), do the following.

1. \( XX \) is set to 1.
2. The result is placed into word element 1 of VSR[XT] in signed integer format.
   \( 0x0000_0000 \) is placed into word elements 0, 2, and 3 of VSR[VRT+32].
3. \( FR \) is set to 0. \( FI \) is set to 1. \( FPRF \) is undefined.

For **VSX Scalar truncate & Convert Quad-Precision to Unsigned Doubleword** (*xscvqpwdz*), do the following.

1. \( XX \) is set to 1.
2. The result is placed into doubleword element 0 of VSR[XT] in unsigned integer format.
   \( 0x0000_0000_0000_0000 \) is placed into doubleword element 1 of VSR[VRT+32].
3. \( FR \) is set to 0. \( FI \) is set to 1. \( FPRF \) is undefined.

For **VSX Scalar truncate & Convert Quad-Precision to Unsigned Word** (*xscvqpwz*), do the following.

1. \( XX \) is set to 1.
2. The result is placed into word element 1 of VSR[XT] in unsigned integer format.
   \( 0x0000_0000 \) is placed into word elements 0, 2, and 3 of VSR[VRT+32].
3. \( FR \) is set to 0. \( FI \) is set to 1. \( FPRF \) is undefined.

For **VSX Scalar Convert with round Double-Precision to Half-Precision truncate** (*xscvdphp*), do the following.

1. \( XX \) is set to 1.
2. The result is placed into the rightmost halfword of doubleword element 0 of VSR[XT] as a half-precision value.
   The contents of the leftmost 3 halfwords of doubleword element 0 of VSR[XT] are set to 0.
   The contents of doubleword element 1 of VSR[XT] are set to 0.
3. \( FR \) is set to indicate if the rounded result was incremented. \( FI \) is set to 1. \( FPRF \) is set to indicate the class and sign of the result.
For any of the following instructions,

**VSX Scalar Double-Precision Arithmetic instructions**
- `xsadddp`, `xssubdp`, `xsmuldp`, `xsdvdp`, `xssqrtdp`
- `xsmaddadp`, `xsmaddmdp`, `xsmsubadp`, `xsmsubmdp`
- `xsnmaddadp`, `xsnmaddmdp`, `xsnmsubadp`, `xsnmsubmdp`

**VSX Scalar Single-Precision Arithmetic instructions**
- `xsaddsp`, `xssubsp`, `xsmulsp`, `xsdvsp`, `xssqrtsp`
- `xsmaddasp`, `xsmaddmsp`, `xsmsubasp`, `xsmsubmsp`
- `xsnmaddasp`, `xsnmaddmsp`, `xsnmsubasp`, `xsnmsubmsp`

**VSX Scalar Reciprocal Estimate instructions**
- `xsredp`, `xsrqtedp`, `xsresp`, `xsrqresp`

**VSX Scalar Round to Single-Precision (xsrsp)**

**VSX Scalar Round to Double-Precision Integer Exact using Current rounding mode (xsrdpic)**

**VSX Scalar Convert with round Signed Doubleword to Double-Precision format (xscvsxddp)**

**VSX Scalar Convert with round Unsigned Doubleword to Double-Precision format (xscvuxddp)**

**VSX Scalar Convert with round Signed Doubleword to Single-Precision format (xscvsxdsp)**

**VSX Scalar Convert with round Unsigned Doubleword to Single-Precision format (xscvuxdsp)**

For the following:

1. `XX` is set to 1.
2. `VSR[XT]` is not modified.
3. `FR`, `FI`, and `FPRF` are not modified.

For the VSX Vector Convert with round Single-Precision to Half-Precision format (xvcvsphp) instruction, do the following.

1. `XX` is set to 1.
2. `VSR[XT]` is not modified.
3. `FR`, `FI`, and `FPRF` are not modified.
7.4.5.3 Action for XE=0

When Inexact exception is disabled (XE=0) and an Inexact exception occurs, the following actions are taken:

For VSX Scalar round and Convert Double-Precision to Single-Precision format (xscvdpsp), do the following.

1. \(XX\) is set to 1.
2. The result is placed into word elements 0 and 1 of \(VSR[XT]\) as a single-precision value. The contents of word elements 2-3 of \(VSR[XT]\) are set to 0.
3. \(FPRF\) is set to indicate the class and sign of the result.

For any of the following instructions,

<table>
<thead>
<tr>
<th>VSX Scalar Double-Precision Arithmetic instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>xsadddp, xssubdp, xsmuldp, xsdivdp, xssqrtdp</td>
</tr>
<tr>
<td>xsmaddadp, xsmaddmdp, xsmsubadp, xsmsubmdp</td>
</tr>
<tr>
<td>xsnmaddadp, xsnmaddmdp, xsnmsubadp, xsnmsubmdp</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>VSX Scalar Single-Precision Arithmetic instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>xsaddsp, xssubsp, xsmulsp, xsdivsp, xssqrtsp</td>
</tr>
<tr>
<td>xsmaddasp, xsmaddmsp, xsmsubasp, xsmsubmsp</td>
</tr>
<tr>
<td>xsnmaddasp, xsnmaddmsp, xsnmsubasp, xsnmsubmsp</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>VSX Scalar Round to Single-Precision (xsrsp)</th>
</tr>
</thead>
<tbody>
<tr>
<td>VSX Scalar Round to Double-Precision Integer Exact using Current rounding mode (xsrdpic)</td>
</tr>
<tr>
<td>VSX Scalar Convert with round Signed Doubleword to Double-Precision format (xscvsxddp)</td>
</tr>
<tr>
<td>VSX Scalar Convert with round Unsigned Doubleword to Double-Precision format (xscvuxddp)</td>
</tr>
</tbody>
</table>

do the following.

1. \(XX\) is set to 1.
2. The result is placed into doubleword element 0 of \(VSR[XT]\) as a double-precision value. The contents of doubleword element 1 of \(VSR[XT]\) are set to 0.
3. \(FPRF\) is set to indicate the class and sign of the result.

For any of the following instructions,

<table>
<thead>
<tr>
<th>VSX Scalar Convert with round to zero Double-Precision To Signed Word format (xscvdpsxws)</th>
</tr>
</thead>
<tbody>
<tr>
<td>VSX Scalar Convert with round to zero Double-Precision To Unsigned Word format (xscvdpuxws)</td>
</tr>
</tbody>
</table>

do the following.

1. \(XX\) is set to 1.
2. The result is placed into word elements 0 and 1 of \(VSR[XT]\). The contents of word elements 2 and 3 of \(VSR[XT]\) are set to 0.
3. \(FPRF\) is set to indicate the class and sign of the result.
For VSX Scalar Convert with round Quad-Precision to Double-Precision format (*xscvqpdp*), do the following.

1. **XX** is set to 1.
2. The result is placed into the rightmost halfword of doubleword element 0 of *VSR[XT]* as a half-precision value.
   - The contents of the leftmost 3 halfwords of doubleword element 0 of *VSR[XT]* are set to 0.
   - The contents of doubleword element 1 of *VSR[XT]* are set to 0.
3. **FR** is set to indicate if the rounded result was incremented. **FI** is set to 1. **FPRF** is set to indicate the class and sign of the result.

For any of the following instructions,

**VSX Vector Double-Precision Arithmetic instructions**

- *xvadddp*
- *xvsubdp*
- *xvmuldp*
- *xvdivdp*
- *xvsqrtdp*
- *xvmaddadp*
- *xvmaddmdp*
- *xvmsubadp*
- *xvmsubmdp*
- *xvnmsaddadp*
- *xvnmsaddmdp*
- *xvnmsubadp*
- *xvnmsubmdp*

do the following.

1. **XX** is set to 1.
2. For each vector element causing an Inexact exception, the result is placed into its respective doubleword element of *VSR[XT]* in double-precision format.
3. **FR**, **FI**, and **FPRF** are not modified.

For any of the following instructions,

**VSX Scalar Quad-Precision Arithmetic instructions**

- *xsaddqp[o]*
- *xsdqvoq[p]*
- *xsmulqp[o]*
- *xssqrtqp[o]*
- *xssubqp[o]*
- *xsmaddqp[o]*
- *xsmsubqp[o]*
- *xsnmaddqp[o]*
- *xsnnsubqp[o]*

**VSX Scalar Round Quad-Precision to Double-Extended-Precision (xsrqpxp)**

**VSX Scalar Round to Quad-Precision Integer with Inexact (xsrqpix)**

do the following.

1. **XX** is set to 1.
2. The result is placed into *VSR[VRT+32]* in quad-precision format.
3. **FR** is set to indicate if the rounded result was incremented. **FI** is set to 1. **FPRF** is set to indicate the class and sign of the result.

For VSX Scalar round & Convert Quad-Precision to Double-Precision (*xscvqpdp*), do the following.

1. **XX** is set to 1.
2. The result is placed into doubleword element 0 of *VSR[VRT+32]* in double-precision format.
   - `0x0000_0000_0000_0000` is placed into doubleword element 1 of *VSR[VRT+32]*.
3. **FR** is set to indicate if the rounded result was incremented. **FI** is set to 1. **FPRF** is set to indicate the class and sign of the result.
For any of the following instructions,

- **VSX Scalar truncate & Convert Quad-Precision to Signed Doubleword** (*xscvqpsdz*)
- **VSX Scalar truncate & Convert Quad-Precision to Signed Word** (*xscvqpswz*)

do the following.

1. \( \text{XX} \) is set to 1.
2. The result is placed into doubleword element 0 of \( VSR[VRT+32] \) in signed integer format.
   
   \( 0x0000_0000_0000_0000 \) is placed into doubleword element 1 of \( VSR[VRT+32] \).
3. \( FR \) is set to 0. \( FI \) is set to 1. \( FPRF \) is undefined.

For any of the following instructions,

- **VSX Scalar truncate & Convert Quad-Precision to Unsigned Doubleword** (*xscvq pudz*)
- **VSX Scalar truncate & Convert Quad-Precision to Unsigned Word** (*xscvqp uzwz*)

do the following.

1. \( \text{XX} \) is set to 1.
2. The result is placed into doubleword element 0 of \( VSR[VRT+32] \) in unsigned integer format.
   
   \( 0x0000_0000_0000_0000 \) is placed into doubleword element 1 of \( VSR[VRT+32] \).
3. \( FR \) is set to 0. \( FI \) is set to 1. \( FPRF \) is undefined.

For **VSX Vector Convert with round Single-Precision to Half-Precision format** (*xvcv spdh*), do the following.

1. \( \text{XX} \) is set to 1.
2. For each vector element causing an Underflow exception, the result is placed into the rightmost halfword of its respective word element of \( VSR[XT] \) in half-precision format.
   
   The contents of the leftmost halfword of its respective word element of \( VSR[XT] \) are set to 0.
3. \( FR, FI, \) and \( FPRF \) are not modified.

For any of the following instructions,

- **VSX Vector Single-Precision Arithmetic instructions**
  - *xvaddsp*, *xvsubsp*, *xvmulp*, *xdivsp*, *xvsqrtsp*
  - *xvmaddasp*, *xvmaddmsp*, *xvmsubasp*, *xvmsubmsp*
  - *xvnmsubasp*, *xvnmsubmsp*, *xvnmsubmsp*

do the following.

1. \( \text{XX} \) is set to 1.
2. For each vector element causing an Inexact exception, the result is placed into its respective word element of \( VSR[XT] \) in single-precision format.
3. \( FR, FI, \) and \( FPRF \) are not modified.
7.5 VSX Storage Access Operations

The VSX Storage Access instructions compute the effective address (EA) of the storage to be accessed as described in Power ISA Book I.

7.5.1 Accessing Aligned Storage Operands

The following quadword-aligned array, AH, consists of 8 halfwords.

```c
short AW[4] = { 0x0001_0203, 0x0405_0607, 0x0809_0A0B, 0x0C0D_0E0F };
```

Figure 121 illustrates the Big-Endian storage image of array AW.

![Big-Endian storage image of array AW](image1)

Figure 121.Big-Endian storage image of array AW

Figure 122 illustrates the Little-Endian storage image of array AW.

![Little-Endian storage image of array AW](image2)

Figure 122.Little-Endian storage image of array AW

Figure 123 shows the result of loading that quadword into a VSR or, equivalently, shows the contents that must be in a VSR if storing that VSR is to produce the storage contents shown in Figure 121 for Big-Endian. Note that Figure shows the effect of loading the quadword from both Big-Endian storage and Little-Endian storage.

![Vector-Scalar Register contents for aligned quadword Load or Store VSX Vector](image3)
7.5.2 Accessing Unaligned Storage Operands

The following array, B, consists of 5 word elements.

```c
int B[5];
B[0] = 0x01234567;
B[1] = 0x00112233;
B[2] = 0x44556677;
B[3] = 0x8899AABB;
B[4] = 0xCCDDEEFF;
```

Figure 124 illustrates both Big-Endian and Little-Endian storage images of array B.

Loading an Unaligned Quadword from Big-Endian Storage

Loading elements from elements 1 through 4 of B (see Figure 124) into VR[VT] involves an unaligned quadword storage access.

VSX supports word-aligned vector and scalar storage accesses using Big-Endian byte ordering.

Figure 125. Process to load unaligned quadword from Big-Endian storage using Load VSX Vector Word*4 Indexed

Loading an Unaligned Quadword from Little-Endian Storage

Loading elements from elements 1 through 4 of B (see Figure 124) into VR[VT] involves an unaligned quadword storage access.

VSX supports word-aligned vector and scalar storage accesses using Little-Endian byte ordering.

Figure 126. Process to load unaligned quadword from Little-Endian storage Load VSX Vector Word*4 Indexed
Storing an Unaligned Quadword to Big-Endian Storage

Storing a VSR to elements 1 through 4 of B (see Figure 124) into VR[VT] involves an unaligned quadword storage access.

VSX supports word-aligned vector and scalar storage accesses using Big-Endian byte ordering.

Big-Endian storage image of array B

       0x0010: FF FE FD FC

Figure 128. Process to store unaligned quadword to Little-Endian storage using Store VSX Vector Word*4 Indexed

7.5.3 Storage Access Exceptions

Storage accesses cause the system data storage error handler to be invoked if the program is not allowed to modify the target storage (Store only), or if the program attempts to access storage that is unavailable.
7.6 VSX Instruction Set

7.6.1 VSX Instruction Set Summary

7.6.1.1 VSX Storage Access Instructions

Load VSX Scalar instructions place a copy of the contents of the addressed byte, halfword, word, or doubleword in storage into the left-most doubleword element of the target VSR. For integer byte, halfword, and word forms, the data are placed into the rightmost byte, halfword, or word of the doubleword, and the leftmost bits of the doubleword are set to 0 (or set to the copy of the sign bit for \textit{xsiwax}). For the single-precision floating-point word form, the data is converted to double-precision format and placed into the doubleword. The contents of the right-most doubleword element of the target VSR are set to 0.

Store VSX Scalar instructions place a copy of the contents of the leftmost doubleword element (or portions of) in the source VSR into the addressed byte, halfword, word or doubleword in storage. For integer byte, halfword, and word forms, the rightmost byte, halfword, or word of the doubleword are stored.

Load VSX Vector instructions load a quadword from storage as a vector of 16 byte elements, 8 halfword elements, 4 word elements, 2 doubleword elements or a quadword element into a VSR.

Load VSX Vector & Splat instructions load a word or doubleword from storage and replicate the data into the 4 words or 2 doublewords of a VSR.

Store VSX Vector instructions store a vector of 16 byte elements, 8 halfword elements, 4 word elements, 2 doubleword elements or a quadword element from a VSR into a quadword in storage.

Load VSX Vector with Length instruction loads from 0 to 16 bytes into a VSR.

Store VSX Vector with Length instruction stores from 0 to 16 bytes from a VSR.

Load VSX Vector Paired instructions load an octword (32 bytes) from storage into two sequential VSRs (i.e., a vector of 32 byte elements, 16 halfword elements, 8 word elements, 4 doubleword elements or 2 quadword elements).

VSX Vector Store Paired instructions store the contents of two sequential VSRs into an octword (32 bytes) in storage (i.e., a vector of 32 byte elements, 16 halfword elements, 8 word elements, 4 doubleword elements or 2 quadword elements).

7.6.2 VSX Instruction Description Conventions

7.6.2.1 VSX Instruction RTL Operators

\( x.\text{bit}[y] \)  
Return the contents of bit \( y \) of \( x \).

\( x.\text{bit}[y:z] \)  
Return the contents of bits \( y:z \) of \( x \).

\( x.\text{word}[y] \)  
Return the contents of word element \( y \) of \( x \).

\( x.\text{word}[y:z] \)  
Return the contents of word elements \( y:z \) of \( x \).

\( x.\text{dword}[y] \)  
Return the contents of doubleword element \( y \) of \( x \).

\( x.\text{dword}[y:z] \)  
Return the contents of doubleword elements \( y:z \) of \( x \).

\( x = y \)  
The value of \( y \) is placed into \( x \).

\( x \|\| y \)  
The value of \( y \) is ORed with the value \( x \) and placed into \( x \).

\( \neg x \)  
Return the one's complement of \( x \).

\( !x \)  
Return 1 if the contents of \( x \) are equal to 0, otherwise return 0.

\( x \|\| y \)  
Return the value of \( x \) concatenated with the value of \( y \). For example, \( 0b010 \|\| 0b111 \) is the same as \( 0b010111 \).

\( x ^ y \)  
Return the value of \( x \) exclusive ORed with the value of \( y \).

\( x ? y : z \)  
If the value of \( x \) is true, return the value of \( y \), otherwise return the value \( z \).

\( x+y \)  
\( x \) and \( y \) are integer values.

Return the sum of \( x \) and \( y \).
7.6.2.2 VSX Instruction RTL Function Calls

**bfloat16\_CONVERT\_FROM\_BFP(x)**

- x is a floating-point value represented in the working format.
  - If \(x\) is SNaN or QNaN, do the following.
    - Bit 0 of result is set to the value of \(x\) sign.
    - Bits 1:8 of result are set to the value 0b1111111.
    - Bits 9:15 of result are set to the value of bits 1:8 of \(x\) significand.
  - Otherwise, if \(x\) is an infinity, do the following.
    - Bit 0 of result is set to the value of \(x\) sign.
    - Bits 1:8 of result are set to the value 0b1111111.
    - Bits 9:15 of result are set to 0.
  - Otherwise, if \(x\) is a zero, do the following.
    - Bit 0 of result is set to the value of \(x\) sign.
    - Bits 9:15 of result are set to 0.
  - Otherwise, if \(x\) exponent is less than -126, do the following.
    - Bit 0 of result is set to the value of \(x\) sign.
    - \(sh\_cnt\) is set to the difference, -126 - \(x\) exponent.
    - Bits 1:8 of result are set to 0b00000000.
    - Bits 9:15 of result are set to bits 1:8 of \(x\) significand shifted right by \(sh\_cnt\) bits.
  - Otherwise, do the following.
    - Bit 0 of result is set to the value of \(x\) sign.
    - Bits 1:8 of result are set to the sum, \(x\) exponent + 127.
    - Bits 9:15 of result are set to bits 1:8 of \(x\) significand.

Return result (bfloat16 format).

**bfp\_ABSOLUTE(x)**

- x is a binary floating-point value represented in the binary floating-point working format.

Return x with sign set to 0.

**bfp\_ADD(x, y)**

- x is a binary floating-point value represented in the binary floating-point working format.
- y is a binary floating-point value represented in the binary floating-point working format.

- If \(x\) or \(y\) is an SNaN, \(vxsnan\_flag\) is set to 1.
- If \(x\) is an infinity and \(y\) is an infinity of the opposite sign, \(vxisi\_flag\) is set to 1.
- If \(x\) is a QNaN, return \(x\).
- Otherwise, if \(x\) is an SNaN, return \(x\) represented as a QNaN.
- Otherwise, if \(y\) is a QNaN, return \(y\).
- Otherwise, if \(y\) is an SNaN, return \(y\) represented as a QNaN.
- Otherwise, if \(x\) and \(y\) are infinities of opposite sign, return the standard QNaN.
- Otherwise, return the normalized sum of \(x\) and \(y\), having unbounded range and precision.

**bfp\_COMPARE\_EQ(x, y)**

- x is a binary floating-point value represented in the binary floating-point working format.
- y is a binary floating-point value represented in the binary floating-point working format.

- Return 0b00 if \(x\) is NaN or \(y\) is a NaN.
- Otherwise, return 0b1 if \(x\) is a Zero and \(y\) is a Zero.
- Otherwise, return 0b1 if \(x\) is equal to \(y\).
- Otherwise, return 0b0.
**bfp_COMPARE_GT(x, y)**

- x is a binary floating-point value represented in the binary floating-point working format.
- y is a binary floating-point value represented in the binary floating-point working format.

Return $0b0$ if x is NaN or y is a NaN.
Otherwise, return $0b0$ if x is a Zero and y is a Zero.
Otherwise, return $0b1$ if x is greater than y.
Otherwise, return $0b0$.

**bfp_COMPARE_LT(x, y)**

- x is a binary floating-point value represented in the binary floating-point working format.
- y is a binary floating-point value represented in the binary floating-point working format.

Return $0b0$ if x is NaN or y is a NaN.
Otherwise, return $0b0$ if x is a Zero and y is a Zero.
Otherwise, return $0b1$ if x is less than y.
Otherwise, return $0b0$.

**bfp_CONVERT_FROM_BFLOAT16(x)**

- x is a floating-point value represented in bfloat16 format.

Let sign be the contents of bit 0 of x.
Let exponent be the contents of bits 1:8 of x.
Let fraction be the contents of bits 9:15 of x.

Let result.sign be set to 0.
Let result.exponent be set to 0.
Let result.significand be set to 0.
Let result.class.SNaN be set to 0.
Let result.class.QNaN be set to 0.
Let result.class.Infinity be set to 0.
Let result.class.Zero be set to 0.
Let result.class.Denormal be set to 0.
Let result.class.Normal be set to 0.

If x is an SNaN, do the following.
- result.class.SNaN is set to 1.
- result.sign is set to the value of sign.
- The contents of result.significand are set to 0.
- The contents of bits 1:8 of result.significand are set to the value of fraction.

Otherwise, if x is a QNaN, do the following.
- result.class.QNaN is set to 1.
- result.sign is set to the value of sign.
- The contents of result.significand are set to 0.
- The contents of bits 1:8 of result.significand are set to the value of fraction.

Otherwise, if x is an Infinity value, do the following.
- result.class.Infinity is set to 1.
- result.sign is set to the value of sign.

Otherwise, if x is a Zero value, do the following.
- result.class.Zero is set to 1.
- result.sign is set to the value of sign.

Otherwise, if x is a Denormal value, do the following.
- result.class.Denormal is set to 1.
- result.sign is set to the value of sign.
result.exponent is set to the value -126.

The contents of bits 1:8 of result.significand are set to the value of fraction.

result.significand is shifted left until the contents bit 0 of result.significand are equal to 1.
result.exponent is decremented by the number of bits result.significand was shifted.

Otherwise, do the following.
result.class.Normal is set to 1.
result.sign is set to the value of sign.
result.exponent is set to the value of exponent subtracted by 127.

The contents of bit 0 of result.significand are set to 1.
The contents of bits 1:8 of result.significand are set to the value of fraction.

Return result (binary floating-point working format).

bfp_CONVERT_FROM_BFP16(x)

x is a floating-point value represented in half-precision format.

Let exponent be the contents of bits 1:5 of x.
Let fraction be the contents of bits 6:15 of x.

Let result.sign be set to 0.
Let result.exponent be set to 0.
Let result.significand be set to 0.
Let result.class.SNaN be set to 0.
Let result.class.QNaN be set to 0.
Let result.class.Infinity be set to 0.
Let result.class.Zero be set to 0.
Let result.class.Denormal be set to 0.
Let result.class.Normal be set to 0.

If x is a SNaN, do the following.
result.class.SNaN is set to 1.
result.sign is set to the contents of bit 0 of x.

The contents of bit 0 of result.significand are set to 0.
The contents of bits 1:10 of result.significand are set to the value of fraction.

Otherwise, if x is a QNaN, do the following.
result.class.QNaN is set to 1.
result.sign is set to the contents of bit 0 of x.

The contents of bit 0 of result.significand are set to 0.
The contents of bits 1:10 of result.significand are set to the value of fraction.

Otherwise, if x is an Infinity value, do the following.
result.class.Infinity is set to 1.
result.sign is set to the contents of bit 0 of x.

Otherwise, if x is a Zero value, do the following.
result.class.Zero is set to 1.
result.sign is set to the contents of bit 0 of x.

Otherwise, if x is a Denormal value, do the following.
result.class.Denormal is set to 1.
result.sign is set to the contents of bit 0 of x.
result.exp is set to the value -14.
The contents of bit 0 of \texttt{result.significand} are set to 0.
The contents of bits 1:10 of \texttt{result.significand} are set to the value of \texttt{fraction}.
\texttt{result.significand} is shifted left until the contents bit 0 of \texttt{result.significand} are equal to 1.
\texttt{result.exponent} is decremented by the the number of bits \texttt{result.significand} was shifted.

Otherwise, do the following.
\texttt{result.class.Normal} is set to 1.
\texttt{result.sign} is set to the contents of bit 0 of \texttt{x}.
\texttt{result.exp} is set to the value of \texttt{exponent} subtracted by 15.

The contents of bit 0 of \texttt{result.significand} are set to 1.
The contents of bits 1:10 of \texttt{result.significand} are set to the value of \texttt{fraction}.

Return \texttt{result}.

\texttt{bfp\_CONVERT\_FROM\_BFP32(x)}
\texttt{x} is a floating-point value represented in single-precision format.

Let \texttt{exponent} be the contents of bits 1:8 of \texttt{x}.
Let \texttt{fraction} be the contents of bits 9:31 of \texttt{x}.

Let \texttt{result.sign} be initialized to 0.
Let \texttt{result.exponent} be initialized to 0.
Let \texttt{result.significand} be initialized to 0.
Let \texttt{result.class.SNaN} be initialized to 0.
Let \texttt{result.class.QNaN} be initialized to 0.
Let \texttt{result.class.Infinity} be initialized to 0.
Let \texttt{result.class.Zero} be initialized to 0.
Let \texttt{result.class.Denormal} be initialized to 0.
Let \texttt{result.class.Normal} be initialized to 0.

If \texttt{x} is a SNaN, do the following.
\texttt{result.class.SNaN} is set to 1.
\texttt{result.sign} is set to the contents of bit 0 of \texttt{x}.

The contents of bit 0 of \texttt{result.significand} are set to 0.
The contents of bits 1:23 of \texttt{result.significand} are set to the value of \texttt{fraction}.

Otherwise, if \texttt{x} is a QNaN, do the following.
\texttt{result.class.QNaN} is set to 1.
\texttt{result.sign} is set to the contents of bit 0 of \texttt{x}.

The contents of bit 0 of \texttt{result.significand} are set to 0.
The contents of bits 1:23 of \texttt{result.significand} are set to the value of \texttt{fraction}.

Otherwise, if \texttt{x} is an Infinity value, do the following.
\texttt{result.class.Infinity} is set to 1.
\texttt{result.sign} is set to the contents of bit 0 of \texttt{x}.

Otherwise, if \texttt{x} is a Zero value, do the following.
\texttt{result.class.Zero} is set to 1.
\texttt{result.sign} is set to the contents of bit 0 of \texttt{x}.

Otherwise, if \texttt{x} is a Denormal value, do the following.
\texttt{result.class.Denormal} is set to 1.
\texttt{result.sign} is set to the contents of bit 0 of \texttt{x}.
\texttt{result.exponent} is set to the value -126.

The contents of bit 0 of \texttt{result.significand} are set to 0.
The contents of bits 1:23 of result.significand are set to the value of fraction.

result.significand is shifted left until the contents bit 0 of result.significand are equal to 1. Result.exponent is decremented by the the number of bits result.significand was shifted.

Otherwise, do the following.
result.class.Normal is set to 1.
result.sign is set to the contents of bit 0 of x.
result.exponent is set to the value of exponent subtracted by 127.

The contents of bit 0 of result.significand are set to 1.
The contents of bits 1:23 of result.significand are set to the value of fraction.

Return result.

bfp_CONVERT_FROM_BFP64(x)

x is a binary floating-point value represented in double-precision format.

Let exponent be the contents of bits 1:11 of x.
Let fraction be the contents of bits 12:63 of x.

result.sign is initialized to 0.
result.exponent is initialized to 0.
result.significand is initialized to 0.
result.class.SNaN is initialized to 0.
result.class.QNaN is initialized to 0.
result.class.Infinity is initialized to 0.
result.class.Zero is initialized to 0.
result.class.Denormal is initialized to 0.
result.class.Normal is initialized to 0.

If x is a SNaN, do the following.
result.class.SNaN is set to 1.
result.sign is set to the contents of bit 0 of x.
The contents of bit 0 of result.significand are set to 0.
The contents of bits 1:52 of result.significand are set to the value of fraction.
The contents of the rest of result.significand are set to 0.

Otherwise, if x is a QNaN, do the following.
result.class.QNaN is set to 1.
result.sign is set to the contents of bit 0 of x.
The contents of bit 0 of result.significand are set to 0.
The contents of bits 1:52 of result.significand are set to the value of fraction.
The contents of the rest of result.significand are set to 0.

Otherwise, if x is an Infinity, do the following.
result.class.Infinity is set to 1.
result.sign is set to the contents of bit 0 of x.

Otherwise, if x is a Zero, do the following.
result.class.Zero is set to 1.
result.sign is set to the contents of bit 0 of x.

Otherwise, if x is a Denormal, do the following.
result.class.Denormal is set to 1.
result.sign is set to the contents of bit 0 of x.
result.exp is set to the value -1022.
The contents of bit 0 of result.significand are set to 0.
The contents of bits 1:52 of result.significand are set to the value of fraction.
The contents of the rest of result.significand are set to 0.
result.significand is shifted left until the contents bit 0 of result.significand are equal to 1.
result.exponent is decremented by the the number of bits result.significand was shifted.

Otherwise, do the following.
result.class.Normal is set to 1.
result.sign is set to the contents of bit 0 of x.
result.exp is set to the value of exponent subtracted by 1023.
The contents of bit 0 of result.significand are set to 1.
The contents of bits 1:52 of result.significand are set to the value of fraction.
The contents of the rest of result.significand are set to 0.

Return result (i.e., the value x in the binary floating-point working format).

bfp_CONVERT_FROM_BFP128(x)
x is a binary floating-point value represented in quad-precision format.

Let exponent be the contents of bits 1:15 of x.
Let fraction be the contents of bits 16:127 of x.

result.sign is initialized to 0.
result.exponent is initialized to 0.
result.significand is initialized to 0.
result.class.SNaN is initialized to 0.
result.class.QNaN is initialized to 0.
result.class.Infinity is initialized to 0.
result.class.Zero is initialized to 0.
result.class.Denormal is initialized to 0.
result.class.Normal is initialized to 0.

If x is a SNaN, do the following.
result.class.SNaN is set to 1.
result.sign is set to the contents of bit 0 of x.
The contents of bit 0 of result.significand are set to 0.
The contents of bits 1:112 of result.significand are set to the value of fraction.
The contents of the rest of result.significand are set to 0.

Otherwise, if x is a QNaN, do the following.
result.class.QNaN is set to 1.
result.sign is set to the contents of bit 0 of x.
The contents of bit 0 of result.significand are set to 0.
The contents of bits 1:112 of result.significand are set to the value of fraction.
The contents of the rest of result.significand are set to 0.

Otherwise, if x is an Infinity, do the following.
result.class.Infinity is set to 1.
result.sign is set to the contents of bit 0 of x.

Otherwise, if x is a Zero, do the following.
result.class.Zero is set to 1.
result.sign is set to the contents of bit 0 of x.

Otherwise, if x is a Denormal, do the following.
result.class.Denormal is set to 1.
result.sign is set to the contents of bit 0 of x.
result.exp is set to the value -16382.
The contents of bit 0 of result.significand are set to 0.
The contents of bits 1:112 of result.significand are set to the value of fraction.
The contents of the rest of result.significand are set to 0.
result.significand is shifted left until the contents bit 0 of result.significand are equal to 1.
result.exponent is decremented by the number of bits result.significand was shifted.

Otherwise, do the following.
result.class.Normal is set to 1.
result.sign is set to the contents of bit 0 of x.
result.exp is set to the value of exponent subtracted by 16383.
The contents of bit 0 of result.significand are set to 1.
The contents of bits 1:112 of result.significand are set to the value of fraction.
The contents of the rest of result.significand are set to 0.

Return result (i.e., the value x in the binary floating-point working format).

bfp_CONVERT_FROM_SI64(x)
x is an integer value represented in signed doubleword integer format.

result.sign is initialized to 0.
result.exponent is initialized to 0.
result.significand is initialized to 0.
result.class.SNaN is initialized to 0.
result.class.QNaN is initialized to 0.
result.class.Infinity is initialized to 0.
result.class.Zero is initialized to 0.
result.class.Denormal is initialized to 0.
result.class.Normal is initialized to 0.

If x is equal to 0x0000_0000_0000_0000, result.class.Zero is set to 1.

Otherwise, do the following.
result.class.Normal is set to 1.
result.sign is set to the contents of bit 0 of x.
result.exponent is set to the value 64.
Bits 0:64 of result.significand are set to the value of x sign-extended to 65 bits.

If bit 0 of result.significand is equal to 1, result.sign is set to 1, and result.significand is set to the value of the two's complement of result.significand.

If bit 0 of result.significand is equal to 0, result.significand is shifted left until bit 0 of result.significand is equal to 1, and result.exponent is decremented by the number of bits result.significand is shifted.

Return result (i.e., the value x in the binary floating-point working format).

bfp_CONVERT_FROM_SI128(x)
x is a 128-bit signed integer value.

result.sign is initialized to 0.
result.exponent is initialized to 0.
result.significand is initialized to 0.
result.class.SNaN is initialized to 0.
result.class.QNaN is initialized to 0.
result.class.Infinity is initialized to 0.
result.class.Zero is initialized to 0.
result.class.Denormal is initialized to 0.
result.class.Normal is initialized to 0.

If x is equal to 0x0000_0000_0000_0000_0000_0000_0000_0000,
result.class.Zero is set to 1.

Otherwise, do the following.
result.class.Normal is set to 1.
result.sign is set to the contents of bit 0 of \(x\).
result.exponent is set to the value 128.
Bits 0:128 of result.significand are set to the value of \(x\) sign-extended to 129 bits.

If bit 0 of result.significand is equal to 1,
result.sign is set to 1, and
result.significand is set to the value of the two’s complement of result.significand.

If bit 0 of result.significand is equal to 0,
result.significand is shifted left until bit 0 of result.significand is equal to 1, and
result.exponent is decremented by the number of bits result.significand is shifted.

Return result (i.e., the value \(x\) in the binary floating-point working format).

\textbf{bfp\_CONVERT\_FROM\_UI64}(x)

\(x\) is an integer value represented in unsigned doubleword integer format.

Return \(x\) in the binary floating-point working format.

result.sign is initialized to 0.
result.exponent is initialized to 0.
result.significand is initialized to 0.
result.class.SNaN is initialized to 0.
result.class.QNaN is initialized to 0.
result.class.Infinity is initialized to 0.
result.class.Zero is initialized to 0.
result.class.Denormal is initialized to 0.
result.class.Normal is initialized to 0.

If \(x\) is equal to 0x0000_0000_0000_0000, do the following.
result.class.Zero is set to 1.

Otherwise, do the following.
result.class.Normal is set to 1.
result.sign is set to 0.
result.exponent is set to the value 64.
Bits 0:64 of result.significand is set to the value of \(x\) zero-extended to 65 bits.

If bit 0 of result.significand is equal to 0, result.significand is shifted left until bit 0 of result.significand is equal to 1 and result.exponent is decremented by the number of bits result.significand is shifted.

Return result (i.e., the value \(x\) in the binary floating-point working format).

\textbf{bfp\_CONVERT\_FROM\_UI128}(x)

\(x\) is a 128-bit unsigned integer value.

result.sign is initialized to 0.
result.exponent is initialized to 0.
result.significand is initialized to 0.
result.class.SNaN is initialized to 0.
result.class.QNaN is initialized to 0.
result.class.Infinity is initialized to 0.
result.class.Zero is initialized to 0.
result.class.Denormal is initialized to 0.
result.class.Normal is initialized to 0.

If \( x \) is equal to 0x0000_0000_0000_0000_0000_0000_0000_0000, do the following.
result.class.Zero is set to 1.

Otherwise, do the following.
result.class.Normal is set to 1.
result.sign is set to 0.
result.exponent is set to the value 128.
Bits 0:128 of result.significand are set to the value of \( x \) zero-extended to 129 bits.

If bit 0 of result.significand is equal to 0,
result.significand is shifted left until bit 0 of result.significand is equal to 1 and result.exponent is decremented by the number of bits result.significand is shifted.

Return result (i.e., the value \( x \) in the binary floating-point working format).

\[ \text{bfp\_DENORM}(x, y) \]
\( x \) is an integer value specifying the target format’s \( \text{Emin} \) value.
y is a binary floating-point value that is represented in the binary floating-point working format.

If \( y \).exponent is less than \( \text{Emin} \), let \( \text{sh\_cnt} \) be the value \( \text{Emin} - y \).exponent.
Otherwise, let \( \text{sh\_cnt} \) be the value 0.

\( y \).significand, having unbounded precision, is shifted right by \( \text{sh\_cnt} \) bits.
\( y \).exponent is incremented by \( \text{sh\_cnt} \).

Return \( y \) in the binary floating-point working format.

\[ \text{bfp\_DIVIDE}(x, y) \]
\( x \) is a binary floating-point value that is represented in the binary floating-point working format.
y is a binary floating-point value that is represented in the binary floating-point working format.

If \( x \) or \( y \) is an SNaN, \( \text{vxsnan\_flag} \) is set to 1.
Otherwise, if \( x \) and \( y \) are infinities, \( \text{vxidi\_flag} \) is set to 1.
Otherwise, if \( x \) and \( y \) are zeros, \( \text{vxzdz\_flag} \) is set to 1.
Otherwise, if \( x \) is a finite value and \( y \) is a zero, \( \text{zx\_flag} \) is set to 1.

If \( x \) is a QNaN, return \( x \).
Otherwise, if \( x \) is an SNaN, return \( x \) represented as a QNaN.
Otherwise, if \( y \) is a QNaN, return \( y \).
Otherwise, if \( y \) is an SNaN, return \( y \) represented as a QNaN.
Otherwise, if \( x \) and \( y \) are infinities, return the standard QNaN.
Otherwise, if \( x \) and \( y \) are zeros, return the standard QNaN.
Otherwise, if \( y \) is a zero, return infinity, having the sign of the exclusive-OR of the signs of \( x \) and \( y \).
Otherwise, return the normalized quotient of \( x \div y \), having unbounded range and precision.

\[ \text{bfp\_INFINITY} \]
The value +Infinity represented in the binary floating-point working format.

\[ \text{bfp\_INITIALIZE}(x) \]
Let \( x \).sign be set to 0.
Let \( x \).exponent be set to 0.
Let \( x \).significand be set to 0.
Let \( x \).class.SNaN be set to 0.
Let \( x \).class.QNaN be set to 0.
Let \( x \).class.Infinity be set to 0.
Let \( x \).class.Zero be set to 0.
Let \( x \).class.Denormal be set to 0.
Let $x\_c\_lass\_Normal$ be set to 0.

Return $x$.

$\textbf{bfp\_MULTIPLY}(x, y)$

$x$ is a binary floating-point value represented in the binary floating-point working format.
y is a binary floating-point value represented in the binary floating-point working format.

If $x$ or $y$ is an SNaN, $vx\_snan\_flag$ is set to 1.
Otherwise, if $x$ is an infinity and $y$ is a zero, $vx\_imz\_flag$ is set to 1.
Otherwise, if $x$ is a zero and $y$ is an infinity, $vx\_imz\_flag$ is set to 1.

If $x$ is a QNaN, return $x$.
Otherwise, if $x$ is an SNaN, return $x$ represented as a QNaN.
Otherwise, if $y$ is a QNaN, return $y$.
Otherwise, if $y$ is an SNaN, return $y$ represented as a QNaN.
Otherwise, if $x$ is an infinity and $y$ is a zero, return the standard QNaN.
Otherwise, if $x$ is a zero and $y$ is an infinity, return the standard QNaN.
Otherwise, return the normalized product of $x \times y$, having unbounded range and precision.

$\textbf{bfp\_MULTIPLY\_ADD}(x, y, z)$

$x$ is a binary floating-point value represented in the binary floating-point working format.
y is a binary floating-point value represented in the binary floating-point working format.
z is a binary floating-point value represented in the binary floating-point working format.

If $x$, $y$, or $z$ is an SNaN, $vx\_snan\_flag$ is set to 1.
Otherwise, if $x$ is an infinity and $y$ is a zero, $vx\_imz\_flag$ is set to 1.
Otherwise, if $x$ is a zero and $y$ is an infinity, $vx\_imz\_flag$ is set to 1.

Otherwise, if $z$ and the product of $x \times y$ are Infinity values having opposite signs, $vx\_isi\_flag$ is set to 1.

If $x$ is a QNaN, return $x$.
Otherwise, if $x$ is an SNaN, return $x$ represented as a QNaN.
Otherwise, if $z$ is a QNaN, return $z$.
Otherwise, if $z$ is an SNaN, return $z$ represented as a QNaN.
Otherwise, if $x$ is an infinity and $y$ is a zero, return the standard QNaN.
Otherwise, if $x$ is a zero and $y$ is an infinity, return the standard QNaN.
Otherwise, if $z$ and the product of $x \times y$ are Infinity values having opposite signs, return the standard QNaN.
Otherwise, return the sum of $z$ and the normalized product of $x \times y$, having unbounded range and precision.

$\textbf{bfp\_NEGATE}(x)$

$x$ is a binary floating-point value that is represented in the binary floating-point working format.

If $x$ is not a NaN, return $x$ with its sign complemented. Otherwise, return $x$.

$\textbf{bfp\_NMAX\_BFLOAT16}$

Return the largest positive normalized bfloat16 floating-point value (i.e., $2^{128}.2^{128-1}$) represented in the binary floating-point working format.

return bfp\_CONVERT\_FROM\_BFLOAT16(0x7F7F)

$\textbf{bfp\_NMAX\_BFLOAT16}$

Return the largest positive normalized half-precision floating-point value (i.e., $2^{16}.2^{16-11}$), represented in the binary floating-point working format.

return bfp\_CONVERT\_FROM\_BFLOAT16(0x7BFF)
bfp_NMAX_BFP64
Return the largest finite double-precision floating-point value (i.e., $2^{1024-53}$) in the binary floating-point working format.

return bfp_CONVERT_FROM_BFP64(0x7FEF_FFFF_FFFF_FFFF)

bfp_NMAX_BFP80
Return the largest finite double-extended-precision floating-point value (i.e., $2^{16384-65}$) in the binary floating-point working format.

return bfp_CONVERT_FROM_BFP80(0x7FFE_FFFF_FFFF_FFFF_FFFF)

bfp_NMAX_BFP128
Return the largest finite quad-precision value (i.e., $2^{16384-113}$) in the binary floating-point working format.

return bfp_CONVERT_FROM_BFP128(0x7FFE_FFFF_FFFF_FFFF_FFFF_FFFF_FFFF_FFFF)

bfp_NMIN_BFLOAT16
Return the smallest positive normalized bfloat16 floating-point value (i.e., $2^{-126}$), represented in the binary floating-point working format.

return bfp_CONVERT_FROM_BFLOAT16(0x0080)

bfp_NMIN_BFP16
Return the smallest positive normalized half-precision floating-point value, $2^{-14}$, represented in the binary floating-point working format.

return bfp_CONVERT_FROM_BFP16(0x0400)

bfp_NMIN_BFP64
Return the smallest positive normalized double-precision floating-point value, $2^{-1022}$, represented in the binary floating-point working format.

return bfp_CONVERT_FROM_BFP64(0x0010_0000_0000_0000)

bfp_NMIN_BFP80
Return the smallest positive normalized double-extended-precision floating-point value, $2^{-16382}$, represented in the binary floating-point working format.

return bfp_CONVERT_FROM_BFP80(0x0001_0000_0000_0000_0000)

bfp_NMIN_BFP128
Return the smallest, positive, normalized quad-precision floating-point value, $2^{-16382}$, represented in the binary floating-point working format.

return bfp_CONVERT_FROM_BFP128(0x0001_0000_0000_0000_0000_0000_0000_0000)

bfp_QUIET(x)
\(x\) is a Signalling NaN.

Return \(x\) converted to a Quiet NaN with \(x.class.QNaN\) set to 1 and \(x.class.SNaN\) set to 0.

bfp_ROUND_CEIL(p, x)
\(x\) is a binary floating-point value that is represented in the binary floating-point working format and has unbounded exponent range and significand precision. \(x\) must be rounded as presented, without prenormalization.

\(p\) is an integer value specifying the precision (i.e., number of bits) the significand is rounded to.

Return the smallest floating-point number having unbounded exponent range and a significand with a width of \(p\) bits that is greater or equal in value to \(x\).
inc_flag is set to 1 if the magnitude of the value returned is greater than \( x \).
xx_flag is set to 1 if the value returned is not equal to \( x \).

**bfp_ROUND_FLOOR(p, x)**

\( x \) is a binary floating-point value that is represented in the binary floating-point working format and has unbounded exponent range and significand precision. The value must be rounded as presented, without prenormalization.

\( p \) is an integer value specifying the precision (i.e., number of bits) the significand is rounded to.

Return the largest floating-point number having unbounded exponent range and a significand with a width of \( p \) bits that is lesser or equal in value to \( x \).

inc_flag is set to 1 if the magnitude of the value returned is greater than \( x \).
xx_flag is set to 1 if the value returned is not equal to \( x \).

**bfp_ROUND_TO_BFLOAT16_NO_TRAP(x)**

\( x \) is a normalized binary floating-point value that is represented in the binary floating-point working format and has unbounded exponent range and significand precision.

Return the value \( x \), rounded to bfloat16 significand precision and exponent range under control of the rounding mode specified in RN, and represented in the binary floating-point working format.

With respect to this rounding function, OE and UE are ignored (treated as if OE=0 and UE=0).

```
rmode ← FPSCR.RN
if x.class.SNaN then do
  vxsnan_flag ← 1
  return bfp_QUIET(x)
end
if x.class.QNaN then return x
if x.class.Infinity then return x
if x.class.Zero then return x
if bfp_ABSOLUTE(x)<bfp_NMIN_BFLOAT16 then do
  x ← bfp_DENORM(-126,x)
  if rmode=0b00 then r ← bfp_ROUND_NEAR_EVEN(8,x)
  if rmode=0b01 then r ← bfp_ROUND_TRUNC(8,x)
  if rmode=0b10 then r ← bfp_ROUND_CEIL(8,x)
  if rmode=0b11 then r ← bfp_ROUND_FLOOR(8,x)
  ux_flag ← xx_flag
  return r
end
if rmode=0b00 then r ← bfp_ROUND_NEAR_EVEN(8,x)
if rmode=0b01 then r ← bfp_ROUND_TRUNC(8,x)
if rmode=0b10 then r ← bfp_ROUND_CEIL(8,x)
if rmode=0b11 then r ← bfp_ROUND_FLOOR(8,x)
if bfp_ABSOLUTE(r)>bfp_NMAX_BFLOAT16 then do
  if rmode=0b00 then r ← x.sign ? bfp_INFINITY : bfp_INFINITY
  if rmode=0b01 then r ← x.sign ? bfp_NMAX_BFLOAT16 : bfp_NMAX_BFLOAT16
  if rmode=0b10 then r ← x.sign ? bfp_NMAX_BFLOAT16 : bfp_INFINITY
  if rmode=0b11 then r ← x.sign ? bfp_INFINITY : bfp_NMAX_BFLOAT16
```
r.sign ← x.sign

ox_flag ← 0b1
xx_flag ← 0b1
inf_flag ← 0bU
end

return r

\texttt{bfp\_ROUND\_TO\_BFP16}(x, y)

\(y\) is a normalized floating-point value represented in the binary floating-point working format, having unbounded exponent range and significand precision.

\(x\) is a 2-bit integer value specifying one of four rounding modes.

0b00 Round to Nearest Even
0b01 Round towards Zero
0b10 Round towards +Infinity
0b11 Round towards -Infinity

If \(y\) is an QNaN, Infinity, or Zero, return \(y\). Otherwise, if \(y\) is an SNaN, set \(\text{vxsnan\_flag}\) to 1 and return the corresponding QNaN representation of \(y\). Otherwise, return the value \(y\) rounded to half-precision format's exponent range and significand precision using the rounding mode specified by \(x\).

if \text{y.class.Zero} \text{ or } \text{y.class.Infinity} \text{ then return}(y)

\text{bfp\_ROUND\_TO\_BFP16\_CEIL}(x)

$x$ is a normalized floating-point value represented in the binary floating-point working format, having unbounded exponent range and significand precision.

Return the smallest floating-point number having unbounded exponent range but half-precision significand precision that is greater or equal in value to $x$.

If the magnitude of the value returned is greater than $x$, inc\_flag is set to 1.

If the value returned is not equal to $x$, xx\_flag is set to 1.

\text{bfp\_ROUND\_TO\_BFP16\_FLOOR}(x)

$x$ is a normalized floating-point value represented in the binary floating-point working format, having unbounded exponent range and significand precision.

Return the largest floating-point number having unbounded exponent range but half-precision significand precision that is lesser or equal in value to $x$.

If the magnitude of the value returned is greater than $x$, inc\_flag is set to 1.

If the value returned is not equal to $x$, xx\_flag is set to 1.

\text{bfp\_ROUND\_TO\_BFP16\_NEAR\_EVEN}(x)

$x$ is a normalized floating-point value represented in the binary floating-point working format, having unbounded exponent range and significand precision.

Return the floating-point number having unbounded exponent range but half-precision significand precision that is nearest in value to $x$ (in case of a tie, the floating-point number having unbounded exponent range but half-precision significand precision with the least-significant bit equal to 0 is used).

If the magnitude of the value returned is greater than $x$, inc\_flag is set to 1.

If the value returned is not equal to $x$, xx\_flag is set to 1.

\text{bfp\_ROUND\_TO\_BFP16\_TRUNC}(x)

$x$ is a normalized floating-point value represented in the binary floating-point working format, having unbounded exponent range and significand precision.
Return the largest floating-point number having unbounded exponent range but half-precision significand precision that is lesser or equal in value to $x$ if $x > 0$, or the smallest floating-point number having unbounded exponent range but half-p-precision significand precision that is greater or equal in value to $x$ if $x < 0$.

If the magnitude of the value returned is greater than $x$, `inc_flag` is set to 1.

If the value returned is not equal to $x$, `xx_flag` is set to 1.

```plaintext
bfp_ROUND_TO_BFP32_SIGNIFICAND(x)
```

$x$ is a normalized binary floating-point value that is represented in the binary floating-point working format and has unbounded exponent range and significand precision.

Return the value $x$ rounded to 24-bit significand precision under control of the rounding mode specified in $RN$, retaining unbounded exponent range, represented in the binary floating-point working format.

```plaintext
rmode ← FPSCR.RN

return r  (binary floating-point working format)
return the largest double-precision floating-point integer value that is lesser or equal in value to $x$ if $x>0$, or the smallest double-precision floating-point integer value that is greater or equal in value to $x$ if $x<0$.

- If $rmode=0b010$ (Round towards $+\infty$), return the smallest double-precision floating-point integer value that is greater or equal in value to $x$.
- If $rmode=0b011$ (Round towards $-\infty$), return the largest double-precision floating-point integer value that is lesser or equal in value to $x$.
- If $rmode=0b100$ (Round to Nearest Away), return the double-precision floating-point integer value that is nearest in value to $x$ (in case of a tie, the double-precision floating-point integer value that is furthest away from 0 is used).

`inc_flag` is set to 1 if the magnitude of the value returned is greater than $x$.
`xx_flag` is set to 1 if the value returned is not equal to $x$.

**bfp_ROUND_ODD(p, x)**

$x$ is a binary floating-point value that is represented in the binary floating-point working format and has unbounded exponent range and significand precision. $x$ must be rounded as presented, without prenormalization.

$p$ is an integer value specifying the precision (i.e., number of bits) the significand is rounded to.

Return $x$ with bit $p-1$ of the significand set to 1 if any of the bits to the right of bit $p-1$ of the significand of $x$ are equal to 1, and all bits to the right of bit $p-1$ of the significand of the value returned are set to 0. Otherwise return $x$ with all bits to the right of bit $p-1$ of the significand set to 0.

`inc_flag` is set to 1 if the magnitude of the value returned is greater than $x$.
`xx_flag` is set to 1 if the value returned is not equal to $x$.

**bfp_ROUND_NEAR_EVEN(p, x)**

$x$ is a binary floating-point value that is represented in the binary floating-point working format and has unbounded exponent range and significand precision. $x$ must be rounded as presented, without prenormalization.

$p$ is an integer value specifying the precision (i.e., number of bits) the significand is rounded to.

Return the floating-point number having unbounded exponent range and a significand with a width of $p$ bits that is nearest in value to $x$ (in case of a tie, the floating-point number having unbounded exponent range and a $p$-bit significand with the least-significant bit equal to 0 is used).

`inc_flag` is set to 1 if the magnitude of the value returned is greater than $x$.
`xx_flag` is set to 1 if the value returned is not equal to $x$.

**bfp_ROUND_TRUNC(p, x)**

$x$ is a binary floating-point value that is represented in the binary floating-point working format and has unbounded exponent range and significand precision. $x$ must be rounded as presented, without prenormalization.

$p$ is an integer value specifying the precision (i.e., number of bits) the significand is rounded to.

Return the largest floating-point number having unbounded exponent range and a significand with a width of $p$ bits that is lesser or equal in value to $x$ if $x>0$, or the smallest floating-point number having unbounded exponent range but double-precision significand precision that is greater or equal in value to $x$ if $x<0$.

`inc_flag` is set to 1 if the magnitude of the value returned is greater than $x$.
`xx_flag` is set to 1 if the value returned is not equal to $x$. 
**bfp_SQUARE_ROOT(x)**

x is a binary floating-point value that is represented in the binary floating-point working format and has unbounded exponent range and significand precision.

If x is an SNaN, vxsnan_flag is set to 1.
Otherwise, if x is negative and non-zero, vxsqrt_flag is set to 1.

If x is a QNaN, return x.
Otherwise, if x is an SNaN, return x represented as a QNaN.
Otherwise, if x is -Zero, return -Zero.
Otherwise, if x is negative, return the standard QNaN.
Otherwise, return the normalized square root of x, represented in the binary floating-point working format, having unbounded range and precision.

**bfp16_CONVERT_FROM_BFP(x)**

x is a floating-point value represented in the binary floating-point working format.

If x.class.QNaN=1, do the following.
  Bit 0 of result is set to the value of x.sign.
  Bits 1:5 of result are set to the value 0b11111.
  Bits 6:15 of result are set to the value of bits 1:10 of x.significand.

Otherwise, if x.class.Infinity=1, do the following.
  Bit 0 of result is set to the value of x.sign.
  Bits 1:5 of result are set to the value 0b11111.
  Bits 6:15 of result are set to 0.

Otherwise, if x.class.Zero=1, do the following.
  Bit 0 of result is set to the value of x.sign.
  Bits 1:15 of result are set to 0.

Otherwise, if x.exponent is less than -14 and UE=0, do the following.
  Bit 0 of result is set to the value of x.sign.
  sh_cnt is set to the difference, -14 - x.exponent.
  Bits 1:5 of result are set to 0b00000.
  Bits 6:15 of result are set to bits 1:10 of x.significand shifted right by sh_cnt bits.

Otherwise, if x.exponent is less than -14 and UE=1, result is undefined.
Otherwise, if x.exponent is greater than 15 and OE=1, result is undefined.

Otherwise, do the following.
  Bit 0 of result is set to the value of x.sign.
  Bits 1:5 of result are set to the sum, x.exponent + 15.
  Bits 6:15 of result are set to bits 1:10 of x.significand.

Return result.

**bfp32_ABSOLUTE(x)**

x is a floating-point value represented in single-precision format.

Return x with its sign set to 0.

**bfp32_CONVERT_FROM_BFP(x)**

x is a floating-point value represented in the binary floating-point working format.

If x.class.QNaN=1, do the following.
  Bit 0 of result is set to the value of x.sign.
  Bits 1:8 of result are set to the value 0b1111_1111.
  Bits 9:31 of result are set to the value of bits 1:23 of x.significand.
Otherwise, if $x.class.Infinity=1$, do the following.
- Bit 0 of $\text{result}$ is set to the value of $x.sign$.
- Bits 1:9 of $\text{result}$ are set to the value $0b1111_1111$.
- Bits 9:31 of $\text{result}$ are set to 0.

Otherwise, if $x.class.Zero=1$, do the following.
- Bit 0 of $\text{result}$ is set to the value of $x.sign$.
- Bits 1:31 of $\text{result}$ are set to 0.

Otherwise, if $x.exponent$ is less than $-126$ and $UE=0$, do the following.
- Bit 0 of $\text{result}$ is set to the value of $x.sign$.
- $\text{sh_cnt}$ is set to the difference, $-126 - x.exponent$.
- Bits 1:8 of $\text{result}$ are set to $0b0000_0000$.
- Bits 9:31 of $\text{result}$ are set to bits 1:23 of $x.significand$ shifted right by $\text{sh_cnt}$ bits.

Otherwise, if $x.exponent$ is less than $-126$ and $UE=1$, $\text{result}$ is undefined.

Otherwise, if $x.exponent$ is greater than $127$ and $OE=1$, $\text{result}$ is undefined.

Otherwise, do the following.
- Bit 0 of $\text{result}$ is set to the value of $x.sign$.
- Bits 1:8 of $\text{result}$ are set to the sum, $x.exponent + 127$.
- Bits 9:31 of $\text{result}$ are set to bits 1:23 of $x.significand$.

Return $\text{result}$.

### bfp32\_CONVERT\_FROM\_BFP64$(x)$

$x$ is a single-precision floating-point value in double-precision format.

Returns the value $x$ in single-precision format. $x$ must be representable in single-precision, or else $\text{result}$ returned is undefined. $x$ may require denormalization. No rounding is performed. If $x$ is a SNaN, it is converted to a single-precision SNaN having the same payload as $x$.

$\text{sign} \leftarrow x.\text{bit}[0]$
$\text{exp} \leftarrow x.\text{bit}[1:11] - 1023$
$\text{frac} \leftarrow x.\text{bit}[12:63]$

    return(result)
end

bfp32_MAXIMUM(x, y)
x is a binary floating-point value that is represented in single-precision format.
y is a binary floating-point value that is represented in single-precision format.

If x or y is an SNaN, vxsnan_flag is set to 1.
If x is a QNaN and y is not a NaN, return y.
Otherwise, if x is a QNaN, return x.
Otherwise, if x is an SNaN, return x represented as a QNaN.
Otherwise, if y is a QNaN, return x.
Otherwise, if y is an SNaN, return y represented as a QNaN.
Otherwise, return the greater of x and y, where +0 is considered greater than -0.

bfp32_MINIMUM(x, y)
x is a binary floating-point value that is represented in single-precision format.
y is a binary floating-point value that is represented in single-precision format.

If x or y is an SNaN, vxsnan_flag is set to 1.
If x is a QNaN and y is not a NaN, return y.
Otherwise, if x is a QNaN, return x.
Otherwise, if x is an SNaN, return x represented as a QNaN.
Otherwise, if y is a QNaN, return x.
Otherwise, if y is an SNaN, return y represented as a QNaN.
Otherwise, return the lesser of x and y, where -0 is considered less than +0.

bfp32_NEGATE(x)
x is a floating-point value represented in single-precision format.

Return x with its sign complemented.

bfp32_NEGATIVE_ABSOLUTE(x)
x is a floating-point value represented in single-precision format.

Return x with its sign set to 1.

bfp64_ABSOLUTE(x)
x is a floating-point value represented in double-precision format.

Return x with its sign set to 0.

bfp64_CONVERT_FROM_BFP(x)
x is a floating-point value represented in the binary floating-point working format.

If x.class.QNaN=1, do the following.
    Bit 0 of result is set to the value of x.sign.
    Bits 1:11 of result are set to the value 0b111_1111_1111.
    Bits 12:63 of result are set to the value of bits 1:52 of x.significand.
Otherwise, if \(x.\text{class}.\text{Infinity}=1\), do the following.

- Bit 0 of result is set to the value of \(x.\text{sign}\).
- Bits 1:11 of result are set to the value \(0\text{b}11_111_1111\).
- Bits 12:63 of result are set to 0.

Otherwise, if \(x.\text{class}.\text{Zero}=1\), do the following.

- Bit 0 of result is set to the value of \(x.\text{sign}\).
- Bits 1:63 of result are set to 0.

Otherwise, if \(x.\text{exponent}\) is less than \(-1022\) and \(UE=0\), do the following.

- Bit 0 of result is set to the value of \(x.\text{sign}\).
- \(sh\_cnt\) is set to the difference, \(-1022 - x.\text{exponent}\).
- Bits 1:11 of result are set to \(0\text{b}000\_0000\_0000\).
- Bits 12:63 of result are set to bits 1:52 of \(x.\text{significand}\) shifted right by \(sh\_cnt\) bits.

Otherwise, if \(x.\text{exponent}\) is less than \(-1022\) and \(UE=1\), result is undefined.

Otherwise, if \(x.\text{exponent}\) is greater than \(1023\) and \(OE=1\), result is undefined.

Otherwise, do the following.

- Bit 0 of result is set to the value of \(x.\text{sign}\).
- Bits 1:11 of result are set to the sum, \(x.\text{exponent} + 1023\).
- Bits 12:63 of result are set to bits 1:52 of \(x.\text{significand}\).

Return result.

\[ \textbf{bf64\_NEGATE}(x) \]

\( x \) is a floating-point value represented in double-precision format.

Return \( x \) with its sign complemented.

\[ \textbf{bf64\_NEGATIVE\_ABSOLUTE}(x) \]

\( x \) is a floating-point value represented in double-precision format.

Return \( x \) with its sign set to 1.

\[ \textbf{bf64\_MAXIMUM}(x, y) \]

\( x \) is a binary floating-point value that is represented in double-precision format.
\( y \) is a binary floating-point value that is represented in double-precision format.

If \( x \) or \( y \) is an \( SNaN \), \( vx\_snan\_flag \) is set to 1.

If \( x \) is a \( QNaN \) and \( y \) is not a \( NaN \), return \( y \).
Otherwise, if \( x \) is a \( QNaN \), return \( x \).
Otherwise, if \( x \) is an \( SNaN \), return \( x \) represented as a \( QNaN \).
Otherwise, if \( y \) is a \( QNaN \), return \( x \).
Otherwise, if \( y \) is an \( SNaN \), return \( y \) represented as a \( QNaN \).
Otherwise, return the greater of \( x \) and \( y \), where \(+0\) is considered greater than \(-0\).

\[ \textbf{bf64\_MAXIMUM\_TYPE\_C}(x, y) \]

\( x \) is a binary floating-point value that is represented in double-precision format.
\( y \) is a binary floating-point value that is represented in double-precision format.

If \( x \) or \( y \) is an \( SNaN \), \( vx\_snan\_flag \) is set to 1.

If \( x \) or \( y \) is a \( NaN \), return \( y \).
Otherwise, if \( x \) is greater than \( y \), return \( x \).
Otherwise, return \( y \).
`bfp64_MAXIMUM_TYPE_J(x, y)`
- $x$ is a binary floating-point value that is represented in double-precision format.
- $y$ is a binary floating-point value that is represented in double-precision format.

If $x$ or $y$ is an SNaN, $vxsnan\_flag$ is set to 1.

If $x$ is a NaN, return $x$.
Otherwise, if $y$ is a NaN, return $y$.
Otherwise, if both $x$ and $y$ are Zero and either $x$ or $y$ is a +Zero, return +Zero.
Otherwise, if both $x$ and $y$ are Zero and both $x$ and $y$ are -Zero, return -Zero.
Otherwise, if $x$ is greater than $y$, return $x$.
Otherwise, return $y$.

`bfp64_MINIMUM(x, y)`
- $x$ is a binary floating-point value that is represented in double-precision format.
- $y$ is a binary floating-point value that is represented in double-precision format.

If $x$ or $y$ is an SNaN, $vxsnan\_flag$ is set to 1.

If $x$ is a QNaN and $y$ is not a NaN, return $y$.
Otherwise, if $x$ is a QNaN, return $x$.
Otherwise, if $x$ is an SNaN, return $x$ represented as a QNaN.
Otherwise, if $y$ is a QNaN, return $x$.
Otherwise, if $y$ is an SNaN, return $y$ represented as a QNaN.
Otherwise, return the lesser of $x$ and $y$, where -0 is considered less than +0.

`bfp64_MINIMUM_TYPE_C(x, y)`
- $x$ is a binary floating-point value that is represented in double-precision format.
- $y$ is a binary floating-point value that is represented in double-precision format.

If $x$ or $y$ is an SNaN, $vxsnan\_flag$ is set to 1.

If $x$ or $y$ is a NaN, return $y$.
Otherwise, if $x$ is less than $y$, return $x$.
Otherwise, return $y$.

`bfp64_MINIMUM_TYPE_J(x, y)`
- $x$ is a binary floating-point value that is represented in double-precision format.
- $y$ is a binary floating-point value that is represented in double-precision format.

If $x$ or $y$ is an SNaN, $vxsnan\_flag$ is set to 1.

If $x$ is a NaN, return $x$.
Otherwise, if $y$ is a NaN, return $y$.
Otherwise, if both $x$ and $y$ are Zero and either $x$ or $y$ is a -Zero, return -Zero.
Otherwise, if both $x$ and $y$ are Zero and both $x$ and $y$ are +Zero, return +Zero.
Otherwise, if $x$ is less than $y$, return $x$.
Otherwise, return $y$.

`bfp128_ABSOLUTE(x)`
- $x$ is a floating-point value represented in quad-precision format.

Return $x$ with its sign set to 0.
Chapter 7. Vector-Scalar Extension Facility

bfp128_CONVERT_FROM_BFP(x)

x is a quad-precision floating-point value that is represented in the binary floating-point working format.

If x is a QNaN,
   the contents of bit 0 of result are set to the value of x.sign,
   the contents of bits 1:15 of result are set to the value 0b111_1111_1111_1111, and
   the contents of bits 16:127 of result are set to the value of bits 1:112 of x.significand.

Otherwise, if x is a Zero,
   the contents of bit 0 of result are set to the value of x.sign, and
   the contents of bits 1:15 of result are set to the value 0b000_0000_0000_0000, and
   the contents of bits 16:127 of result are set to the value 0x0000_0000_0000_0000_0000_0000_0000.

Otherwise, if x is an Infinity,
   the contents of bit 0 of result are set to the value of x.sign, and
   the contents of bits 1:15 of result are set to the value 0b111_1111_1111_1111, and
   the contents of bits 16:127 of result are set to the value 0x0000_0000_0000_0000_0000_0000_0000.

Otherwise, do the following.
   If the exponent of x is less than -16382,
      the contents of bit 0 of result are set to the value of x.sign,
      the contents of bits 1:15 of result are set to the value 0b000_0000_0000_0000, and
      the contents of bits 16:127 of result are set to the value of bits 1:112 of the significand of x shifted right by N bits, where N is the value -16382 subtracted by the value of the exponent of x.
   Otherwise,
      the contents of bit 0 of result are set to the value of x.sign,
      the contents of bits 1:15 of result are set to the sum of the exponent of x and 16383, and
      the contents of bits 16:127 of result are set to the value of bits 1:112 of the significand of x.

Return result (i.e., x in quad-precision format).

bfp128_NEGATE(x)

x is a floating-point value represented in quad-precision format.

Return x with its sign complemented.

bfp128_NEGATIVE_ABSOLUTE(x)

x is a floating-point value represented in quad-precision format.

Return x with its sign set to 1.

si64_CONVERT_FROM_BFP(x)

x is an integer value represented in the binary floating-point working format.

Return the value x in signed doubleword integer format.

ui64_CONVERT_FROM_BFP(x)

x is an integer value represented in the binary floating-point working format.

Return the value x in 64-bit unsigned integer format.

bfp128_MAXIMUM_TYPE_C(x,y)

x is a binary floating-point value that is represented in quad-precision format.

y is a binary floating-point value that is represented in quad-precision format.

If x or y is an SNaN, vxsnan_flag is set to 1.

If x or y is a NaN, return y.

Otherwise, if x is greater than y, return x.

Otherwise, return y.
\textbf{bfp128\_MAXI\_NUM\_TYPE\_J}(x, y)

\textit{x} is a binary floating-point value that is represented in quad-precision format.
\textit{y} is a binary floating-point value that is represented in quad-precision format.

If \textit{x} or \textit{y} is an SNaN, \texttt{vxsnan\_flag} is set to 1.

If \textit{x} is a NaN, return \textit{x}.
Otherwise, if \textit{y} is a NaN, return \textit{y}.
Otherwise, if both \textit{x} and \textit{y} are Zero and either \textit{x} or \textit{y} is a +Zero, return +Zero.
Otherwise, if both \textit{x} and \textit{y} are Zero and both \textit{x} and \textit{y} are -Zero, return -Zero.
Otherwise, if \textit{x} is greater than \textit{y}, return \textit{x}.
Otherwise, return \textit{y}.

\textbf{bfp128\_MINI\_NUM\_TYPE\_C}(x, y)

\textit{x} is a binary floating-point value that is represented in quad-precision format.
\textit{y} is a binary floating-point value that is represented in quad-precision format.

If \textit{x} or \textit{y} is an SNaN, \texttt{vxsnan\_flag} is set to 1.

If \textit{x} or \textit{y} is a NaN, return \textit{y}.
Otherwise, if \textit{x} is less than \textit{y}, return \textit{x}.
Otherwise, return \textit{y}.

\textbf{bfp128\_MINI\_NUM\_TYPE\_J}(x, y)

\textit{x} is a binary floating-point value that is represented in quad-precision format.
\textit{y} is a binary floating-point value that is represented in quad-precision format.

If \textit{x} or \textit{y} is an SNaN, \texttt{vxsnan\_flag} is set to 1.

If \textit{x} is a NaN, return \textit{x}.
Otherwise, if \textit{y} is a NaN, return \textit{y}.
Otherwise, if both \textit{x} and \textit{y} are Zero and either \textit{x} or \textit{y} is a -Zero, return -Zero.
Otherwise, if both \textit{x} and \textit{y} are Zero and both \textit{x} and \textit{y} are +Zero, return +Zero.
Otherwise, if \textit{x} is less than \textit{y}, return \textit{x}.
Otherwise, return \textit{y}.

\textbf{EXTZ32}(x)

Result of extending the \textit{b}-bit value \textit{x} on the left with 32-\textit{b} zeros, forming a 32-bit value.

\begin{verbatim}
b ← LENGTH(x)
result.bit[0:31-b] ← 0
result.bit[32-b:31] ← x
\end{verbatim}

\textbf{EXTZ64}(x)

Result of extending the \textit{b}-bit value \textit{x} on the left with 64-\textit{b} zeros, forming a 64-bit value.

\begin{verbatim}
b ← LENGTH(x)
result.bit[0:63-b] ← 0
result.bit[64-b:63] ← x
\end{verbatim}

\textbf{EXTZ128}(x)

Result of extending the \textit{b}-bit value \textit{x} on the left with 128-\textit{b} zeros, forming a 128-bit value.

\begin{verbatim}
b ← LENGTH(x)
result.bit[0:127-b] ← 0
result.bit[128-b:127] ← x
\end{verbatim}
fprf_CLASS_BFP16(x)

\( x \) is a floating-point value represented in half-precision format.

Return the 5-bit code that specifies the sign and class of \( x \).

Return \(0b10001\) if \( x \) is a Quiet NaN.
Return \(0b01001\) if \( x \) is a negative infinity.
Return \(0b00101\) if \( x \) is a positive infinity.
Return \(0b01010\) if \( x \) is a negative zero.
Return \(0b00010\) if \( x \) is a positive zero.
Return \(0b11100\) if \( x \) is a negative denormal value as represented in half-precision format.
Return \(0b10100\) if \( x \) is a positive denormal value as represented in half-precision format.
Return \(0b01100\) if \( x \) is a negative normal value as represented in half-precision format.
Return \(0b00100\) if \( x \) is a positive normal value as represented in half-precision format.

fprf_CLASS_BFP32(x)

\( x \) is a floating-point value represented in single-precision format.

Return the 5-bit code that specifies the sign and class of \( x \).

Return \(0b10001\) if \( x \) is a Quiet NaN.
Return \(0b01001\) if \( x \) is a negative infinity.
Return \(0b00101\) if \( x \) is a positive infinity.
Return \(0b01010\) if \( x \) is a negative zero.
Return \(0b00010\) if \( x \) is a positive zero.
Return \(0b11100\) if \( x \) is a negative denormal value as represented in single-precision format.
Return \(0b10100\) if \( x \) is a positive denormal value as represented in single-precision format.
Return \(0b01100\) if \( x \) is a negative normal value as represented in single-precision format.
Return \(0b00100\) if \( x \) is a positive normal value as represented in single-precision format.

fprf_CLASS_BFP64(x)

\( x \) is a floating-point value represented in double-precision format.

Return the 5-bit code that specifies the sign and class of \( x \).

Return \(0b10001\) if \( x \) is a Quiet NaN.
Return \(0b01001\) if \( x \) is a negative infinity.
Return \(0b00101\) if \( x \) is a positive infinity.
Return \(0b01010\) if \( x \) is a negative zero.
Return \(0b00010\) if \( x \) is a positive zero.
Return \(0b11100\) if \( x \) is a negative denormal value as represented in double-precision format.
Return \(0b10100\) if \( x \) is a positive denormal value as represented in double-precision format.
Return \(0b01100\) if \( x \) is a negative normal value as represented in double-precision format.
Return \(0b00100\) if \( x \) is a positive normal value as represented in double-precision format.

fprf_CLASS_BFP128(x)

\( x \) is binary floating-point value that is represented in quad-precision format.

Return the 5-bit characterization of the sign and class of \( x \).

Return \(0b10001\) if \( x \) is a Quiet NaN.
Return \(0b01001\) if \( x \) is negative and an infinity.
Return \(0b00100\) if \( x \) is negative and a normal number.
Return \(0b11100\) if \( x \) is negative and a denormal number.
Return \(0b00101\) if \( x \) is negative and a zero.
Return \(0b00010\) if \( x \) is positive and a zero.
Return \(0b10100\) if \( x \) is positive and a denormal number.
Return \(0b00100\) if \( x \) is positive and a normal number.
IsInf(x)
Return 1 if x is an Infinity, otherwise return 0.

IsNaN(x)
Return 1 if x is either an SNaN or a QNaN, otherwise return 0.

IsNeg(x)
Return 1 if x is a negative, nonzero value, otherwise return 0.

IsSNaN(x)
Return 1 if x is an SNaN, otherwise return 0.

IsZero(x)
Return 1 if x is a Zero, otherwise return 0.

reset_xflags()
vxsnan_flag is set to 0.
vxiem_flag is set to 0.
vxiv_flag is set to 0.
vxisi_flag is set to 0.
vxzdz_flag is set to 0.
vxsqrt_flag is set to 0.
vxcvi_flag is set to 0.
xx_flag is set to 0.
ux_flag is set to 0.
xx_flag is set to 0.
ux_flag is set to 0.

SetFX(x)
x is one of the exception flags in the FPSCR.
If the contents of x is 0, FX and x are set to 1.

si128_CONVERT_FROM_BFP(x)
x is an integer value represented in the binary floating-point working format.
If x is a NaN,
vxcvi_flag is set to 1,
vxsnan_flag is set to 1 if x is an SNaN, and
return 0x8000_0000_0000_0000_0000_0000_0000_0000,
Otherwise, do the following.
Let rnd be the value x truncated to an integral value.
Let exponent be the unbiased exponent of rnd.
Let significand be the significand of rnd.
If rnd is greater than 2^{127}-1,
vxcvi_flag is set to 1, and
return 0x7FFF_FFFF_FFFF_FFFF_FFFF_FFFF_FFFF_FFFF.
Otherwise, if rnd is less than -2^{127},
vxcvi_flag is set to 1, and
return 0x8000_0000_0000_0000_0000_0000_0000_0000.
Otherwise,
xx_flag is set to 1 if rnd is inexact,
inc_flag is set to 0,
\textit{significand} is shifted right by the difference 127-\textit{exponent} with 0s shifted in, if \textit{rnd} is negative, \textit{significand} is negated, and return bits 0:127 of \textit{significand}.

\texttt{si32\_CHOP(x)}
\hspace{1em} \textit{x} is a signed integer value.

Return the rightmost 32 bits of \textit{x} in 32-bit signed integer format.

\texttt{si32\_CLAMP(x)}
\hspace{1em} \textit{x} is a signed integer value.

If \textit{x} is greater than \texttt{2^{31}-1}, \textit{result} is the value \texttt{2^{31}-1}, and \textit{SAT} is set to 1.

Otherwise, if \textit{x} is less than \texttt{-2^{31}}, \textit{result} is the value \texttt{-2^{31}}, and \textit{SAT} is set to 1.

Otherwise, \textit{result} is \textit{x}.

Return \textit{x} in 32-bit signed integer format.

\texttt{ui128\_CONVERT\_FROM\_BFP(x)}
\hspace{1em} \textit{x} is an integer value represented in the binary floating-point working format.

If \textit{x} is a NaN,
\hspace{2em} \texttt{vxcvi\_flag} is set to 1,
\hspace{2em} \texttt{vxsnan\_flag} is set to 1 if \textit{x} is an SNaN, and
\hspace{2em} return \texttt{0x0000_0000_0000_0000_0000_0000_0000_0000}.

Otherwise, do the following.
\hspace{2em} Let \texttt{rnd} be the value \textit{x} truncated to an integral value.
\hspace{2em} Let \texttt{exponent} be the unbiased exponent of \texttt{rnd}.
\hspace{2em} Let \textit{significand} be the significand of \texttt{rnd}.

If \texttt{rnd} is greater than \texttt{2^{128}-1},
\hspace{2em} \texttt{vxcvi\_flag} is set to 1, and
\hspace{2em} return \texttt{0xFFFF_FFFF_FFFF_FFFF_FFFF_FFFF_FFFF_FFFF}.

Otherwise, if \texttt{rnd} is less than 0,
\hspace{2em} \texttt{vxcvi\_flag} is set to 1, and
\hspace{2em} return \texttt{0x0000_0000_0000_0000_0000_0000_0000_0000}.

Otherwise,
\hspace{2em} \texttt{xx\_flag} is set to 1 if \texttt{rnd} is inexact,
\hspace{2em} \texttt{inc\_flag} is set to 0,
\hspace{2em} \textit{significand} is shifted right by the difference 127-\textit{exponent} with 0s shifted in, and
\hspace{2em} return bits 0:127 of \textit{significand}.

</table>

If MSR.VSX=0 then VSX_Unavailable();

If "lxsd" then

\( EA \leftarrow (RA|0) + \text{EXT64}(\text{DS}||0b00) \)

If "plxsd" & R=0 then

\( EA \leftarrow (RA|0) + \text{EXT64}(d0||d1) \)

If "plxsd" & R=1 then

\( EA \leftarrow \text{CIA} + \text{EXT64}(d0||d1) \)

\( \text{VSR}[\text{VRT}+32].\text{dword}[0] \leftarrow \text{MEN}(EA,8) \)

\( \text{VSR}[\text{VRT}+32].\text{dword}[1] \leftarrow 0x0000_0000_0000_0000 \)

Let \( XT \) be the value \( \text{VRT} + 32 \).

For \( \text{lxsd} \), let the effective address \( (EA) \) be the sum of the contents of register \( RA \), or the value 0 if \( RA=0 \), and the value \( DS||0b00 \), sign-extended to 64 bits.

For \( \text{plxsd} \) with \( R=0 \), let the effective address \( (EA) \) be the sum of the contents of register \( RA \), or the value 0 if \( RA=0 \), and the value \( d0||d1 \), sign-extended to 64 bits.

For \( \text{plxsd} \) with \( R=1 \), let the effective address \( (EA) \) be the sum of the address of the instruction and the value \( d0||d1 \), sign-extended to 64 bits.

When Big-Endian byte ordering is employed, the contents of the doubleword in storage at address \( EA \) are placed into \( \text{load_data} \) in such an order that;

– the contents of the byte in storage at address \( EA \) are placed into byte 0 of \( \text{load_data} \),

– the contents of the byte in storage at address \( EA+1 \) are placed into byte 1 of \( \text{load_data} \), and so forth until

– the contents of the byte in storage at address \( EA+7 \) are placed into byte 7 of \( \text{load_data} \).

When Little-Endian byte ordering is employed, let \( \text{load_data} \) be the contents of the doubleword in storage at address \( EA \) such that;

– the contents of the byte in storage at address \( EA \) are placed into byte 7 of \( \text{load_data} \),

– the contents of the byte in storage at address \( EA+1 \) are placed into byte 6 of \( \text{load_data} \), and so forth until

– the contents of the byte in storage at address \( EA+7 \) are placed into byte 0 of \( \text{load_data} \).

\( \text{load_data} \) is placed into doubleword element 0 of \( \text{VSR}[\text{VRT}+32] \).

The contents of doubleword element 1 of \( \text{VSR}[\text{VRT}+32] \) are set to 0.

For \( \text{plxsd} \), if \( R \) is equal to 1 and \( RA \) is not equal to 0, the instruction form is invalid.

if MSR.VSX=0 then VSX_Unavailable()

EA ← ((RA=0) ? 0 : GPR[RA]) + GPR[RB]

VSR[32×TX+T].dword[0] ← MEM(EA, 8)
VSR[32×TX+T].dword[1] ← MEM(EA+8, 8)

Let XT be the value 32×TX + T.

Let EA be the sum of the contents of GPR[RA], or 0 if RA is equal to 0, and the contents of GPR[RB].

For each integer value i from 0 to 1, do the following.

When Big-Endian byte ordering is employed, the contents of the doubleword in storage at address EA+8×i are placed into `load_data` in such an order that;

- the contents of the byte in storage at address EA+8×i are placed into byte element 0 of `load_data`,
- the contents of the byte in storage at address EA+8×i+1 are placed into byte element 1 of `load_data`, and so forth until
- the contents of the byte in storage at address EA+8×i+7 are placed into byte element 7 of `load_data`.

`load_data` is placed into doubleword element i of VSR[XT].

Special Registers Altered

None

Programming Note

`lxvd2x, lxvv4x, lxvh8x, lxvb16x`, and `lxvx` exhibit identical behavior in Big-Endian mode.

if “plxvp” & R=0 then EA ← EAbase + EAdisp
if “plxvp” & R=1 then EA ← CIA + EAdisp

load_data ← MEM(EA, 32)

VSR[32×TX+2×Tp] ← load_data.bit[0:127]
VSR[32×TX+2×Tp+1] ← load_data.bit[128:255]

Let XTp be the value 32×TX + 2×Tp (i.e., only even values of XTp can be encoded in the instruction).

Let EAbase be the contents of GPR[RA], or 0 if RA=0.

For **lxvp**, let the effective address (EA) be the sum of the integer value in GPR[RA], or 0 if RA=0, and the value DQ||0b0000, sign-extended to 64 bits.

For **plxvp**, if R=0, let the effective address (EA) be the sum of the integer value in GPR[RA], or 0 if RA=0, and the value d0||d1, sign-extended to 64 bits.

For **plxvp**, if R=1, let the effective address (EA) be the sum of the address of the instruction and the value d0||d1, sign-extended to 64 bits.

When Big-Endian byte ordering is employed, the contents of the octword in storage at address EA are placed into load_data in such an order that:

- the contents of the byte in storage at address EA are placed into byte 0 of load_data,
- the contents of the byte in storage at address EA+1 are placed into byte 1 of load_data, and so forth until
- the contents of the byte in storage at address EA+31 are placed into byte 31 of load_data.

When Little-Endian byte ordering is employed, the contents of the octword in storage at address EA are placed into load_data in such an order that:

- the contents of the byte in storage at address EA are placed into byte 31 of load_data,
- the contents of the byte in storage at address EA+1 are placed into byte 30 of load_data, and so forth until
- the contents of the byte in storage at address EA+31 are placed into byte 0 of load_data.

Bits 0-127 of load_data are placed into VSR[XTp].

Bits 128-255 of load_data is placed into VSR[XTp+1].

For **plxvp**, if R is equal to 1 and RA is not equal to 0, the instruction form is invalid.

EA ← ((RA=0) ? 0 : GPR[RA]) + GPR[RB]

load_data ← MEM(EA,32)

VSR[32×TX+2×Tp] ← load_data.bit[0:127]

VSR[32×TX+2×Tp+1] ← load_data.bit[128:255]

Let XTp be the value $32 \times TX + 2 \times Tp$ (i.e., only even values of $XTp$ can be encoded in the instruction).

Let the effective address (EA) be the sum of the integer value in GPR[RA], or 0 if RA=0, and the integer value in GPR[RB].

When Big-Endian byte ordering is employed, the contents of the octword in storage at address EA are placed into load_data in such an order that;

- the contents of the byte in storage at address EA are placed into byte 0 of load_data,
- the contents of the byte in storage at address EA+1 are placed into byte 1 of load_data, and so forth until
- the contents of the byte in storage at address EA+31 are placed into byte 31 of load_data.

When Little-Endiа byte ordering is employed, the contents of the octword in storage at address EA are placed into load_data in such an order that;

- the contents of the byte in storage at address EA are placed into byte 31 of load_data,
- the contents of the byte in storage at address EA+1 are placed into byte 30 of load_data, and so forth until
- the contents of the byte in storage at address EA+31 are placed into byte 0 of load_data.

Bits 0-127 of load_data are placed into VSR[XTp].

Bits 128-255 of load_data is placed into VSR[XTp+1].

**Special Registers Altered:**

None

**Programming Note**

For best performance, EA should be word-aligned.

if MSR.VSX=0 then VSX_Unavailable()

EA ← ((RA=0) ? 0 : GPR[RA]) + GPR[RB]

VSR[32×TX+T].word[0] ← MEM(EA, 4)
VSR[32×TX+T].word[1] ← MEM(EA+4, 4)
VSR[32×TX+T].word[2] ← MEM(EA+8, 4)
VSR[32×TX+T].word[3] ← MEM(EA+12, 4)

Let XT be the value 32×TX + T.

Let EA be the sum of the contents of GPR[RA], or 0 if RA is equal to 0, and the contents of GPR[RB].

For each integer value i from 0 to 3, do the following.

When Big-Endian byte ordering is employed, the contents of the word in storage at address EA+4×i are placed into load_data in such an order that;

- the contents of the byte in storage at address EA+4×i are placed into load_data, and
- the contents of the byte in storage at address EA+4×i+1 are placed into byte element 1 of load_data,
- the contents of the byte in storage at address EA+4×i+2 are placed into byte element 2 of load_data, and
- the contents of the byte in storage at address EA+4×i+3 are placed into byte element 3 of load_data.

When Little-Endian byte ordering is employed, the contents of the word in storage at address EA+4×i are placed into word element i of VSR[XT] in such an order that;

- the contents of the byte in storage at address EA+4×i are placed into byte element 3 of load_data, and
- the contents of the byte in storage at address EA+4×i+1 are placed into byte element 2 of load_data,
- the contents of the byte in storage at address EA+4×i+2 are placed into byte element 1 of load_data, and
- the contents of the byte in storage at address EA+4×i+3 are placed into byte element 0 of load_data.

load_data is placed into word element i of VSR[XT].

Special Registers Altered
None

**Programming Note**

lxwd2x, lxvw4x, lxvh8x, lxvb16x, and lxvx exhibit identical behavior in Big-Endian mode.
Load VSX Vector Word & Splat Indexed X-form

```plaintext
if MSR.VSX=0 then VSX_Unavailable();

EAbase ← (RA=0) ? 0 : GPR[RA]
if "stxvp" then
    EAdisp ← EXT64(DQ || 0b0000)
if "pstxvp" then
    EAdisp ← EXT64(d0 || d1)

if "stxvp" then EA ← EAbase + EAdisp
if "pstxvp" & R=0 then EA ← EAbase + EAdisp
if "pstxvp" & R=1 then EA ← CIA + EAdisp

store_data.bit[0:127] ← VSR[32×SX+2×Sp]
store_data.bit[128:255] ← VSR[32×SX+2×Sp+1]
MEM(EA,32) ← store_data
```

Let **XSp** be the value 32×SX + 2×Sp (i.e., only even values of XSp can be encoded in the instruction).

For **stxvp**, let the effective address (EA) be the sum of the integer value in GPR[RA], or 0 if RA=0 and the value DQ || 0b0000.

For **pstxvp**, if R=0, let the effective address (EA) be the sum of the integer value in GPR[RA], or 0 if RA=0, and the value d0 || d1, sign-extended to 64 bits.

For **pstxvp**, if R=1, let the effective address (EA) be the sum of the address of the instruction and the value d0 || d1, sign-extended to 64 bits.

Let **store_data** be the contents of VSR[XSp] concatenated with VSR[XSp+1].

When Big-Endian byte ordering is employed, **store_data** is placed into the octword in storage at address EA in such an order that;

- byte 0 of **store_data** is placed into the byte in storage at address EA,
- byte 1 of **store_data** is placed into the byte in storage at address EA+1, and so forth until
- byte 31 of **store_data** is placed into the byte in storage at address EA+31.

When Little-Endian byte ordering is employed, **store_data** is placed into the octword in storage at address EA in such an order that;

- byte 0 of **store_data** is placed into the byte in storage at address EA+31,
- byte 1 of **store_data** is placed into the byte in storage at address EA+30, and so forth until
- byte 31 of **store_data** is placed into the byte in storage at address EA.

For **pstxvp**, if R is equal to 1 and RA is not equal to 0, the instruction form is invalid.

### Notes

- **src2** is added\(^1\) to **src1**, producing a sum having unbounded range and precision.
- The sum is normalized\(^2\).

### Actions

- See Table 61, “Actions for xsadddp,” on page 660.

### Intermediate Result

- The intermediate result is rounded to double-precision using the rounding mode specified by RN.

### Final Result

- The result is placed into doubleword element 0 of **VSR[XT]** in double-precision format.

### Contents

- The contents of doubleword element 1 of **VSR[XT]** are set to 0.

### Flags

- **FPRF** is set to the class and sign of the result. **FR** is set to indicate if the result was incremented when rounded. **FI** is set to indicate the result is inexact.

### Trap-Enabled

- If a trap-enabled invalid operation exception occurs, **VSR[XT]** and **FPRF** are not modified, and **FR** and **FI** are set to 0.

### Data Layout

- See Table 63, “VSX Scalar Floating-Point Final Result,” on page 662.

### Special Registers Altered

- **FPRF** FR FI FX UX XX VXSNAN VXISI

### Programming Note

- Previous versions of the architecture allowed the contents of doubeelement 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

---

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.

2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Explanation:

src1 The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2 The double-precision floating-point value in doubleword element 0 of VSR[XB].
dQNaN Default quiet NaN (0x7FF8_0000_0000_0000).
NZF Nonzero finite number.
Resz Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs).
A(x,y) Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.
Note: If x = -y, v is considered to be an exact-zero-difference result (Resz).
Q(x) Return a QNaN with the payload of x.
v The intermediate result having unbounded significand precision and unbounded exponent range.

</tr>
</tbody>
</table>

**Explanation:**

1. This situation cannot occur.
2. The precise intermediate result defined in the instruction having unbounded range and precision.
3. The significand of \( v \) is shifted right by the amount of the difference between the target rounding precision \( E_{\text{min}} \) and the unbiased exponent of \( v \). The unbiased exponent of the denormalized value is \( E_{\text{min}} \). The significand of the denormalized value has unbounded significant precision.

\[
E_{\text{min}} = \begin{cases} 
-16382 & \text{(quad-precision)} \\
-16382 & \text{(double-extended-precision)} \\
-1022 & \text{(double-precision)} \\
-1022 & \text{(single-precision)}
\end{cases}
\]

4. Operates only to add operations involving source operands having the same magnitude and different signs or subtract operations involving source operands having the same magnitude and same signs. Whether +Zero or -Zero is returned is determined by the setting of the rounding mode in \( \text{RN} \), even when the rounding mode is overidden to Round to Odd.

\[
\text{round}(x) = \begin{cases} 
+1 & \text{if } x \geq 0 \\
-1 & \text{if } x < 0
\end{cases}
\]

5. The significand of \( x \) is rounded to the target rounding precision according to the rounding mode specified in \( \text{FPSCR}. \text{RN} \). Exponent range of the rounded result is unbounded. See Section 7.3.2.6.

6. Largest (in magnitude) representable normalized number in the target rounding precision format.

\[
\text{N}_{\text{max}} = \begin{cases} 
2^{127} x 1.0000000000000000000000000000000 & \text{(quad-precision)} \\
2^{127} x 1.0000000000000000000000000000000 & \text{(double-extended-precision)} \\
2^{1023} x 1.0000000000000000000000000000000 & \text{(double-precision)} \\
2^{1023} x 1.0000000000000000000000000000000 & \text{(single-precision)}
\end{cases}
\]

7. Smallest (in magnitude) representable normalized number in the target rounding precision format.

\[
\text{N}_{\text{min}} = \begin{cases} 
2^{-127} x 1.0000000000000000000000000000000 & \text{(double-precision)} \\
2^{-127} x 1.0000000000000000000000000000000 & \text{(single-precision)}
\end{cases}
\]

8. Least significant bit in the target precision format’s significand (Unit in the Last Position).

---

### Explanation:

- The results do not depend on this condition.
- \( T(x) \) places the result into the target VSR.
  - For scalar single-precision and double-precision results
    \[ \text{VR}[\text{XT}] \text{.dword}[0] \leftarrow \text{bfpu64\_CONVERT\_FROM\_BFPU}(r) \]
    \[ \text{VR}[\text{XT}] \text{.dword}[1] \leftarrow 0x0000\_0000\_0000\_0000 \]
  - For scalar quad-precision results
    \[ \text{VR}[\text{VR}+32] \leftarrow \text{bfpu128\_CONVERT\_FROM\_BFPU}(r) \]
- \( \text{class\_bfpu}(x) \)
  - Sets \( \text{FPSCR.\_FRF} \) to the sign and class of \( x \).
  - \( \text{FPSCR.\_FRF} \leftarrow \text{fprf\_CLASS\_BFPU32}(x) \) (single-precision)
  - \( \text{FPSCR.\_FRF} \leftarrow \text{fprf\_CLASS\_BFPU64}(x) \) (double-precision)
  - \( \text{FPSCR.\_FRF} \leftarrow \text{fprf\_CLASS\_BFPU128}(x) \) (quad-precision)
- \( \text{fx}(x) \)
  - \( \text{FPSCR.\_FX} \) is set to 1 if \( \text{FPSCR.\_x}=0 \).
  - \( \text{FPSCR.\_x} \) is set to 1.
- \( \text{fi}(x) \)
  - \( \text{FPSCR.\_FR} \) is set to the value \( x \).
- \( \beta \)
  - Wrap adjust
    - \( \beta = 2\frac{1}{2} \) (single-precision)
    - \( \beta = 2\frac{3}{3} \) (double-precision)
    - \( \beta = 2\frac{4}{3} \) (quad-precision)
  - See Table 7.4.3.2, “Action for OE=1,” on page 542 for trap-enabled Overflow exceptions.
  - See Table 7.4.4.2, “Action for UE=1,” on page 548 for trap-enabled Underflow exceptions.
- \( q \)
  - The value defined in Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 661, significand rounded to the target rounding precision, unbounded exponent range.
- \( r \)
  - The value defined in Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 661, significand rounded to the target rounding precision, exponent bounded to the target rounding precision format exponent range.
- \( \text{error}() \)
  - The system error handler is invoked for the trap-enabled exception if \( \text{MSR.\_FE0} \) and \( \text{MSR.\_FE1} \) are set to any mode other than the ignore-exception mode.

FPSCR.FR ← xx_flag
end
else do
FPSCR.FR ← 0b0
FPSCR.FI ← 0b0
end

Let XT be the value 32×TX + T.
Let XA be the value 32×AX + A.
Let XB be the value 32×BX + B.

Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

</tr>
</tbody>
</table>

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.

2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

src1 is added[1] to src1, producing a sum having unbounded range and precision.

The sum is normalized[2].

See Table 64, “Actions for xsaddsp,” on page 665.

The intermediate result is rounded to single-precision using the rounding mode specified by RN.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result as represented in single-precision format. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 662.

Explanation:
- src1: The double-precision floating-point value in doubleword element 0 of VSR[XA].
- src2: The double-precision floating-point value in doubleword element 0 of VSR[XB].
- dQNaN: Default quiet NaN (0x7FF8_0000_0000_0000).
- NZF: Nonzero finite number.
- Rezd: Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs).
- A[x,y]: Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.
- Note: If x = -y, v is considered to be an exact-zero-difference result (Rezd).
- Q[x]: Return a QNaN with the payload of x.
- v: The intermediate result having unbounded significand precision and unbounded exponent range.

Let src1 be the floating-point value in VSR[VRA+32] represented in quad-precision format.

Let src2 be the floating-point value in VSR[VRB+32] represented in quad-precision format.

If either src1 or src2 is a Signalling NaN, an Invalid Operation exception occurs and VXSNAN is set to 1.

If src1 and src2 are Infinity values having opposite signs, an Invalid Operation exception occurs and VXISI is set to 1.

If src1 is a Signalling NaN, the result is the Quiet NaN corresponding to src1.

Otherwise, if src1 is a Quiet NaN, the result is src1.

Otherwise, if src2 is a Signalling NaN, the result is the Quiet NaN corresponding to src2.

Otherwise, if src2 is a Quiet NaN, the result is src2.

Otherwise, if src1 and src2 are Infinity values having opposite signs, the result is the default Quiet NaN\[1\].

Otherwise, do the following.

The normalized sum of src2 added to src1 is produced with unbounded significand precision and exponent range.

See Table 65, “Actions for xaddqpo[1],” on page 667.

If the intermediate result is Tiny (i.e., the unbiased exponent is less than -16382) and UE=0, the significand is shifted right N bits, where N is the difference between -16382 and the unbiased exponent of the intermediate result. The exponent of the intermediate result is set to the value -16382.

If RO=1, let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by RN. The intermediate result is rounded to quad-precision using the specified rounding mode.

The result is placed into VSR[VRT+32] in quad-precision format.

FPRF is set to the class and sign of the result. FR is set to indicate if the rounded result was incremented. FI is set to indicate the result is inexact.

If a trap-disabled Invalid Operation exception occurs, FR and FI are set to 0.

If a trap-enabled Invalid Operation exception occurs, VSR[VRT+32] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 662.

Special Registers Altered:

\[\text{FPRF FR FI VXSNAN VXISI OX UX XX}\]

1. The quad-precision default Quiet NaN is the value, 0x7FFF_8000_0000_0000_0000_0000_0000.

Explanation:

src1: The quad-precision floating-point value in VSR[VRB+32].
src2: The quad-precision floating-point value in VSR[VRB+32].
dQNaN: Default quiet NaN (0x7FFF_8000_0000_0000_0000_0000_0000_0000).
NZF: Nonzero finite number.
Rezd: Exact-zero-difference result (addition of two finite numbers having same magnitude and opposite signs).
add(x,y): The floating-point value y is added to the floating-point value x. Return the normalized sum, having unbounded significand precision and exponent range.
When x = -y, v is considered to be an exact-zero-difference result (Rezd).
quiet(x): Convert x to the corresponding Quiet NaN by setting the most significant fraction bit to 1.
v: The intermediate result having unbounded significand precision and unbounded exponent range.

Table 65. Actions for xsaddqp[o]

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate difference.

2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Explanation:

- src1: The double-precision floating-point value in doubleword element 0 of VSR[XX].
- src2: The double-precision floating-point value in doubleword element 0 of VSR[XB].
- NZF: Nonzero finite number.
- C(x,y): The floating-point value x is compared to the floating-point value y, returning one of three 4-bit results.
  - 0b0100 when x is greater than y
  - 0b0100 when x is equal to y
  - 0b0010 when x is less than y
- cc: The 4-bit result compare code.

Explanation:

- –: The results do not depend on this condition.
- cc: The 4-bit result as defined in Table 66.
- error(): The system error handler is invoked for the trap-enabled exception if MSR.FE0 and MSR.FE1 are set to any mode other than the ignore-exception mode.
- fx[x]: FPSCR.FX is set to 1 if FPSCR.x=0. FPSCR.x is set to 1.
**VSX Scalar Compare Ordered Quad-Precision X-form**

```
xscmpoqp BF,VRA,VRB
```

```latex
\begin{array}{cccccc}
63 & 6 & BF & // & VRA & VRB & 132 \\
0 & 9 & 11 & 16 & 21 & 31
\end{array}
```

If either of the operands is a NaN, either quiet or signaling, CR field BF and the FPCC are set to reflect unordered. If either of the operands is a Signaling NaN, an Invalid Operation exception occurs and VXSNAN is set, and if Invalid Operation exceptions are disabled (VE=0), VXVC is set. If neither operand is a Signaling NaN but at least one operand is a Quiet NaN, an Invalid Operation exception occurs and VXVC is set.

**Special Registers Altered:**
- CR field BF
- FPSCR FX VXSNAN VXVC

Let src1 be the floating-point value in VSR[VRA+32] represented in quad-precision format.

Let src2 be the floating-point value in VSR[VRB+32] represented in quad-precision format.

src1 is compared to src2.

Zeros of same or opposite signs compare equal.
Infinities of same signs compare equal.

Bit 0 of CR field BF and FL are set to indicate if src1 is less than src2.

Bit 1 of CR field BF and FG are set to indicate if src1 is greater than src2.

Bit 2 of CR field BF and FE are set to indicate if src1 is equal to src2.

Bit 3 of CR field BF and FU are set to indicate unordered (i.e., src1 or src2 is a NaN).

\textbf{Programming Note}

This instruction can be used to operate on a single-precision source operand.

\textbf{Programming Note}

Previous versions of the architecture allowed the contents of words 1, 2, and 3 of the result register to be undefined, however, all processors that support this instruction write the result into both words 0 and 1 of the result register, as is required by this version of the architecture.

\textbf{Programming Note}

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

Let $XT$ be the value $32 \times TX + T$.
Let $XB$ be the value $32 \times BX + B$.

Let $src$ be the double-precision floating-point value in doubleword element 0 of $VSR[XB]$.

If $src$ is a SNaN, the result is $src$ converted to a QNaN (i.e., bit 12 of $src$ is set to 1). $VXSNAN$ is set to 1.

Otherwise, if $src$ is a QNaN, an Infinity, or a Zero, the result is $src$.

Otherwise, the result is $src$ rounded to single-precision using the rounding mode specified by RN.

The result is placed into word elements 0 and 1 of $VSR[XT]$ in single-precision format.

The contents of word elements 2 and 3 of $VSR[XT]$ are set to 0.

$FPRF$ is set to the class and sign of the result. $FR$ is set to indicate if the result was incremented when rounded. $FI$ is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, $VSR[XT]$ and $FPRF$ are not modified, and $FR$ and $FI$ are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 662.

\textbf{Special Registers Altered}

$FPRF$ $FR$ $FI$ $FX$ $OX$ $UX$ $XX$ $VXSNAN$

VSR[32×TX+T].word[1] ← result
VSR[32×TX+T].word[2] ← 0x0000_0000
VSR[32×TX+T].word[3] ← 0x0000_0000
```

Let **XT** be the value \(32\times TX + T\).
Let **XB** be the value \(32\times BX + B\).

Let **src** be the single-precision floating-point value in doubleword element 0 of VSR[**XB**] represented in double-precision format.

**src** is placed into word elements 0 and 1 of VSR[**XT**] in single-precision format.

The contents of word elements 2 and 3 of VSR[**XT**] are set to 0.

**Special Registers Altered**
None

**Programming Note**
If **x** is not representable in single-precision, some exponent and/or significand bits will be discarded, likely producing undesirable results. The low-order 29 bits of the significand of **x** are discarded, more if the unbiased exponent of **x** is less than -126 (i.e., denormal). Finite values of **x** having an unbiased exponent less than -150 will return a result of Zero. Finite values of **x** having an unbiased exponent greater than 127 will result in discarding significant bits of the exponent. SNaN inputs having no significant bits in the upper 23 bits of the significand will return Infinity as the result. No status is set for any of these cases.

**Programming Note**
**xscvdpsp** should be used to convert a scalar double-precision value to vector single-precision format.
**xscvdpspn** should be used to convert a scalar single-precision value to vector single-precision format.

**Programming Note**
See the Programming Note for the **xscvdpsp** instruction.

**Programming Note**
Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

Let XT be the value 32×TX + T.
Let XB be the value 32×BX + B.

Let src be the double-precision floating-point value in doubleword element 0 of VSR[XB].

If src is a NaN, the result is the value 0x8000_0000_0000_0000 and VXCVI is set to 1. If src is an NaN, VXSNAN is also set to 1.

Otherwise, src is rounded to a floating-point integer using the rounding mode Round Toward Zero.

If the rounded value is greater than 2^63-1, the result is 0x7FFF_FFFF_FFFF_FFFF and VXCVI is set to 1.

Otherwise, if the rounded value is less than -2^63, the result is 0x8000_0000_0000_0000 and VXCVI is set to 1.

Otherwise, the result is the rounded value converted to 64-bit signed-integer format, and if the result is inexact (i.e., not equal to src), XX is set to 1.

If a trap-enabled invalid operation exception occurs,
- VSR[XT] and FPRF are not modified
- FA and FI are set to 0.

Otherwise,
- The result is placed into doubleword element 0 of VSR[XT]. The contents of doubleword element 1 of VSR[XT] are set to 0.
- FPRF is set to an undefined value.
- FA is set to indicate if the result was incremented when rounded.
- FI is set to indicate the result is inexact.

See Table 70.

Note: This case cannot occur as Nmax is not representable in DP format but is included here for completeness.

**Explanation:**

- `error()` The system error handler is invoked for the trap-enabled exception if MSR.FE0 and MSR.FE1 bits are set to any mode other than the ignore-exception mode.
- `f2i(x)` The double-precision floating-point integer value x is converted to 64-bit signed integer format.
- `fi(x)` FPSCR.FI is set to the value x.
- `fr(x)` FPSCR.FR is set to the value x.
- `fx(x)` FPSCR.FX is set to 1 if FPSCR.x=0. FPSCR.x is set to 1.
- `Nmin` The smallest signed integer doubleword value, $-2^{63}$ (0x8000_0000_0000_0000).
- `Nmax` The largest signed integer doubleword value, $2^{63}-1$ (0x7FFF_FFFF_FFFF_FFFF).
- `src` The double-precision floating-point value in doubleword element 0 of VSR[XT]. The contents of doubleword element 1 of VSR[XT] are set to 0.
- `trunc(x)` The double-precision floating-point value x is truncated to a floating-point integer.
- `T(x)` The signed integer doubleword value x is placed in doubleword element 0 of VSR[XT]. The contents of doubleword element 1 of VSR[XT] are set to 0.

end

Let XT be the value 32×TX + T.

Let XB be the value 32×BX + B.

Let `src` be the double-precision floating-point value in doubleword element 0 of VSR[XB].

If `src` is a NaN, the result is the value 0x0000_0000_0000_0000 and VXCVI is set to 1. If `src` is an SNaN, VXSNAN is also set to 1.

Otherwise, `src` is rounded to a floating-point integer using the rounding mode Round Toward Zero.

If the rounded value is greater than 2^64 - 1, the result is 0xFFFF_FFFF_FFFF_FFFF and VXCVI is set to 1.

Otherwise, if the rounded value is less than 0, the result is 0x0000_0000_0000_0000 and VXCVI is set to 1.

Otherwise, the result is the rounded value converted to 64-bit unsigned-integer format, and if the result is inexact (i.e., not equal to `src`), XX is set to 1.

If a trap-enabled invalid operation exception occurs,

– VSX[XT] and FPRF are not modified
– FR and FI are set to 0.

Otherwise,

– The result is placed into doubleword element 0 of VSR[XT]. The contents of doubleword element 1 of VSR[XT] are set to 0.
– FPRF is set to an undefined value.
– FR is set to indicate if the result was incremented when rounded.
– FI is set to indicate the result is inexact.

See Table 72.

Special Registers Altered

FPRF=0bUUUUU FR FI FX XX VXSNAN VXCVI

Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

`xscvdpuxds` rounds using Round towards Zero rounding mode. For other rounding modes, software must use a Round to Double-Precision Integer instruction that corresponds to the desired rounding mode, including `xsrdpic` which uses the rounding mode specified by RN.

Programming Note

This instruction can be used to operate on a single-precision source operand.

|              | 1 | - | - | T(Nmin), fr(0), fi(0), fx(VXCVI), fx(VXSNAN), error() |

| src is a SNaN | 0 | - | - | T(Nmin), fr(0), fi(0), fx(VXCVI), fx(VXSNAN) |
|              | 1 | - | - | T(Nmin), fr(0), fi(0), fx(VXCVI), fx(VXSNAN), error() |

**Explanation:**

- **error()**  
  The system error handler is invoked for the trap-enabled exception if MSR.FE0 and MSR.FE1 are set to any mode other than the ignore-exception mode.

- **f2i(x)**  
  The double-precision floating-point integer value x is converted to a 64-bit unsigned integer format.

- **fi(x)**  
  FPSCR.FI is set to the value x.

- **fr(x)**  
  FPSCR.FR is set to the value x.

- **fx(x)**  
  FPSCR.FX is set to 1 if FPSCR.x=0. FPSCR.x is set to 1.

- **Nmin**  
  The smallest unsigned integer doubleword value, \(0x0000_0000_0000_0000\).

- **Nmax**  
  The largest unsigned integer doubleword value, \(2^{64}-1\) (\(0x{FFFF_FFFF_FFFF_FFFF}\)).

- **src**  
  The double-precision floating-point value in doubleword element 0 of VSR[XB].

- **trunc(x)**  
  The double-precision floating-point value x is truncated to a floating-point integer.

- **T(x)**  
  The unsigned integer doubleword value x is placed in doubleword element 0 of VSR[XT]. The contents of doubleword element 1 of VSR[XT] are set to 0.

FPSCR.FI ← 0b0
end

Let XT be the value 32×TX + T.
Let XB be the value 32×BX + B.

Let src be the double-precision floating-point value in doubleword element 0 of VSR[XB].

If src is a NaN, the result is the value 0x0000_0000 and VXCVI is set to 1. If src is an SNaN, VXSNAN is also set to 1.

Otherwise, src is rounded to a floating-point integer using the rounding mode Round Toward Zero.

If the rounded value is greater than 2^32-1, the result is 0xFFFF_FFFF and VXCVI is set to 1.

Otherwise, if the rounded value is less than 0, the result is 0x0000_0000 and VXCVI is set to 1.

Otherwise, the result is the rounded value converted to 32-bit unsigned-integer format, and if the result is inexact (i.e., not equal to src), XX is set to 1.

If a trap-enabled invalid operation exception occurs,
- VSR[XT] and FPRF are not modified
- FR and FI are set to 0.

Otherwise,
- The result is placed into word elements 0 and 1 of VSR[XT]. The contents of word elements 2 and 3 of VSR[XT] are set to 0.
- FPRF is set to an undefined value.
- FR is set to indicate if the result was incremented when rounded.
- FI is set to indicate the result is inexact.

See Table 73.

**Special Registers Altered**

FPRF=0bUUUUU FR FI FX XX VXSNAN VXCVI

**Programming Note**

Previous versions of the architecture allowed the contents of word 0 of the result register to be undefined. However, all processors that support this instruction write the result into words 0 and 1 of the result register, as is required by this version of the architecture.

**Programming Note**

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

**Programming Note**

This instruction can be used to operate on a single-precision source operand.

**Programming Note**

xscvdpuxws rounds using Round towards Zero rounding mode. For other rounding modes, software must use a Round to Double-Precision Integer instruction that corresponds to the desired rounding mode, including xsrdpic which uses the rounding mode specified by RN.

\end{verbatim}

Let \( src \) be the quad-precision floating-point value in \( VSR[VRB+32] \).

If \( src \) is a Signalling NaN, an Invalid Operation exception occurs and \( VXSNAN \) is set to 1.

If \( src \) is a Signalling NaN, the result is the Quiet NaN corresponding to the Signalling NaN, with the significand truncated to the rounding precision.

Otherwise, if \( src \) is a Quiet NaN, then the result is \( src \) with the significand truncated to the double-precision.

Otherwise, if \( src \) is an Infinity or a Zero, the result is \( src \).

The result is placed into doubleword element 0 of \( VSR[VRT+32] \) in double-precision format. The contents of doubleword element 1 of \( VSR[VRT+32] \) are set to 0.

\( FPRF \) is set to the class and sign of the result as represented in double-precision format. \( FR \) is set to indicate if the rounded result was incremented. \( FI \) is set to indicate the result is inexact.

If a trap-disabled Invalid Operation exception occurs, \( FR \) and \( FI \) are set to 0.

If a trap-enabled Invalid Operation exception occurs, \( VSR[VRT+32] \) and \( FPRF \) are not modified, and \( FR \) and \( FI \) are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 662.

Special Registers Altered:
\( FPRF \ FR \ FI \ FX \ VXSNAN \ OX \ UX \ XX \)
Let `src` be the quad-precision floating-point value in `VSR[VRB+32]`.

If `src` is a Signalling NaN, an Invalid Operation exception occurs and `VXSNAN` and `VXCVI` are set to 1.

If `src` is a Quiet NaN or an Infinity, an Invalid Operation exception occurs and `VXCVI` is set to 1.

If `src` is a NaN, the result is `0x8000_0000_0000_0000`.

Otherwise, if `src` is a Zero, the result is `0x0000_0000_0000_0000`.

Otherwise, if `src` is `-Infinity`, the result is `0x7FFF_FFFF_FFFF_FFFF`.

Otherwise, if `src` is `-Infinity`, the result is `0x8000_0000_0000_0000`.

Otherwise, do the following.

Let `rnd` be the value `src` truncated to a floating-point integer.

If `rnd` is greater than `+2^{63}-1`, an Invalid Operation exception occurs, `VXCVI` is set to 1, and the result is `0x7FFF_FFFF_FFFF_FFFF`.

Otherwise, if `rnd` is less than `-2^{63}`, an Invalid Operation exception occurs, `VXCVI` is set to 1, and the result is `0x8000_0000_0000_0000`.

Otherwise, the result is the value `rnd`, and an Inexact exception occurs if `rnd` is inexact (i.e., `rnd` is not equal to `src`).

The result is placed into doubleword element 0 of `VSR[VRT+32]` in signed integer format.

The contents of doubleword element 1 of `VSR[VRT+32]` are set to 0.

`FPRF` is set to undefined. `FR` is set to 0. `FI` is set to indicate if the rounded result is inexact.

If an Invalid Operation exception occurs, `FR` and `FI` are set to 0.

If a trap-enabled Invalid Operation exception occurs, `VSR[VRT+32]` and `FPRF` are not modified.

See Table 70, “Actions for xscvdpsxds,” on page 688.

Explanation:

- **T(x)**: Places the value x into the target VSR.
  
- **VSR[VRB+32], dword[0]**: x

- **trunc(x)**: Return the quad-precision floating-point value x truncated to a floating-point integer.

- **fp2i(x)**: The quad-precision floating-point integer value x is converted to 64-bit signed integer format.

- **fp(x)**: The largest signed integer doubleword value, \(2^{63} \times (0x7FFF_FFFF_FFFF_FFFF)\).

- **fp(x)**: The smallest signed integer doubleword value, \(-2^{63} \times (0x8000_0000_0000_0000)\).

- **src**: The quad-precision floating-point value in VSR[VRB+32].

- **fi(x)**: FPSCR.FI is set to the value x.

- **fr(x)**: FPSCR.FR is set to the value x.

- **fprf(x)**: FPSCR.FPRF is set to the value x.

- **fx(x)**: FPSCR.FX is set to the value x.

- **error()**: The system error handler is invoked for the trap-enabled exception if MSR.FE0 and MSR.FE1 are set to any mode other than the ignore-exception mode.

Table 74. Actions for xscvqpsdz
Let \( src \) be the quad-precision floating-point value in \( VSR[VRB+32] \).

If \( src \) is a Signalling NaN, an Invalid Operation exception occurs and \( VXSNAN \) and \( VXCVI \) are set to 1.

If \( src \) is a Quiet NaN or an Infinity, an Invalid Operation exception occurs and \( VXCVI \) is set to 1.

If \( src \) is a NaN, the result is \(-2^{127}\).

Otherwise, if \( src \) is a Zero, the result is 0.

Otherwise, if \( src \) is +Infinity, the result is \( 2^{127}-1 \).

Otherwise, if \( src \) is -Infinity, the result is \(-2^{127}\).

Otherwise, do the following.

Let \( \text{rnd} \) be the value \( src \) truncated to a floating-point integer.

If \( \text{rnd} \) is greater than \(+2^{127}-1\), an Invalid Operation exception occurs, \( VXCVI \) is set to 1, and the result is \( 2^{127} \).

Otherwise, if \( \text{rnd} \) is less than \(-2^{127}\), an Invalid Operation exception occurs, \( VXCVI \) is set to 1, and the result is \(-2^{127}\).

Otherwise, the result is the value \( \text{rnd} \), and an Inexact exception occurs if \( \text{rnd} \) is inexact (i.e., \( \text{rnd} \) is not equal to \( src \)).

The result is placed into doubleword element 0 of \( VSR[VRT+32] \) in signed integer format.

The contents of doubleword element 1 of \( VSR[VRT+32] \) are set to 0.

\( FPRF \) is set to undefined. \( FR \) is set to 0. \( FI \) is set to indicate if the rounded result is inexact.

If an Invalid Operation exception occurs, \( FR \) and \( FI \) are set to 0.

If a trap-enabled Invalid Operation exception occurs, \( VSR[VRT+32] \) and \( FPRF \) are not modified.

See Table 75, “Actions for xscvqpsqz,” on page 700.

Special Registers Altered:

- \( FPRF \) (undefined)
- \( FR \) (set to 0)
- \( FI \)
- \( VXSNAN\)
- \( VXCVI\)
- \( XX\)

 | 1 | - \( T(N_{max}), f(0), f(0), fx(VXCVI), e(0) \)
src is a QNaN | 0 | - \( T(N_{min}), f(0), f(0), fprf(0bUUUUU), fx(VXCVI), f(0) \)
 | 1 | - \( T(N_{min}), f(0), f(0), fx(VXCVI), f(0), e(0) \)
src is a SNaN | 0 | - \( T(N_{min}), f(0), f(0), fprf(0bUUUUU), fx(VXCVI), f(0), fx(VXSNAN) \)
 | 1 | - \( T(N_{min}), f(0), f(0), fx(VXCVI), f(0), fx(VXSNAN), e(0) \)

**Explanation:**
- \( T(x) \) Places the value \( x \) into the target VSR.
- \( N_{min} \) The smallest signed integer doubleword value, \(-2^{127} \cdot 0x8000_0000_0000_0000_0000_0000_0000_0000\).
- \( N_{max} \) The largest signed integer doubleword value, \( 2^{127-1} \cdot (0x7FFF_FFFF_FFFF_FFFF_FFFF_FFFF_FFFF_FFFF) \).
- \( src \) The quad-precision floating-point value in VSR[VRB+32].
- \( \{2\cdot\text{trunc}(x)\} \) The quad-precision floating-point integer value \( x \) is converted to 128-bit signed integer format.
- \( f(x) \) FPSCR.\( FX \) is set to 1 if FPSCR.\( x \) = 1. FPSCR.\( x \) is set to 1.
- \( f(x) \) FPSCR.\( FI \) is set to the value \( x \).
- \( f(x) \) FPSCR.\( FX \) is set to the value \( x \).
- \( fprf(x) \) FPSCR.\( FPRF \) is set to the value \( x \).
- \( error() \) The system error handler is invoked for the trap-enabled exception if MSR.\( FE0 \) and MSR.\( FE1 \) are set to any mode other than the ignore-exception mode.
- \( \text{trunc}(x) \) Returns the floating-point value \( x \) truncated to a floating-point integer.

Let src be the quad-precision floating-point value in VSR[VRT+32].

If src is a Signalling NaN, an Invalid Operation exception occurs and VXSNAN and VXCVI are set to 1.

If src is a Quiet NaN or an Infinity, an Invalid Operation exception occurs and VXCVI is set to 1.

If src is a NaN, the result is 0xFFFF_FFFF_8000_0000.

Otherwise, if src is a Zero, the result is 0x0000_0000_0000_0000.

Otherwise, if src is a +Infinity, the result is 0x0000_0000_7FFF_FFFF.

Otherwise, if src is a -Infinity, the result is 0xFFFF_FFFF_8000_0000.

Otherwise, do the following.
Let rnd be the value src truncated to a floating-point integer.

If rnd is greater than +231-1, an Invalid Operation exception occurs, VXCVI is set to 1, and the result is 0x0000_0000_7FFF_FFFF.

Otherwise, if rnd is less than -231, an Invalid Operation exception occurs, VXCVI is set to 1, and the result is 0xFFFF_FFFF_8000_0000.

Otherwise, the result is the value rnd, and an Inexact exception occurs if rnd is inexact (i.e., rnd is not equal to src).

The result is placed into doubleword element 0 of VSR[VRT+32] in signed integer format.

The contents of doubleword element 1 of VSR[VRT+32] are set to 0.

FPRF is set to undefined. FR is set to 0. FI is set to indicate if the rounded result is inexact.

If an Invalid Operation exception occurs, FR and FI are set to 0.

If a trap-enabled Invalid Operation exception occurs, VSR[VRT+32] and FPRF are not modified.

See Table 76, “Actions for xscvqp swz,” on page 702.

VSR Data Layout for xscvqpuz

Let \( src \) be the quad-precision floating-point value in \( VSR[VRB+32] \).

If \( src \) is a Signalling NaN, an Invalid Operation exception occurs and \( VXSNAN \) and \( VXCVI \) are set to 1.

If \( src \) is a Quiet NaN or an Infinity, an Invalid Operation exception occurs and \( VXCVI \) is set to 1.

If \( src \) is a NaN, the result is 0.

Otherwise, if \( src \) is a Zero, the result is 0.
Otherwise, if \( src \) is \( +\)Infinity, the result is \( 2^{128} - 1 \).
Otherwise, if \( src \) is \( -\)Infinity, the result is 0.

Otherwise, do the following.

Let \( \text{rnd} \) be the value \( src \) truncated to a floating-point integer.

If \( \text{rnd} \) is greater than \( 2^{128} - 1 \), an Invalid Operation exception occurs, \( VXCVI \) is set to 1, and the result is \( 2^{128} - 1 \).

Otherwise, if \( \text{rnd} \) is less than 0, an Invalid Operation exception occurs, \( VXCVI \) is set to 1, and the result is 0.

Otherwise, the result is the value \( \text{rnd} \), and an Inexact exception occurs if \( \text{rnd} \) is inexact (i.e., \( \text{rnd} \) is not equal to \( src \)).

The result is placed into \( VSR[VRT+32] \) in unsigned integer format.

\( \text{FPRF} \) is set to undefined. \( \text{FR} \) is set to 0. \( \text{FI} \) is set to indicate if the rounded result is inexact.

If an Invalid Operation exception occurs, \( \text{FR} \) and \( \text{FI} \) are set to 0.

If a trap-enabled Invalid Operation exception occurs, \( VSR[VRT+32] \) and \( \text{FPRF} \) are not modified.

See Table 77, “Actions for xscvqpudz,” on page 704.

Special Registers Altered:
\[
\begin{align*}
\text{FPRF} & \quad \text{(undefined)} \\
\text{FR} & \quad \text{(set to 0)} \\
\text{FI} & \quad \text{( lessen if the rounded result is inexact)}
\end{align*}
\]

If an Invalid Operation exception occurs, \( \text{FR} \) and \( \text{FI} \) are set to 0.

If a trap-enabled Invalid Operation exception occurs, \( VSR[VRT+32] \) and \( \text{FPRF} \) are not modified.

See Table 77, “Actions for xscvqpudz,” on page 704.

Special Registers Altered:
\[
\begin{align*}
\text{FPRF} & \quad \text{(undefined)} \\
\text{FR} & \quad \text{(set to 0)} \\
\text{FI} & \quad \text{(lessen if the rounded result is inexact)}
\end{align*}
\]

If an Invalid Operation exception occurs, \( \text{FR} \) and \( \text{FI} \) are set to 0.

If a trap-enabled Invalid Operation exception occurs, \( VSR[VRT+32] \) and \( \text{FPRF} \) are not modified.

#### Explanation:

- **T(x)** Places the value `x` into the target VSR.
- **Nmin** The smallest unsigned integer doubleword value, `0x0000_0000_0000_0000_0000_0000_0000_0000`.
- **Nmax** The largest unsigned integer doubleword value, `0x7FFF_7FFF_7FFF_7FFF_7FFF_7FFF_7FFF_7FFF`.
- **f2i(x)** The quad-precision floating-point integer value `x` is converted to 128-bit unsigned integer format.
- **fx** FPSCR.FX is set to 1 if FPSCR.xF = 0.
- **fi** FPSCR.FI is set to the value `x`.
- **fr** FPSCR.FR is set to the value `x`.
- **fprf** FPSCR.FPRF is set to the value `x`.
- **error()** The system error handler is invoked for the trap-enabled exception if MSR.FE0 and MSR.FE1 are set to any mode other than the ignore-exception mode.
- **trunc(x)** Return the floating-point value `x` truncated to a floating-point integer.

### Table 78. Actions for `xscvqpuqz`
Let \( \text{src} \) be the quad-precision floating-point value in \( VSR[VRB+32] \).

If \( \text{src} \) is a Signalling NaN, an Invalid Operation exception occurs and \( VXSNAN \) and \( VXCVI \) are set to 1.

If \( \text{src} \) is a Quiet NaN or an Infinity, an Invalid Operation exception occurs and \( VXCVI \) is set to 1.

If \( \text{src} \) is a NaN, the result is \( 0x0000_0000_0000_0000 \).

Otherwise, if \( \text{src} \) is a Zero, the result is \( 0x0000_0000_0000_0000 \).

Otherwise, if \( \text{src} \) is a positive Infinity, the result is \( 0x0000_0000_FFFF_FFFF \).

Otherwise, do the following.

Let \( \text{rnd} \) be the value \( \text{src} \) truncated to a floating-point integer.

If \( \text{rnd} \) is greater than \( +2^{32}-1 \), an Invalid Operation exception occurs and \( VXCVI \) is set to 1, and the result is \( 0x0000_0000_FFFF_FFFF \).

Otherwise, if \( \text{rnd} \) is less than 0, an Invalid Operation exception occurs, \( VXCVI \) is set to 1, and the result is \( 0x0000_0000_0000_0000 \).

Otherwise, the result is the value \( \text{rnd} \), and an Inexact exception occurs if \( \text{rnd} \) is inexact (i.e., \( \text{rnd} \) is not equal to \( \text{src} \)).

The result is placed into doubleword element 0 of \( VSR[VRT+32] \) in unsigned integer format.

The contents of doubleword element 1 of \( VSR[VRT+32] \) are set to 0.

\( FPRF \) is set to undefined. \( FR \) is set to 0. \( FI \) is set to indicate if the rounded result is inexact.

If an Invalid Operation exception occurs, \( FR \) and \( FI \) are set to 0.

If a trap-enabled Invalid Operation exception occurs, \( VSR[VRT+32] \) and \( FPRF \) are not modified.

**Special Registers Altered:**

\[ FPRF \text{ (undefined)} \quad FR \text{ (set to 0)} \quad FI \]

\[ FX VXSNAN VXCVI XX \]

#### Explanation:

- **T(x)**: Places the value x into the target VSR.
  - `VSR[VRT+32], dword[0] = x`
  - `VSR[VRT+32], dword[1] = 0x0000_0000_0000_0000`

- **Nmin**: The smallest unsigned integer word value, 0 (0x0000_0000_0000_0000).
- **Nmax**: The largest unsigned integer word value, 2\(^{32}\) - 1 (0x0000_0000_FFFF_FFFF).
- **src**: The quad-precision floating-point value in VSR[VRB+32].
- **f2i(x)**: The quad-precision floating-point integer value x is converted to 32-bit unsigned integer format.
- **fx(x)**: FPSCR.FX is set to 1 if FPSCR.x=0. FPSCR.x is set to 1.
- **fr(x)**: FPSCR.FR is set to the value x.
- **fprf(x)**: FPSCR.FPRF is set to the value x.
- **error()**: The system error handler is invoked for the trap-enabled exception if MSR.FE0 and MSR.FE1 are set to any mode other than the ignore-exception mode.
- **trunc(x)**: Return the floating-point value x truncated to a floating-point integer.

</tr>
</tbody>
</table>

**Explanation:**
src1 The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2 The double-precision floating-point value in doubleword element 0 of VSR[XB].
dQNaN Default quiet NaN (0x7FF8_0000_0000_0000).
NZF Nonzero finite number.
D(x,y) Return the normalized quotient of floating-point value x divided by floating-point value y, having unbounded range and precision.
Q(x) Return a QNaN with the payload of x.
v The intermediate result having unbounded significand precision and unbounded exponent range.
**VSX Scalar Divide Quad-Precision [using round to Odd] X-form**

Let src1 be the floating-point value in VSR[VRA+32] represented in quad-precision format.

Let src2 be the floating-point value in VSR[VRB+32] represented in quad-precision format.

If either src1 or src2 is a Signalling NaN, an Invalid Operation exception occurs and VXSNAN is set to 1.

If src1 and src2 are Infinity values, an Invalid Operation exception occurs and VXI DI is set to 1.

If src1 and src2 are Zero values, an Invalid Operation exception occurs and VXZDZ is set to 1.

If src1 is a finite value and src2 is a Zero value, an Zero Divide exception occurs and VXZ is set to 1.

If src1 is a Signalling NaN, the result is the Quiet NaN corresponding to src1.

Otherwise, if src1 is a Quiet NaN, the result is src1.

Otherwise, if src2 is a Signalling NaN, the result is the Quiet NaN corresponding to src2.

Otherwise, if src1 is a Quiet NaN, the result is src2.

Otherwise, if src1 and src2 are Infinity values, or if src1 and src2 are Zero values, the result is the default Quiet NaN[1].

Otherwise, if src1 is a non-zero value and src2 is a Zero value, the result is an Infinity.

Otherwise, do the following.

The normalized quotient of src1 divided by src2 is produced with unbounded significand precision and exponent range.

See Table 81, “Actions for xsdivqp[0],” on page 720.

If the intermediate result is Tiny (i.e., the unbiased exponent is less than -16382) and UE=0, the significand is shifted right N bits, where N is the difference between -16382 and the unbiased exponent of the intermediate result. The exponent of the intermediate result is set to the value -16382.

If RO=1, let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by RN. Unless the result is an Infinity or a Zero, the intermediate result is rounded to quad-precision using the specified rounding mode.

The result is placed into VSR[VRT+32] in quad-precision format.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-disabled Invalid Operation exception occurs, FR and FI are set to 0.

If a trap-disabled Zero Divide exception occurs, FR and FI are set to 0.

If a trap-enabled Invalid Operation exception or a trap-enabled Zero Divide exception occurs, VSR[VRT+32] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 662.

---

1. The quad-precision default Quiet NaN is the value, 0x7FFF_8000_0000_0000_0000_0000_0000.

**Explanation:**

- **src1**: The quad-precision floating-point value in VSR[ VRA+32].
- **src2**: The quad-precision floating-point value in VSR[ VRB+32].
- **qNaN**: Default quiet NaN (0x7FFF_8000_0000_0000_0000_0000_0000_0000).
- **NZF**: Nonzero finite number.
- **De(x, y)**: The floating-point value x is divided by floating-point value y. Return the normalized quotient, having unbounded range and precision.
- **quiet(x)**: Convert x to the corresponding Quiet NaN.
- **v**: The intermediate result having unbounded significand precision and unbounded exponent range.

**Table 81. Actions for xsdivqp[o]**

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then subtracted or added as appropriate, depending on the signs of the operands, to form an intermediate difference. All 64 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

VSR Data Layout for xsiexpqp

\begin{verbatim}
src1
\end{verbatim}

\begin{verbatim}
src2
\end{verbatim}

\begin{verbatim}
tgt
\end{verbatim}
Let $X_A$ be the value $32 \times X + A$.
Let $X_B$ be the value $32 \times X + B$.

Let $src_1$ be the double-precision floating-point value in doubleword element 0 of $VSR[X_A]$.

For $xsmaddadp$, do the following.
- Let $src_2$ be the double-precision floating-point value in doubleword element 0 of $VSR[X_T]$.
- Let $src_3$ be the double-precision floating-point value in doubleword element 0 of $VSR[X_B]$.

For $xsmaddmdp$, do the following.
- Let $src_2$ be the double-precision floating-point value in doubleword element 0 of $VSR[X_B]$.
- Let $src_3$ be the double-precision floating-point value in doubleword element 0 of $VSR[X_T]$.

$src_1$ is multiplied\(^1\) by $src_3$, producing a product having unbounded range and precision.

See part 1 of Table 83.

$src_2$ is added\(^2\) to the product, producing a sum having unbounded range and precision.

The sum is normalized\(^3\).

See part 2 of Table 83.

The intermediate result is rounded to double-precision using the rounding mode specified by $RN$.

The result is placed into doubleword element 0 of $VSR[X_T]$ in double-precision format.

The contents of doubleword element 1 of $VSR[X_T]$ are set to 0.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, $VSR[X_T]$ and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 662.

| 60 T A B 33 AX BX TX | 0 6 11 16 21 29 30 31 | 60 T A B 41 AX BX TX | 0 6 11 16 21 29 30 31

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.
Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

**Explanation:**
- src1: The double-precision floating-point value in doubleword element 0 of VSR[XA].
- src2: For xsmaddadp, the double-precision floating-point value in doubleword element 0 of VSR[XT].
- src3: For xsmadda, the double-precision floating-point value in doubleword element 0 of VSR[XB].
- dQNaN: Default quiet NaN (0x7FF8_0000_0000_0000).
- NZF: Nonzero finite number.
- Rezd: Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
- Q(x): Return a QNaN with the payload of x.
- A(x,y): Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision. Note: If x = -y, v is considered to be an exact-zero-difference result (Rezd).
- M(x,y): Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
- p: The intermediate product having unbounded range and precision.
- v: The intermediate result having unbounded range and precision.
VSX Scalar Multiply-Add Type-A
Single-Precision XX3-form

\[
x_{\text{smaddasp}} \quad X_T, X_A, X_B
\]

Let \(X_T\) be the value \(32 \times X_T + T\).
Let \(X_A\) be the value \(32 \times X_A + A\).
Let \(X_B\) be the value \(32 \times X_B + B\).

For \(x_{\text{smaddasp}}\), do the following.

– Let \(src1\) be the double-precision floating-point value in doubleword element 0 of \(VSR[X_A]\).
– Let \(src2\) be the double-precision floating-point value in doubleword element 0 of \(VSR[X_T]\).
– Let \(src3\) be the double-precision floating-point value in doubleword element 0 of \(VSR[X_B]\).

For \(x_{\text{smaddmsp}}\), do the following.

– Let \(src1\) be the double-precision floating-point value in doubleword element 0 of \(VSR[X_A]\).
– Let \(src2\) be the double-precision floating-point value in doubleword element 0 of \(VSR[X_B]\).
– Let \(src3\) be the double-precision floating-point value in doubleword element 0 of \(VSR[X_T]\).

\(src1\) is multiplied\(^{[1]}\) by \(src3\), producing a product having unbounded range and precision.

See part 1 of Table 84, “Actions for \(x_{\text{smadd}(a|m)sp}\),” on page 730.

\(src2\) is added\(^{[2]}\) to the product, producing a sum having unbounded range and precision.

The sum is normalized\(^{[3]}\).

See part 2 of Table 84, “Actions for \(x_{\text{smadd}(a|m)sp}\),” on page 730.

The intermediate result is rounded to single-precision using the rounding mode specified by \(RN\).

The result is placed into doubleword element 0 of \(VSR[X_T]\) in double-precision format.

The contents of doubleword element 1 of \(VSR[X_T]\) are set to 0.

\(FPFR\) is set to the class and sign of the result as represented in single-precision format. \(FR\) is set to indicate if the result was incremented when rounded. \(FI\) is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, \(VSR[X_T]\) and \(FPFR\) are not modified, and \(FR\) and \(FI\) are set to 0.

---

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

\end{array}
\]

if MSR.VSX=0 then VSX_Unavailable() reset_xflags() src1 ← bfp_CONVERT_FROM_BFP128(VSR[VRA+32]) src2 ← bfp_CONVERT_FROM_BFP128(VSR[VRT+32]) src3 ← bfp_CONVERT_FROM_BFP128(VSR[VRB+32]) v ← bfp_MULTIPLY_ADD(src1, src3, src2) rnd ← bfp_ROUND_TO_BFP128(RD, FPSCR.RN, v) result ← bfp128_CONVERT_FROM_BFP(rnd) if vxsnan_flag=1 then SetFX(FPSCR.VXSNAN) if vximz_flag=1 then SetFX(FPSCR.VXIMZ) if vxisi_flag=1 then SetFX(FPSCR.VXISI) if ox_flag=1 then SetFX(FPSCR.OX) if ux_flag=1 then SetFX(FPSCR.UX) if xx_flag=1 then SetFX(FPSCR.XX) vx_flag ← vxsnan_flag | vximz_flag | vxisi_flag ex_flag ← FPSCR.VE & vx_flag if ex_flag=0 then do VSR[VRT+32] ← result FPSCR.FPREF ← fprf_CLASS_BFP128(result) end FPSCR.FR ← (vx_flag=0) & inc_flag FPSCR.FI ← (vx_flag=0) & xx_flag

Let src1 be the floating-point value in VSR[VRA+32] represented in quad-precision format.

Let src2 be the floating-point value in VSR[VRT+32] represented in quad-precision format.

Let src3 be the floating-point value in VSR[VRB+32] represented in quad-precision format.

If either src1, src2, or src3 is a Signalling NaN, an Invalid Operation exception occurs and VXSNAN is set to 1.

If src1 is an Infinity value and src3 is a Zero value, or if src1 is a Zero value and src3 is an Infinity value, an Invalid Operation exception occurs and VXIMZ is set to 1.

If src2 and the product of src1 and src3 are Infinity values having opposite signs, an Invalid Operation exception occurs and VXISI is set to 1.

If src1 is a Signalling NaN, the result is the Quiet NaN corresponding to src1.

Otherwise, if src1 is a Quiet NaN, the result is src1.

Otherwise, if src2 is a Signalling NaN, the result is the Quiet NaN corresponding to src2.

Otherwise, if src2 is a Quiet NaN, the result is src2.

Otherwise, if src3 is a Signalling NaN, the result is the Quiet NaN corresponding to src3.

Otherwise, if src3 is a Quiet NaN, the result is src3.

Otherwise, if src1 is an Infinity value and src3 is a Zero value, or if src1 is a Zero value and src3 is an Infinity value, the result is the default Quiet NaN[1].

Otherwise, if the product of src1 and src3, and src2 are Infinity values having opposite signs, the result is the default Quiet NaN.

Otherwise, do the following. src1 is multiplied by src3, producing a product having unbonded significand precision and exponent range.

See part 1 of Table 83. "Actions for xsmadd(a|m)dp".

src2 is added to the product, producing a sum having unbonded range and precision.

See part 2 of Table 83. "Actions for xsmadd(a|m)dp".

If the intermediate result is Tiny (i.e., the unbiased exponent is less than \(-16382\)) and UE=0, the significand is shifted right \(N\) bits, where \(N\) is the difference between \(-16382\) and the unbiased exponent of the intermediate result. The exponent of the intermediate result is set to the value \(-16382\). If RO=1, let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by RN. Unless the result is an Infinity or a Zero, the intermediate result is rounded to quad-precision using the specified rounding mode.

The result is placed into VSR[VRT+32] in quad-precision format.

FPREF is set to the class and sign of the result. FR is set to indicate if the rounded result was incremented. FI is set to indicate the result is inexact.

---

1. The quad-precision default Quiet NaN is the value, 0x7FFF_8000_0000_0000_0000_0000_0000_0000.
If a trap-disabled Invalid Operation exception occurs, FR and FI are set to 0.

If a trap-enabled Invalid Operation exception occurs, VSR[VRT+32] and FPREF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 662.

**vxsnan_flag** ← 1

**vxisi_flag** ← 1

**vximz_flag** ← 1

**Explanation:**
- **src1** The quad-precision floating-point value in VSR[VR(A+32)].
- **src2** The quad-precision floating-point value in VSR[VR(T+32)].
- **src3** The quad-precision floating-point value in VSR[VR(B+32)].
- **dQNaN** Default quiet NaN (0x7FFF_8000_0000_0000_0000_0000_0000).
- **NZF** Nonzero finite number.
- **Rezd** Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
- **quiet(x)** Return a QNaN with the payload of x.
- **add(x, y)** Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision. Note: If x = -y, v is considered to be an exact-zero-difference result (Rezd).
- **mul(x, y)** Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
- **p** The intermediate product having unbounded range and precision.
- **v** The intermediate result having unbounded range and precision.

**Table 85. Actions for xsmaddpq[o]**

**xsmaxdp**

|  |  |  |  |  |  |  |  |  |
|---|---|---|---|---|---|---|---|
| 0 | 60 | T | A | B | 160 | VSR[XA] | 128 |

if MSR.VSX=0 then VSX_Unavailable();

reset_xflags();

src1 ← VSR[32×AX+A].dword[0]

src2 ← VSR[32×BX+B].dword[0]

result ← bfpmu_maxnum(src1, src2)

if vxsnan_flag=1 then SetFX(FPSCR.VXSNAN)

vex_flag ← FPSCR.VE & vxsnan_flag

if vex_flag=0 then do

VSR[32×TX+T].dword[0] ← result

VSR[32×TX+T].dword[1] ← 0x0000_0000_0000_0000

don end

Let XT be the value 32×TX + T.

Let XA be the value 32×AX + A.

Let XB be the value 32×BX + B.

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

If src1 is greater than src2, src1 is placed into doubleword element 0 of VSR[XT]. Otherwise, src2 is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

The maximum of +0 and -0 is +0. The maximum of a QNaN and any value is that value. The maximum of any value and an SNaN is that SNaN converted to a QNaN.

FPFR, FR and FI are not modified.

If a trap-enabled invalid operation exception occurs, VSR[XT] is not modified.

See Table 86.

### Explanation:

- **src1**: The double-precision floating-point value in doubleword element 0 of `VSR[XA].`
- **src2**: The double-precision floating-point value in doubleword element 0 of `VSR[XT].`
- **NZF**: Nonzero finite number.
- **M(x, y)**: Return the greater of floating-point value x and floating-point value y.
- **T(x)**: The value x is placed in doubleword element 0 of `VSR[XT]` in double-precision format. The contents of doubleword element 1 of `VSR[XT]` are set to 0.
- **FX**: FPRF, FR, and FI are not modified.
- **fx(x)**: If x is equal to 0, FX is set to 1. x is set to 1.
- **VXSNAN**: Floating-Point Invalid Operation Exception (SNaN) status flag, VXSNAN. If VE = 1, update of `VSR[XT]` is suppressed.
**VSX Scalar Minimum Double-Precision XX3-form**

```plaintext
xsmindp XT,XA,XB

let XT be the value 32×TX + T.
let XA be the value 32×AX + A.
let XB be the value 32×BX + B.

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].
Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

If src1 is less than src2, src1 is placed into doubleword element 0 of VSR[XT] in double-precision format.
Otherwise, src2 is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

The minimum of +0 and –0 is –0. The minimum of a QNaN and any value is that value. The minimum of any value and an SNaN is that SNaN converted to a QNaN.

FPRF, FR and FI are not modified.

If a trap-enabled invalid operation exception occurs, VSR[XT] is not modified.

See Table 90.

**Special Registers Altered**

| FX | VXSNAN |

**Programming Note**

This instruction can be used to operate on single-precision source operands.

**Programming Note**

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

end

Let XT be the value 32×T + T.
LetXA be the value 32×A + A.
LetXB be the value 32×B + B.

Let src1 be the double-precision floating-point value in doubleword 0 of VSR[XA].
Let src2 be the double-precision floating-point value in doubleword 0 of VSR[XB].

If src1 or src2 is a SNaN, an Invalid Operation exception occurs.
If either src1 or src2 is a NaN, result is src2.
Otherwise, if src1 is less than src2, result is src1.
Otherwise, result is src2.

The contents of doubleword 0 of VSR[XT] are set to the value result.
The contents of doubleword 1 of VSR[XT] are set to 0.

If a trap-enabled Invalid Operation occurs, VSR[XT] is not modified.

**Special Registers Altered:**
FX VXSNAN

---

**Programming Note**

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.
See Table 63, “VSX Scalar Floating-Point Final Result,” on page 662.

#### Explanation:

- **src1**: The double-precision floating-point value in doubleword element 0 of VSR[XA].
- **src2**: For `xmsubdp`, the double-precision floating-point value in doubleword element 0 of VSR[XT].
- **src3**: For `xmsubdp`, the double-precision floating-point value in doubleword element 0 of VSR[XB].
- **dQNaN**: Default quiet NaN (0x7FF8_0000_0000_0000).
- **NZF**: Nonzero finite number.
- **Rezd**: Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
- **Q(x)**: Return a QNaN with the payload of x.
- **S(x,y)**: Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision.
  - Note: If x = y, v is considered to be an exact-zero-difference result (Rezd).
- **M(x,y)**: Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
- **p**: The intermediate product having unbounded range and precision.
- **v**: The intermediate result having unbounded range and precision.

For \text{xsmsubasp}, do the following.
- Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[AX].
- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XT].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[BX].

For \text{xsmsubmsp}, do the following.
- Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[AX].
- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[BX].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XT].

src1 is multiplied\(^{1}\) by src3, producing a product having unbounded range and precision.

See part 1 of Table 95, “Actions for xsmsub(a|m)sp”.

src2 is negated and added\(^{2}\) to the product, producing a sum having unbounded range and precision.

The result, having unbounded range and precision, is normalized\(^{3}\).

See part 2 of Table 95, “Actions for xsmsub(a|m)sp”.

The intermediate result is rounded to single-precision using the rounding mode specified by RN.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result as represented in single-precision format. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

---

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.
See Table 63, “VSX Scalar Floating-Point Final Result,” on page 662.

Special Registers Altered

| PPRF | FR | FI |
| FX | OX | UX | XX | VXSNAN | VXISI | VXIMZ |

**Programming Note**

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

**Explanation:**

- `src1`: The double-precision floating-point value in doubleword element 0 of VSR[XA].
- `src2`: For `xsmsubasp`, the double-precision floating-point value in doubleword element 0 of VSR[XT]. For `xsmsubbsp`, the double-precision floating-point value in doubleword element 0 of VSR[XB].
- `src3`: For `xsmsubasp`, the double-precision floating-point value in doubleword element 0 of VSR[XB]. For `xsmsubbsp`, the double-precision floating-point value in doubleword element 0 of VSR[XT].
- `dQNaN`: Default quiet NaN (0x7FF8_0000_0000_0000).
- `NZF`: Nonzero finite number.
- `Rezd`: Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
- `Q(x)`: Return a QNaN with the payload of x.
- `S(x,y)`: Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision. Note: If x = y, v is considered to be an exact-zero-difference result (Rezd).
- `M(x,y)`: Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
- `p`: The intermediate product having unbounded range and precision.
- `v`: The intermediate result having unbounded range and precision.

if ox_flag=1 then SetFX(FPSCR.OX)
if ux_flag=1 then SetFX(FPSCR.UX)
if xx_flag=1 then SetFX(FPSCR.XX)

vx_flag ← vxsnan_flag | vximz_flag | vxisi_flag
vex_flag ← FPSCR.VE & vx_flag

if vex_flag=0 then do
  VSR[VRT+32] ← result
  FPSCR.FPRF ← fprf_CLASS_BFP128(result)
end
FPSCR.FR ← (vx_flag=0) & inc_flag
FPSCR.FI ← (vx_flag=0) & xx_flag

Let \( src1 \) be the floating-point value in \( VSR[VRA+32] \) represented in quad-precision format.

Let \( src2 \) be the floating-point value in \( VSR[VRT+32] \) represented in quad-precision format.

Let \( src3 \) be the floating-point value in \( VSR[VRB+32] \) represented in quad-precision format.

If either \( src1 \), \( src2 \), or \( src3 \) is a Signalling NaN, an Invalid Operation exception occurs and \( VXSNAN \) is set to 1.

If \( src1 \) is an Infinity value and \( src3 \) is a Zero value, or if \( src1 \) is a Zero value and \( src3 \) is an Infinity value, an Invalid Operation exception occurs and \( VXIMZ \) is set to 1.

If \( src2 \) and the product of \( src1 \) and \( src3 \) are Infinity values having same signs, an Invalid Operation exception occurs and \( VXISI \) is set to 1.

If \( src1 \) is a Signalling NaN, the result is the Quiet NaN corresponding to \( src1 \).

Otherwise, if \( src1 \) is a Quiet NaN, the result is \( src1 \).

Otherwise, if \( src2 \) is a Signalling NaN, the result is the Quiet NaN corresponding to \( src2 \).

Otherwise, if \( src3 \) is a Quiet NaN, the result is \( src3 \).

Otherwise, if \( src1 \) is an Infinity value and \( src3 \) is a Zero value, or if \( src1 \) is a Zero value and \( src3 \) is an Infinity value, the default Quiet NaN is set.

Otherwise, if the product of \( src1 \) and \( src3 \), and \( src2 \) are Infinity values having same signs, the result is the default Quiet NaN.

Otherwise, do the following.

1. \( src1 \) is multiplied by \( src3 \), producing a product having unbounded significand precision and exponent range.

2. \( src2 \) is negated and added to the product, producing a sum having unbounded range and precision.

See part 1 of Table 96. "Actions for xmsubqpo[0]."

See part 2 of Table 96. "Actions for xmsubqpo[0]."

If the intermediate result is \( \text{Tiny} \) (i.e., the unbiased exponent is less than \(-16382\) and \( UE=0 \), the significand is shifted right \( N \) bits, where \( N \) is the difference between \(-16382\) and the unbiased exponent of the intermediate result). The exponent of the intermediate result is set to the value \(-16382\).

If \( RO=1 \), let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by \( RN \). Unless the result is an Infinity or a Zero, the intermediate result is rounded to quad-precision using the specified rounding mode.

The result is placed into \( VSR[VRT+32] \) in quad-precision format.

FPFR is set to the class and sign of the result. \( FR \) is set to indicate if the rounded result was incremented. \( FI \) is set to indicate the result is inexact.

If a trap-disabled Invalid Operation exception occurs, \( FR \) and \( FI \) are set to 0.

1. The quad-precision default Quiet NaN is the value, 0x7FFF_8000_0000_0000_0000_0000_0000.
If a trap-enabled Invalid Operation exception occurs, VSR[VRT+32] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 662.

Let XT be the value 32×TX + T.
Let XA be the value 32×AX + A.
Let XB be the value 32×BX + B.

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

src1 is multiplied[1] by src2, producing a product having unbounded range and precision.

The product is normalized[2].

See Table 97.

The intermediate result is rounded to double-precision using the rounding mode specified by RN.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 662.

Special Registers Altered

FPRF FR FI
FX OX UX XX VXSNAN VXIMZ

Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Explanation:
- **src1**: The double-precision floating-point value in doubleword element 0 of VSR[XA].
- **src2**: The double-precision floating-point value in doubleword element 0 of VSR[XB].
- **dQNaN**: Default quiet NaN (0x7FF8_0000_0000_0000).
- **NZF**: Nonzero finite number.
- **M(x, y)**: Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
- **Q(x)**: Return a QNaN with the payload of x.
- **v**: The intermediate result having unbounded significand precision and unbounded exponent range.

Let src1 be the floating-point value in VSR[VRA+32] represented in quad-precision format.

Let src2 be the floating-point value in VSR[VRB+32] represented in quad-precision format.

If either src1 or src2 is a Signalling NaN, an Invalid Operation exception occurs and VXSNAN is set to 1.

If src1 is an Infinity value and src2 is a Zero value, or if src1 is a Zero value and src2 is an Infinity value, an Invalid Operation exception occurs and VXIMZ is set to 1.

If src1 is a Signalling NaN, the result is the Quiet NaN corresponding to src1.

Otherwise, if src1 is a Quiet NaN, the result is src1.

Otherwise, if src2 is a Signalling NaN, the result is the Quiet NaN corresponding to src2.

Otherwise, if src2 is a Quiet NaN, the result is src2.

Otherwise, if src1 is an Infinity value and src2 is a Zero value, or if src1 is a Zero value and src2 is an Infinity value, the result is the default Quiet NaN.

Otherwise, do the following.

The normalized product of src1 multiplied by src2 is produced with unbounded significand precision and exponent range.

See Table 98, "Actions for xsmulqp[o]".

If the intermediate result is Tiny (i.e., the unbiased exponent is less than \(-16382\)) and UE=0, the significand is shifted right \(N\) bits, where \(N\) is the difference between \(-16382\) and the unbiased exponent of the intermediate result. The exponent of the intermediate result is set to the value \(-16382\).

If RO=1, let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by RN. Unless the result is an Infinity or a Zero, the intermediate result is rounded to quad-precision using the specified rounding mode.

The result is placed into VSR[VRT+32] in quad-precision format.

FPRF is set to the class and sign of the result. FR is set to indicate if the rounded result was incremented. FI is set to indicate the result is inexact.

If a trap-disabled Invalid Operation exception occurs, FR and FI are set to 0.

If a trap-enabled Invalid Operation exception occurs, VSR[VRT+32] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result," on page 662.

</tr>
</tbody>
</table>
Let \( XT \) be the value \( 32 \times TX + T \).
Let \( XA \) be the value \( 32 \times AX + A \).
Let \( XB \) be the value \( 32 \times BX + B \).

Let \( src1 \) be the double-precision floating-point value in doubleword element 0 of \( VSR[XA] \).

For \textit{xsnmaddadp}, do the following.
- Let \( src2 \) be the double-precision floating-point value in doubleword element 0 of \( VSR[XT] \).
- Let \( src3 \) be the double-precision floating-point value in doubleword element 0 of \( VSR[XB] \).

For \textit{xsnmaddmdp}, do the following.
- Let \( src2 \) be the double-precision floating-point value in doubleword element 0 of \( VSR[XB] \).
- Let \( src3 \) be the double-precision floating-point value in doubleword element 0 of \( VSR[XT] \).

\( src1 \) is multiplied\(^1\) by \( src3 \), producing a product having unbounded range and precision.

See part 1 of Table 100.

\( src2 \) is added\(^2\) to the product, producing a sum having unbounded range and precision.

The sum is normalized\(^3\).

See part 2 of Table 100.

The intermediate result is rounded to double-precision using the rounding mode specified by \( RN \).

The result is negated and placed into doubleword element 0 of \( VSR[XT] \) in double-precision format.

The contents of doubleword element 1 of \( VSR[XT] \) are set to 0.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, \( VSR[XT] \) and FPRF are not modified, and FR and FI are set to 0.

---

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.
See Table 101, “Scalar Floating-Point Final Result with Negation,” on page 768.

#### Explanation:

- **src1**: The double-precision floating-point value in doubleword element 0 of VSR[XA].
- **src2**: For **xsnmaddadp**, the double-precision floating-point value in doubleword element 0 of VSR[XT].
- **src3**: For **xsnmadddp**, the double-precision floating-point value in doubleword element 0 of VSR[XB].
- **dQNaN**: Default quiet NaN (0x7FF8_0000_0000_0000).
- **NZF**: Nonzero finite number.
- **Rezd**: Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
- **Q(x)**: Return a QNaN with the payload of x.
- **A(x,y)**: Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.
- **M(x,y)**: Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
- **p**: The intermediate product having unbounded range and precision.
- **v**: The intermediate result having unbounded range and precision.

### Explanation:
- The results do not depend on this condition.
- **class(x)** Classifies the floating-point value \(x\) as defined in Table 2, “Floating-Point Result Flags,” on page 505.
- **error()** The system error handler is invoked for the trap-enabled exception if MSR.FE0 and MSR.FE1 are set to any mode other than the ignore-exception mode.
- **fi(x)** FPSCR.FI is set to the value \(x\).
- **fprf(x)** FPSCR.FPRF is set to the 5-bit value \(x\).
- **fr(x)** FPSCR.FR is set to the value \(x\).
- **fx(x)** FPSCR.FX is set to 1 if FPSCR.x=0. FPSCR.x is set to 1.
- \(\beta\) Wrap adjust, where \(\beta = 2^{1536}\) for double-precision and \(\beta = 2^{192}\) for single-precision.
- **q** The value defined in Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 661, significand rounded to the target precision, unbounded exponent range.
- **r** The value defined in Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 661, significand rounded to the target precision, bounded exponent range.
- **v** The precise intermediate result defined in the instruction having unbounded significand precision, unbounded exponent range.
- **n(x)** The value \(x\) is is negated by complementing the sign bit of \(x\).
- **T(x)** The value \(x\) is placed in element 0 of VSR[XT] in the target precision format.

#### Explanation:

- **src1**: The double-precision floating-point value in doubleword element 0 of VSR[XA].
- **src2**: For \texttt{xsnmaddsp}, the double-precision floating-point value in doubleword element 0 of VSR[XT].
- **src3**: For \texttt{xsnmaddmsp}, the double-precision floating-point value in doubleword element 0 of VSR[XB].
- **dQNaN**: Default quiet NaN (0x7FFE_0000_0000_0000).
- **NZF**: Nonzero finite number.
- **Rezd**: Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
- **Q(x)**: Return a QNaN with the payload of x.
- **A(x,y)**: Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.
  
  Note: If x = -y, v is considered to be an exact-zero-difference result (Rezd).
- **M(x,y)**: Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
- **p**: The intermediate product having unbounded range and precision.
- **v**: The intermediate result having unbounded range and precision.
**VSX Scalar Negative Multiply-Add Quad-Precision [using round to Odd] X-form**

\[
xsnmaddqp \text{ VRT, VRA, VRB (} RO=1 \text{)}
\]

Let \( src1 \) be the floating-point value in \( VSR[VRA+32] \) represented in quad-precision format.

Let \( src2 \) be the floating-point value in \( VSR[VRT+32] \) represented in quad-precision format.

Let \( src3 \) be the floating-point value in \( VSR[VRB+32] \) represented in quad-precision format.

If either \( src1 \), \( src2 \), or \( src3 \) is a Signalling NaN, an Invalid Operation exception occurs and VXSNAN is set to 1.

If \( src1 \) is an Infinity value and \( src3 \) is a Zero value, or if \( src1 \) is a Zero value and \( src3 \) is an Infinity value, an Invalid Operation exception occurs and VXIMZ is set to 1.

If \( src2 \) and the product of \( src1 \) and \( src3 \) are Infinity values having opposite signs, an Invalid Operation exception occurs and VXISI is set to 1.

If \( src1 \) is a Signalling NaN, the result is the Quiet NaN corresponding to \( src1 \).

Otherwise, if \( src1 \) is a Quiet NaN, the result is \( src1 \).

Otherwise, if \( src2 \) is a Signalling NaN, the result is the Quiet NaN corresponding to \( src2 \).

Otherwise, if \( src2 \) is a Quiet NaN, the result is \( src2 \).

Otherwise, if \( src3 \) is a Signalling NaN, the result is the Quiet NaN corresponding to \( src3 \).

Otherwise, if \( src3 \) is a Quiet NaN, the result is \( src3 \).

Otherwise, if \( src1 \) is an Infinity value and \( src3 \) is a Zero value, or if \( src1 \) is a Zero value and \( src3 \) is an Infinity value, the result is the default Quiet NaN.

Otherwise, if the product of \( src1 \) and \( src3 \), and \( src2 \) are Infinity values having opposite signs, the result is the default Quiet NaN.

Otherwise, do the following.

\( src1 \) is multiplied by \( src3 \), producing a product having unbounded significand precision and exponent range.

See part 1 of Table 83. "Actions for xsmadd(a|m)dp".

\( src2 \) is added to the product, producing a sum having unbounded range and precision.

See part 2 of Table 83. "Actions for xsmadd(a|m)dp".

If the intermediate result is Tiny (i.e., the unbiased exponent is less than \( -16382 \)) and \( UE=0 \), the significand is shifted right \( N \) bits, where \( N \) is the difference between \( -16382 \) and the unbiased exponent of the intermediate result. The exponent of the intermediate result is set to the value \( -16382 \).

If \( RO=1 \), let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by RN. Unless the result is an Infinity or a Zero, the intermediate result is rounded to quad-precision using the specified rounding mode.

The result is negated and placed into \( VSR[VRT+32] \) in quad-precision format.

FPFR is set to the class and sign of the result. FR is set to indicate if the rounded result was incremented. FL is set to indicate the result is inexact.

---

1. The quad-precision default Quiet NaN is the value, \( 0x7FFF_8000_0000_0000_0000_0000_0000_0000 \).
If a trap-disabled Invalid Operation exception occurs, \( FR \) and \( FI \) are set to 0.

If a trap-enabled Invalid Operation exception occurs, \( VSR[VRT+32] \) and \( FPRF \) are not modified, and \( FR \) and \( FI \) are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 662.

Explanation:
- **src1**: The quad-precision floating-point value in VSR[VRA+32].
- **src2**: The quad-precision floating-point value in VSR[VRT+32].
- **src3**: The quad-precision floating-point value in VSR[VRB+32].
- **dQNaN**: Default quiet NaN (0x7FFF_8000_0000_0000_0000_0000_0000).
- **NZF**: Nonzero finite number.
- **Rezd**: Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
- **quiet(x)**: Return a QNaN with the payload of x.
- **Add(x, y)**: Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.
  - Note: If x = -y, v is considered to be an exact-zero-difference result (Rezd).
- **Mul(x, y)**: Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
- **p**: The intermediate product having unbounded range and precision.
- **v**: The intermediate result having unbounded range and precision.

</tbody>
</table>

xsnmsubadp XT,XA,XB

Let XT be the value 32×TX + T.
Let XA be the value 32×AX + A.
Let XB be the value 32×BX + B.

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[32×AX + A].

For xsnmsubadp, do the following.
– Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[32×TX + T].
– Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[32×BX + B].

For xsnmsubmdp, do the following.
– Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[32×BX + B].
– Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[32×TX + T].

src1 is multiplied by src3, producing a product having unbounded range and precision.

See part 1 of Table 104.

src2 is negated and added to the product, producing a sum having unbounded range and precision.

The sum is normalized.

See part 2 of Table 104.

The intermediate result is rounded to double-precision using the rounding mode specified by RN.

See Table 101, “Scalar Floating-Point Final Result with Negation,” on page 768.

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

</tbody>
</table>

**Explanation:**

**src1** The double-precision floating-point value in doubleword element 0 of VSR[XA].

**src2** For xsnmsubadp, the double-precision floating-point value in doubleword element 0 of VSR[XB].

**src3** For xsnmsubadp, the double-precision floating-point value in doubleword element 0 of VSR[XC].

**dQNaN** Default quiet NaN (0x7FF8_0000_0000_0000).

**NZF** Nonzero finite number.

**Rezd** Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.

**Q(x)** Return a QNaN with the payload of x.

**S(x,y)** Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision. Note: If x = y, v is considered to be an exact-zero-difference result (Rezd).

**M(x,y)** Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.

**p** The intermediate product having unbounded range and precision.

**v** The intermediate result having unbounded range and precision.
VSX Scalar Negative Multiply-Subtract Type-A
Single-Precision XX3-form

```
xsnmsubasp  XT,XA,XB

0  6  11  16  21  145
   60  T  A  B
```

VSX Scalar Negative Multiply-Subtract Type-M
Single-Precision XX3-form

```
xsnmsubmsp  XT,XA,XB

0  6  11  16  21  153
   60  T  A  B
```

Let XT be the value 32×TX + T.
Let XA be the value 32×AX + A.
Let XB be the value 32×BX + B.

For `xsnmsubasp`, do the following.
- Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].
- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XT].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

For `xsnmsubmsp`, do the following.
- Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].
- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XT].

src1 is multiplied\(^1\) by src3, producing a product having unbounded range and precision.

See part 1 of Table 105, “Actions for xsnmsub(a|m)sp,” on page 781.

src2 is negated and added\(^2\) to the product, producing a sum having unbounded range and precision.

The sum is normalized\(^3\).

See part 2 of Table 105, “Actions for xsnmsub(a|m)sp,” on page 781.

The intermediate result is rounded to single-precision using the rounding mode specified by RN.

The result is negated and placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result as represented in single-precision format. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.
See Table 101, “Scalar Floating-Point Final Result with Negation,” on page 768.

Part 1: Multiply

Explanation:

- src1: The double-precision floating-point value in VSR[XA].dword[0].
- src2: The double-precision floating-point value in VSR[XT].dword[0].
- src3: The double-precision floating-point value in VSR[XB].dword[0].
- dQNaN: Default quiet NaN (0x7FF8_0000_0000_0000).
- NZF: Nonzero finite number.
- Rezd: Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
- Q(x): Return a QNaN with the payload of x.
- S(x,y): Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision. Note: If x = y, v is considered to be an exact-zero-difference result (Rezd).
- M(x,y): Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
- p: The intermediate product having unbounded range and precision.
- v: The intermediate result having unbounded range and precision.

Chapter 7. Vector-Scalar Extension Facility 781
VSX Scalar Negative Multiply-Subtract Quad-Precision [using round to Odd] X-form

\[
x_{\text{snmsubp}} \quad \text{VRT, VRA, VRB} \\
x_{\text{snmsubpq}} \quad \text{VRT, VRA, VRB}
\]

src2 & = \text{bfp\_CONVERT\_FROM\_BFP128}(\text{VSR}[\text{VRT}+32]) \\
src3 & = \text{bfp\_CONVERT\_FROM\_BFP128}(\text{VSR}[\text{VRB}+32]) \\
v & = \text{bfp\_MULTIPLY\_ADD}(src1, src3, \text{bfp\_NEGATE}(src2)) \\
\text{rnd} & = \text{bfp\_NEGATE}(\text{bfp\_ROUND\_TO\_BFP128}(\text{RO}, \text{FPSCR.RN}, v)) \\
\text{result} & = \text{bfp128\_CONVERT\_FROM\_BFP128}(\text{rnd})
\end{align*}
\]

if vxsnan_flag=1 then SetFX(FPSCR.VXSNAN)
if vximz_flag=1 then SetFX(FPSCR.VXIMZ)
if vxisi_flag=1 then SetFX(FPSCR.VXISI)
if ox_flag=1 then SetFX(FPSCR.OX)
if ux_flag=1 then SetFX(FPSCR.UX)
if xx_flag=1 then SetFX(FPSCR.XX)

\[
\begin{align*}
\text{vx\_flag} & \leftarrow vxsnan\_flag \mid vximz\_flag \mid vxisi\_flag \\
\text{ex\_flag} & \leftarrow \text{FPSCR.VE} \mid \text{vx\_flag}
\end{align*}
\]

if ex_flag=0 then do

\[
\begin{align*}
\text{VSR}[\text{VRT}+32] & \leftarrow \text{result} \\
\text{FPSCR.FR} & \leftarrow (\text{vx\_flag}=0) \land \text{inc\_flag} \\
\text{FPSCR.FI} & \leftarrow (\text{vx\_flag}=0) \land \text{vx\_flag}
\end{align*}
\]

Let \( src1 \) be the floating-point value in \( \text{VSR}[\text{VRA}+32] \) represented in quad-precision format.

Let \( src2 \) be the floating-point value in \( \text{VSR}[\text{VRT}+32] \) represented in quad-precision format.

Let \( src3 \) be the floating-point value in \( \text{VSR}[\text{VRB}+32] \) represented in quad-precision format.

If either \( src1 \), \( src2 \), or \( src3 \) is a Signalling NaN, an Invalid Operation exception occurs and VXSNAN is set to 1.

If \( src1 \) is an Infinity value and \( src3 \) is a Zero value, or if \( src1 \) is a Zero value and \( src3 \) is an Infinity value, an Invalid Operation exception occurs and VXIMZ is set to 1.

If \( src2 \) and the product of \( src1 \) and \( src3 \) are Infinity values having same signs, an Invalid Operation exception occurs and VXISI is set to 1.

If \( src1 \) is a Signalling NaN, the result is the Quiet NaN corresponding to \( src1 \).

Otherwise, if \( src1 \) is a Quiet NaN, the result is \( src1 \).

Otherwise, if \( src2 \) is a Signalling NaN, the result is the Quiet NaN corresponding to \( src2 \).

Otherwise, if \( src3 \) is a Quiet NaN, the result is \( src3 \).

Otherwise, if \( src1 \) is an Infinity value and \( src3 \) is a Zero value, or if \( src1 \) is a Zero value and \( src3 \) is an Infinity value, the result is the default Quiet NaN.[1]

Otherwise, if the product of \( src1 \) and \( src3 \), and \( src2 \) are Infinity values having same signs, the result is the default Quiet NaN.

Otherwise, do the following.

\( src1 \) is multiplied by \( src3 \), producing a product having unbounded significand precision and exponent range.

See part 1 of Table 96, "Actions for xsnmsubp[0]".

\( src2 \) is negated and added to the product, producing a sum having unbounded range and precision.

See part 2 of Table 96, "Actions for xsnmsubpq[0]".

If the intermediate result is Tiny (i.e., the unbiased exponent is less than \(-16382\)) and UE=0, the significand is shifted right \( N \) bits, where \( N \) is the difference between \(-16382\) and the unbiased exponent of the intermediate result. The exponent of the intermediate result is set to the value \(-16382\).

If \( RO=1 \), let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by RN. Unless the result is an Infinity or a Zero, the intermediate result is rounded to quad-precision using the specified rounding mode.

The result is negated and placed into \( \text{VSR}[\text{VRT}+32] \) in quad-precision format.

FPFR is set to the class and sign of the result. FR is set to indicate if the rounded result was incremented. FI is set to indicate the result is inexact.

If a trap-disabled Invalid Operation exception occurs, FR and FI are set to 0.

---

[1] The quad-precision default Quiet NaN is the value, \( \text{x}7FFFF_0000_0000_0000_0000_0000_0000 \).
If a trap-enabled Invalid Operation exception occurs, 
\( \text{VSR}[\text{VRT}+32] \) and \( \text{FPRF} \) are not modified, and \( \text{FR} \) and \( \text{FI} \) are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 662.

</tbody>
</table>

**QNaN & src1 is a NaN**

- v ← p

**QNaN & src1 not a NaN**

- v ← src2
- Vxsnan_flag ← 1

---

**Explanation:**

- **src1**: The quad-precision floating-point value in `VSR[VR+32]`
- **src2**: The quad-precision floating-point value in `VSR[VR+32]`
- **src3**: The quad-precision floating-point value in `VSR[VR+32]`
- **QNaN**: Default quiet NaN (0x7FFF_8000_0000_0000_0000_0000_0000)
- **NZF**: Nonzero finite number.
- **Rezd**: Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
- **quiet(x)**: Return a QNaN with the payload of x.
- **sub(x, y)**: Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision.
  - Note: If x = y, v is considered to be an exact-zero-difference result (Rezd).
- **Mul(x, y)**: Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
- p: The intermediate product having unbounded range and precision.
- v: The intermediate result having unbounded range and precision.

FPSCR.FI ← 0b0
```

Let XT be the value $32 \times TX + T$.
Let XB be the value $32 \times BX + B$.

Let `src` be the double-precision floating-point value in doubleword element 0 of `VSR[XB]`.

`src` is rounded to an integer using the rounding mode Round to Nearest Away.

The result is placed into doubleword element 0 of `VSR[XT]` in double-precision format.

The contents of doubleword element 1 of `VSR[XT]` are set to 0.

`FPRF` is set to the class and sign of the result. `FR` is set to 0. `FI` is set to 0.

If a trap-enabled invalid operation exception occurs, `VSR[XT]` and `FPRF` are not modified, and `FR` and `FI` are set to 0.

Special Registers Altered

`FPRF FR=0b0 FI=0b0 VXSNAN`

Programming Note

This instruction can be used to operate on a single-precision source operand.

---

Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

Let src be the floating-point value in VSR[VRT+32] represented in quad-precision format.

If src is a Signalling NaN, an Invalid Operation exception occurs, VXSNAN is set to 1, and the result is the Quiet NaN corresponding to the Signalling NaN.

Otherwise, if src is a Quiet NaN, an Infinity, or a Zero, then the result is src.

Otherwise, src is rounded to an integer using the rounding mode rmode.

The result is placed into VSR[VRT+32] in quad-precision format.

FPRF is set to the class and sign of the result.

For xsrqi, FR is set to 0, FI is set to 0, and XX is not set by an Inexact exception.

For xsrqpix, FR is set to indicate if the result was incremented when rounded, FI is set to indicate the result is inexact, and XX is set by an Inexact exception.

If a trap-disabled Invalid Operation exception occurs, FPRF is set to an undefined value.

If a trap-enabled Invalid Operation exception occurs, VSR[VRT+32] and FPRF are not modified.

Special Registers Altered:

Let $\text{src}$ be the floating-point value in $\text{VSR}[\text{VRB}+32]$ represented in quad-precision format.

If $\text{src}$ is a Signalling NaN, an Invalid Operation exception occurs, $\text{VXSNAN}$ is set to 1, and the result is the Quiet NaN corresponding to the Signalling NaN, with the significand truncated to double-extended-precision.

Otherwise, if $\text{src}$ is a Quiet NaN, then the result is $\text{src}$ with the significand truncated to double-extended-precision.

Otherwise, if $\text{src}$ is an Infinity or a Zero, the result is $\text{src}$.

Otherwise, $\text{src}$ is rounded to double-extended precision (i.e., 15-bit exponent range and 64-bit significand precision) using the specified rounding mode.

The result is placed into $\text{VSR}[\text{VRT}+32]$ in quad-precision format.

$\text{FPRF}$ is set to the class and sign of the result. $\text{FR}$ is set to indicate if the rounded result was incremented. $\text{FI}$ is set to indicate the result is inexact.

If a trap-disabled Invalid Operation exception occurs, $\text{FPRF}$ is set to an undefined value, and $\text{FR}$ and $\text{FI}$ are set to 0.

If a trap-enabled Invalid Operation exception occurs, $\text{VSR}[\text{VRT}+32]$ and $\text{FPRF}$ are not modified, and $\text{FR}$ and $\text{FI}$ are set to 0.

Let src be the floating-point value in VSR[VRT+32] represented in quad-precision format.

If src is a Signalling NaN, an Invalid Operation exception occurs and VXSNAN is set to 1.

If src is a negative, non-zero value, an Invalid Operation exception occurs and VXSQRT is set to 1.

If src is a Signalling NaN, the result is the Quiet NaN corresponding to src.

Otherwise, if src is a Quiet NaN, the result is src.

Otherwise, if src is a negative value, the result is the default Quiet NaN[1].

Otherwise, do the following.

The normalized square root of src is produced with unbounded significand precision and exponent range.

See Table 108, “Actions for vsqrtqp[0],” on page 804.

If RO=1, let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by RN. Unless the result is an Infinity or a Zero, the intermediate result is rounded to quad-precision using the specified rounding mode.

See Section 7.3.2.6, “Rounding” on page 518 for a description of rounding modes.

If there is loss of precision, an Inexact exception occurs.

The result is placed into VSR[VRT+32] in quad-precision format.

FPRF is set to the class and sign of the result. FR is set to indicate if the rounded result was incremented. FI is set to indicate the result is inexact.

If a trap-disabled Invalid Operation exception occurs, FPRF is set to an undefined value, and FR and FI are set to 0.

If a trap-enabled Invalid Operation exception occurs, VSR[VRT+32] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 662.

**Explanation:**

- **src**: The double-precision floating-point value in doubleword element 0 of VSR[XB].
- **dQNaN**: Default quiet NaN (0x7FF8_0000_0000_0000).
- **NZF**: Nonzero finite number.
- **SQRT(x)**: The unbounded-precision and exponent range square root of the floating-point value x.
- **Q(x)**: Return a QNaN with the payload of x.
- **v**: The intermediate result having unbounded significand precision and unbounded exponent range.

| FPSCR.FR | ← | inc_flag |
| FPSCR.FI | ← | xx_flag |
end else do
| FPSCR.FR | ← | 0b1 |
| FPSCR.FI | ← | 0b1 |
end

Let \( XT \) be the value \( 32×TX + T \).
Let \( XA \) be the value \( 32×AX + A \).
Let \( XB \) be the value \( 32×BX + B \).

Let \( src1 \) be the double-precision floating-point value in doubleword element 0 of VSR[AX].

\( src2 \) is negated and added to \( src1 \), producing a sum having unbounded range and precision.

See Table 110.

The intermediate result is rounded to double-precision using the rounding mode specified by RN.

The result is placed into doubleword element 0 of VSR[XT].

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, "VSX Scalar Floating-Point Final Result," on page 662.

Special Registers Altered

\( \text{FPRF} \) \( \text{FR} \) \( \text{FI} \) \( \text{FX} \) \( \text{OX} \) \( \text{UX} \) \( \text{XX} \) \( \text{VXSNAN} \) \( \text{VXISI} \)

Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

---

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.

2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

### Explanation:
- **src1**: The double-precision floating-point value in doubleword element 0 of VSR[XA].
- **src2**: The double-precision floating-point value in doubleword element 0 of VSR[XB].
- **dQNaN**: Default quiet NaN (0x7FF8_0000_0000_0000).
- **NZF**: Nonzero finite number.
